SUBJECT: Overall Final EAO Water Information Request Response Summary

Dear Ms. Ferbey:

Telkwa Mining Limited (Telkwa Mining) is pleased to provide an overall summary of our final EAO Water Information Request response summary and organization which proivdes the complete respoonse to the EAO water IR as follows:

ATTACHMENT A provides the January 29, 2026 that represents the Water Information that was approved for submission after discussions with the EAO and the line agencies of Ministry of Environment and Parks (MENV) and Minsitry of Mining and Critical Minerals (MMCM) on the September 15, 2026 EAO Water IR submission for review.

ATTACHMENT B provides the response to the follow up information requests from MENV on April 15, 2026.

ATTACHMENT C provides the response to the follow up information requests from MMCM on May 15, 2026.

ATTACHMENT D provides the response to the follow up information request 8 and 9 from MENVe on May 22, 2026.

ATTACHMENT E provides the response to the follow up Information request 8 from MENV and MMCM on June 25, 2026.

If you have any questions please do not hesitate to contact Dan Farmer at 604-220-5703 or dan.farmer@telkwa-mining.ca.

Sincerely,

Daniel J. Farmer
Project and Development Manager
Telkwa Mining Limited

FROM: Dan Farmer, Project, and Development Manager, Telkwa Mining Limited

DATE: January 29, 2026

SUBJECT: **Tenas Project Water Quality EAO Information Request Response**

0. INTRODUCTION

In response to the Information Request (IR) related to water dated November 23, 2022, for Telkwa Mining Limited's (Telkwa Mining) Tenas Project's (Project) Environmental Assessment Certificate (EAC) Application submitted in early 2022 please find Telkwa Mining's response to the questions raised by the British Columbia Environmental Assessment Office (BC EAO) working group.

As part of Telkwa Mining's commitment to undertake additional water flow monitoring for Four, Goathorn, and Tenas Creeks as recommended by SRK Consulting (Canada) Inc. (SRK), the water and load balance model (WLBM) has been updated to reflect the water monitoring completed in 2021 and 2022 for these creeks, see **Appendix 1: Tenas Project, Water and Load Balance Modeling Report (Updated 2025), SRK**. In summary the following was found:

- Goathorn Creek high flows were underestimated by the WLBM provided by the EAC Project Case (August 2022). Low flows were slightly overestimated by the WLBM provided by the EAC Project Case (August 2022), so low flows were reduced for Goathorn Creek in the Final EAC Project Cases (2024).
- Tenas Creek flows measured were comparable to the EAC Project Case (August 2022) for low and high flows and if anything were underestimated by the EAC Project Case (August 2022) model, so the parameter concentrations provided were conservative. High flows were updated for Tenas Creek but no change to low flows were made as part of the Final EAC Project Cases (2024).
- Four Creek flows measured were again comparable to the EAC Project Case (2022) for low and high flows and if anything were underestimated by the EAC Project Case

(August 2022) model. High flows were updated for Four Creek but no change to low flows were made as part of the Final EAC Project Cases (2024).

Additional years of precipitation data have been gathered since the EAC Application was submitted, and it was found that precipitation values in the EAC Project Case (August 2022) model were under reporting annual precipitation values, so these were increased in the Updated and Final EAC Project Cases (2024) versus the EAC Project Case (August 2022)'s WLBM. Please see **Appendix 2: Tenas Project, Hydrometeorological Baseline and Model Development Report (Update 2025), SRK**. Telkwa Mining continued monitoring for Four, Tenas, and Goathorn Creeks in October 2023, and will review stream flow levels again if the Project moves into the permitting process.

Telkwa Mining commenced an acid rock drainage (ARD) barrel program in late 2019 to better understand the potential ARD and metal leaching (ML) characteristics of the material rock zones and overburden recovered within the EA Open Pit. Telkwa Mining has continued testing material seepage from these barrels since 2019. Key observations based on this testing is as follows:

- Only one of the potentially acid generating (PAG) barrels (Barrel 6) has gone **acidic after approximately 4 years** of monitoring. The onset of acidic drainage under field conditions may be accelerated because the barrel samples have been crushed to minus 1/4 inch (8 millimetres [mm]) as the material was the same as used in the humidity cells. There will be a mixture of grain sizes in the commercial operation with several grains much larger than the barrel material size. In addition, the barrel contains a mixture of rock from Zones 6, and 7 and had a weighted Neutralizing Potential Ratio (NPR) of Neutralizing Potential (NP) to Acid Potential (AP) of 0.55. The average weighted NPRs of Zones 6, and 7 in the drillhole database were 1.8 and 1.7, respectively (SRK 2025). The material in Barrel 6 therefore provides a conservative estimate of the lag time to the formation of acidic conditions.
- The source terms for some parameters were overstated (higher concentrations) while others were understated (lower concentrations) in the water and load balance provided in the EAC Project Case (August 2022) based on the laboratory measurements of the effluent collected from these barrels due to assumed scaling factors that were not site-specific. SRK developed updated source terms for *non-PAG* rock, PAG rock Flush term, EA Open Pit Walls, and overburden using the barrel results provided in: **Appendix 3: Geochemical Field Barrel Results Interpretation, Tenas Project, SRK;** and **Appendix 4: Updated Water Quality Source Terms, SRK.**

These source terms were further reviewed and modified for the *non-PAG* rock backfilled into the EA Open Pit by Okane Consultants using a more detailed model that accounted for dimensionality in the *non-PAG* rock backfill (backfill) and oxygen convection and diffusion for several different cover scenarios. Okane Consultants developed a distributed 3-dimensional model focused on

water infiltration and storage, and oxygen levels based on the material properties and the rock backfill pile construction methodology employed by the Project with their report included in **Appendix 5: Tenas Project - Suboxic Evaluation of Non-Acid Generating Mine Rock, Okane**. This modelling exercise modified the source terms for parameters being potentially leached from the backfill and was used for the Final EAC Project Case (2024).

Several updates were made in the water and load balance model since the EAC Project Case (August 2022). The new Project Case was titled "Final EAC Project Case (2024) (as found in **Appendix 1, Tenas Project, Water and Load Balance Modeling Report (Updated 2025), SRK)**, and the integrated changes are described as follows:

- Incorporate the effects of progressive reclamation and backfill/dam/buttress development (for progressively covered areas of *non-PAG*).
- Use of seasonal background parameter concentrations (50th percentile) to reflect the seasonality of the background/baseline parameter quality concentrations related to winter (November to March) and summer (April to October) seasons to develop predicted concentrations from the Project more accurately in the receiving environment.
- Incorporation of blasthole liners for the source control of nitrogen species. This Best Management Practice (BMP) was identified through the additional mitigations assessment.
- Revision of how downstream parameter concentrations in relation to groundwater seepage was calculated based on updated values from the hydrogeological model and to account for dilution from non-contact groundwater to the streams.
- Updates to reflect the recently published climate change models from 2023 versus the 2018 versions that were used in the EAC Project Case (August 2022).

Through the Best Achievable Technology (BAT) assessment, it was determined that the introduction of water treatment through In-situ Active Gravel Bed Reactors (GBR) and/or active water treatment using Reverse Osmosis with an Anaerobic Bioreactor and High-Density Sludge Lime Treatment were not recommended but should only be incorporated using a Trigger Action Response Plan based on site monitoring during all phases of the Project. Further information on the Final EAC Project Case (2024) can be found under **Theme 1**.

Error! Not a valid bookmark self-reference. below provides a summary of the EAC Project Case (August 2022) and the Final EAC Project Case (2024) for parameters that were exceeding water quality guidelines for the EAC Project Case (August 2022). As demonstrated the Final EAC Project Case (2024) does not have exceedances in the receiving environment except for parameters that are already in exceedance for background conditions and a short duration (4 year) exceedance of cobalt in Four Creek which is likely not to occur if attenuation mechanisms in groundwater were accounted for in the water model.

Table 0-1: Water Quality (Maximum Monthly Mean) Results for the EAC Project Case (August 2022) and the Final EAC Project Case (2024) in Post-Closure at Relevant Prediction Nodes Using Expected Source Terms and Average Hydrology Conditions

Location Creek	Parameter	BC WQG (2025) (mg/L)	EAC Project Case (August 2022) (mg/L)	Final EAC Project Case (2024) (mg/L)
WQSEA1 Goathorn Creek	Copper (d)	0.0013	Not Available	0.0016
WQS06 Goathorn Creek	Copper (d)	0.0013	0.0019	0.0016
WQS03_DS Four Creek	Cadmium (d)	0.00023	0.00026	0.000012
	Cobalt (d)	0.00050	0.00066	0.00063
	Nitrite (t)	0.020	0.038	0.0090
	Sulfate (t)	309	360	33
	Selenium (t)	0.0020	0.0058	0.00081
WQS04 Tenas Creek	Cobalt (d)	0.00045	0.00082	0.00029
	Copper (d)	0.0026	0.0031	0.0013
	Nickel (d)	0.0025	0.0031	0.00063
	Nitrite (t)	0.020	0.045	0.0056
	Sulfate (t)	218	260	24
	Selenium (t)	0.0020	0.0041	0.00079

Notes: BC=British Columbia; EAC=Environmental Assessment Certificate; mg/L=milligrams per litre; WQG=water quality guideline.
Red text indicates exceedances of WQGs.
Please note that dissolved copper exceeds the WQGs under background conditions.

1. INFORMATION REQUEST (IR) THEMES 1-8

The IRs provided by the EAO have been grouped into a series of themes for subsequent discussion.

- **Theme 1**: Design alternative treatment options and/or provide additional mitigation measures which are capable of meeting BC Chronic Water Quality Guidelines for the Protection of Aquatic Life (BC WQGs) near appropriately sited discharge locations;
- **Theme 2**: Substantially review the Water Balance Model. The Water Balance Model is key to assessing mitigations against effects to many Valued Components not only water quality;
- **Theme 3**: Have a Qualified Professional (QP) identify lentic areas in the receiving environment which may receive selenium from mine operations, and ensure that background concentrations of selenium in water, sediment, invertebrate, and fish tissues are collected and compiled in those lentic areas;
- **Theme 4**: Conduct additional water quality predictions using recent sensitivity analysis of the semi-permeable pond liner;
- **Theme 5**: Ensure all planned discharges are incorporated into the Water Balance Model and water quality predictions;
- **Theme 6**: Other comments not specified in BC EAO's IR request letter, but provided in the ITT table;
- **Theme 7**: EMLI Geoscience clarifications and information requests; and,
- **Theme 8**: EMLI Geotechnical clarifications and information requests.

Please note:

The order in which the themes are addressed is not the same as the list specified above since Themes 5, and 2 need to be completed prior to commencing Theme 1 which entails a BAT assessment to review alternative treatment technologies/additional mitigations as it is dependent on the WLBM being accepted and understood by the Working Group as it forms the basis of the BAT assessment.

2. RESPONSES TO INFORMATION REQUEST THEMES 1 THROUGH 8

THEME 5: ENSURE ALL PLANNED DISCHARGES ARE INCORPORATED INTO THE WATER BALANCE MODEL AND WATER QUALITY PREDICTIONS

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

The WLBM is missing data from all planned discharges.

507 ITT TABLE AND 516 ITT TABLE

Table 6.2-1 of the Discharge MP lists many surface discharges that are not incorporated into the Water and Load Balance Model. The WLBM application considers the discharges from the Tenas Control Pond, the Management Ponds, and the Rail Infrastructure Pond. For all other discharges, please indicate where each is characterized in the application including source term assessment, water quality predictions, frequency and duration of discharge, mitigation strategies (include liner permeability where applicable), identification of parameters of concern, and residual effects assessment. For all unlined ponds and other discharges to ground, evaluate the discharge following the guidance in ENV "Authorizing Point and Non-point source discharges to ground" (https://www2.gov.bc.ca/assets/gov/environment/waste-management/industrial-waste/industrial-waste/mining-smelt-energy/guidance-documents/7276_env_rob_dtg_factsheet.pdf) [EA Information Requirement].

IR LETTER NEW AND 516 ITT TABLE

Table 6.2-1 of the Discharge Management Plan lists many surface discharges that are not incorporated into the WLBM. The WLBM application considers the discharges from the Tenas Control Pond, the Management Ponds, and the Rail Infrastructure Pond.

1. *For all other discharges, indicate where each is characterized in the Application, including: source term assessment; water quality predictions; frequency and duration of discharge; mitigation strategies (include liner permeability where applicable); identification of parameters of concern; and residual effects assessment.*
2. *For all unlined ponds and other discharges to ground, evaluate the discharge following the guidance in ENV's Authorizing Point and Non-point source discharges to ground.*

RESPONSE 507 ITT TABLE AND 516 ITT TABLE

This IR request stems from the fact that some of the sedimentation ponds that discharge to ground were not included as part of the WLBM in the EAC Application prepared by SRK and presented in **Appendix 1.0-E Water and Load Balance Modeling Report of the Environmental Assessment Certificate (EAC) Application**. Specifically, the following sedimentation ponds were not included in the overall WLBM:

- Explosive Facility;
- Explosive Magazine;
- Rock Quarry;
- Gravel Quarry 1 and 2; and,
- East and West TAC.

The Explosive Facility, and Rock Quarry sedimentation ponds are lined with impermeable geomembrane liners or equivalent while the remaining sedimentation ponds are unlined.

The reasons why these sedimentation ponds were not considered in the site WLBM when it was developed were:

- They are geographically separate from the EA Open Pit, management and control ponds, and material storage pile water management systems.
- These sedimentation ponds are small and were developed to manage very defined catchments which are not connected to overall water management system for the open pit and material storage structures and have very low flow rates compared to the discharge from mine components through the Tenas Control Pond.
- These sedimentation ponds are expected to only discharge during freshet and storm events as their watersheds are small and defined.
- These sedimentation ponds collect water from inert material such as gravels and soils currently exposed within their catchment area.
- Total Suspended Solids (TSS) is the main parameter of concern for majority of these sedimentation ponds excluding the Explosive Facility and Rock Quarry Sedimentation Ponds where nitrogen species are also potential parameters of concern.
- To control TSS, the sedimentation ponds have been designed according to BC ENV *Technical Guidance 7: Assessing Design Size and Operation of Sediment Ponds* (December 2015). The sedimentation ponds are designed to produce a monthly mean maximum TSS level of 35 mg/L to align with the proposed federal *Coal Mine Effluent Regulations* which is considered protective of the receiving environment.

POND DESCRIPTIONS

The Explosive Magazine Sedimentation Pond captures run off from a 50 by 50-metre (m) pad where the three (3) explosive magazine steel buildings are located. The pad is comprised of crushed gravel at a 1% grade leading to the sedimentation pond. TSS is the only parameter of concern for this pond as no blasting agents are being offloaded or loaded at this location. Furthermore, traffic volumes (4 to 6 trips on dayshift only) at this location will be low as only authorized personnel are permitted to access this location. Only packaged explosive products and blasting accessories are stored at this location inside weatherproof steel buildings and no bulk explosive products are delivered to this location so there is little chance of a spill releasing nitrogen species to the environment. The water discharged from this sedimentation pond will be to the ground via a controlled pumping system and from seepage from the floor of the pond itself.

The Explosive Facility Sedimentation Pond captures run off from a 100 by 100-m pad comprised of crushed gravel at 1 percent (%) grade leading to the sedimentation pond where the one (1)

silo of emulsion (35 tonnes) and one (1) silo of Ammonium Nitrate Prill (50 tonnes) are stored. A closed loop wash bay / maintenance building for washing and maintaining the explosive transport trucks provided by the authorized explosive vendor is also located at this pad. The two parameters of concern identified for this pond are TSS and nitrogen species from potential spills of ammonium nitrate (AN) prill and/or emulsion blasting agents on the pad. This sedimentation pond is lined with a bituminous liner or equivalent and will discharge to ground via a controlled pumping system. Monitoring of the water in the sedimentation pond will be completed in compliance with regulatory approvals and if nitrate/nitrite/ammonia concentrations are above permit approved limits the water will be pumped to the onsite evaporator which is part of the wash bay/maintenance building for the Explosive Facility for treatment. The precipitate will either be shipped offsite for disposal at an approved and licensed facility or combined with blasting agents for detonation as part of the blasting process. In the permitting phase the Explosive Facility Pad and Magazine Pad will be combined into one site with a size of 100 by 100-m thereby reducing the two sedimentation ponds in the EAC application to one for permitting.

The two (2) sedimentation ponds for the Gravel Quarry only collect contact water from activities involving disturbing overburden materials, sands, gravels, and water in contact with gravel from the existing approved Quarry. The two Gravel Quarry Sedimentation Ponds service distinct phases of the Gravel Quarry already approved by Ministry of Mines and Critical Minerals (MCMM) and operated by Telkwa Mining. The two Gravel Quarry Sedimentation Ponds service small catchment areas associated with two gravel pits that will produce approximately 35,000 cubic metres (m^3) of material over the life of the Quarries which is approximately 10 years. These two sedimentation ponds will not operate concurrently, rather the Gravel Quarry Sedimentation Pond 1 will operate for roughly four (4) years until the Gravel Quarry 1 area is exhausted and will be reclaimed and then the Gravel Quarry Sedimentation Pond 2 will operate for the remaining six (6) years until the Gravel Quarry 2 area is exhausted. Furthermore, these ponds will also not be used year around but will only be required during when the quarries are active between Jun and September of the first 10 years. Based on the static geochemical test work conducted for the Rock Quarry, Gravel Quarries, and Tenas Access Corridor (TAC), the overburden and rock materials draining to these sedimentation ponds are *non-PAG* material using an NPR cut off of 2 to 1; however, these materials will be subject to verification testing as detailed in the **Metal Leaching/Acid Rock Drainage (ML/ARD) Management Plan (S13.0-C12)** of the **EAC Application**. These ponds only operate during the first 10 years of the Operation Phase at which time both phases of the gravel quarry are exhausted and reclaimed including the sedimentation ponds.

The two (2) sedimentation ponds adjacent to Goathorn Creek are constructed in support of the **Construction Environmental Management Plan (CEMP) (S13.0-S4)** of the **EAC Application** to provide contingency sedimentation capacity for construction activities being undertaken in this valley on both sides of Goathorn Creek. Again, these two sedimentation ponds only service small

catchment areas on either side of Goathorn Creek (approximately 1 hectare [ha] on each side) and will treat contact water from cut and fill activities taking place if already implemented sediment and erosion control measures are insufficient. Again, TSS is the only parameter of concern as only surficial materials are being disturbed by improvements to the Forest Service Roads (FSRs) and no blasting is envisioned for road construction activities in the Goathorn Creek Valley. As these ponds are constructed primarily in highly permeably material, water discharge from these facilities will be to ground either from the base of the ponds. Once the Construction Phase is complete and the reclamation of the cut and fill slopes for the TAC is complete, these ponds will be decommissioned and reclaimed. The materials excavated and disturbed within the Goathorn Creek Valley have been evaluated and been determined to be *non-PAG* using an NPR cut off of 2.0 to 1; however, these materials excavated will be subject to verification testing as detailed in the **Metal Leaching/Acid Rock Drainage (ML/ARD) Management Plan (S13.0-C12)** of the **EAC Application**.

The Rock Quarry Sedimentation Pond services the catchment of Rock Quarry activities roughly 2.5 ha in size and located 7 kilometres (kms) west of the mine site. The materials have been evaluated and been determined to be *non-PAG* using an NPR cut off of 2.0 to 1. This material will be subject to verification testing of blastholes and/or free dig material as specified in the **Metal Leaching/Acid Rock Drainage (ML/ARD) Management Plan (S13.0-C12)** of the **EAC Application**. The Rock Quarry will only be developed once the gravel quarries are completed which is estimated to occur in Year 10 so the Rock Quarry and two Gravel Sedimentation Ponds will not be in operation concurrently. The two parameters of concern identified for this Rock Quarry were TSS and nitrogen species and it will also discharge to ground and is not lined. Roughly 45,000 m^3 of material will be excavated for road surfacing materials over its 12-year life. Monitoring of the water in the Rock Quarry Sedimentation Pond will be completed in compliance with regulatory approvals.

Table 2-1 below summarizes the operating periods of the various sedimentation ponds not included in the overall WLBM.

Figure 2-1 through **Figure 2-6** illustrate the location of the various sedimentation ponds during four time periods associated with the Project: Construction Phase, Operation Phase Years 1 to 4, Operation Phase Years 5 to 10, Operation Phase Years 11 to 21, Decommissioning and Reclamation Phase, and the Post-closure phase.

Table 2-1: Summary of Operating Timeframes for Sedimentation Ponds not Included in the WLBM

Period	Explosive Facility Sedimentation Pond	Explosive Magazine Sedimentation Pond	Goathorn East and West Sedimentation Ponds	Gravel Quary 1 Sedimentation Pond	Gravel Quarry 2 Sedimentation Pond	Rock Quarry Sedimentation Pond
Construction Phase	No	No	Yes	No	No	No
Years 0 to 4	Yes	Yes	No	Yes	No	No
Years 5 to 10	Yes	Yes	No	No	Yes	Yes
Years 11 to 21	Yes	Yes	No	No	No	Yes
Decommissioning and Reclamation Phase	No	No	No	No	No	No
Post-closure Phase	No	No	No	No	No	No

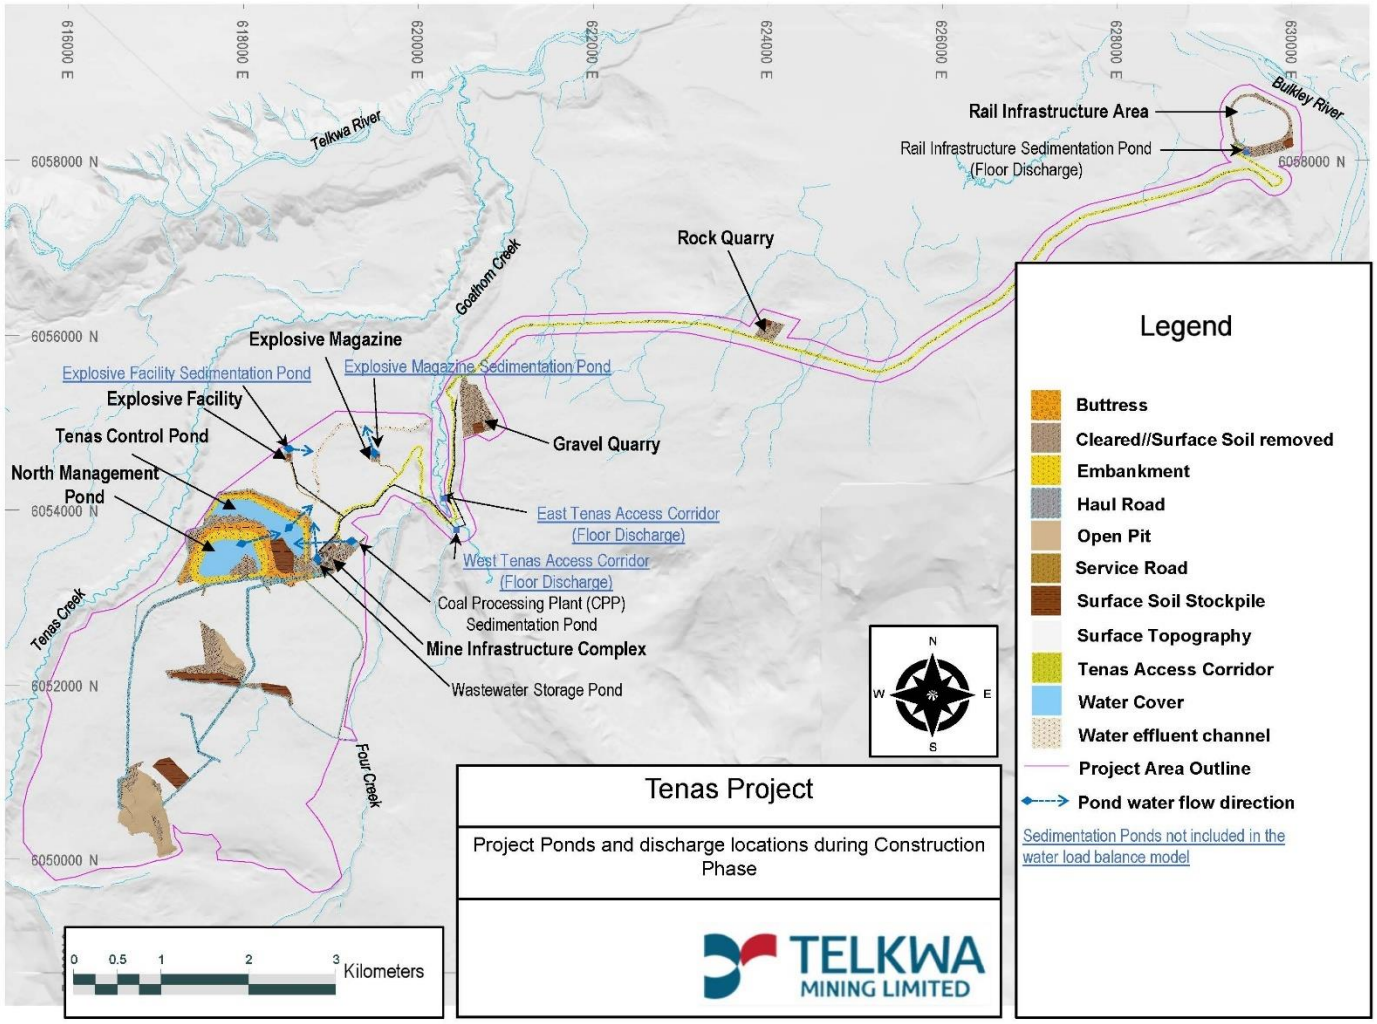

Figure 2-1: Sedimentation Ponds Location and Operation During Construction Phase not Included in WLBM

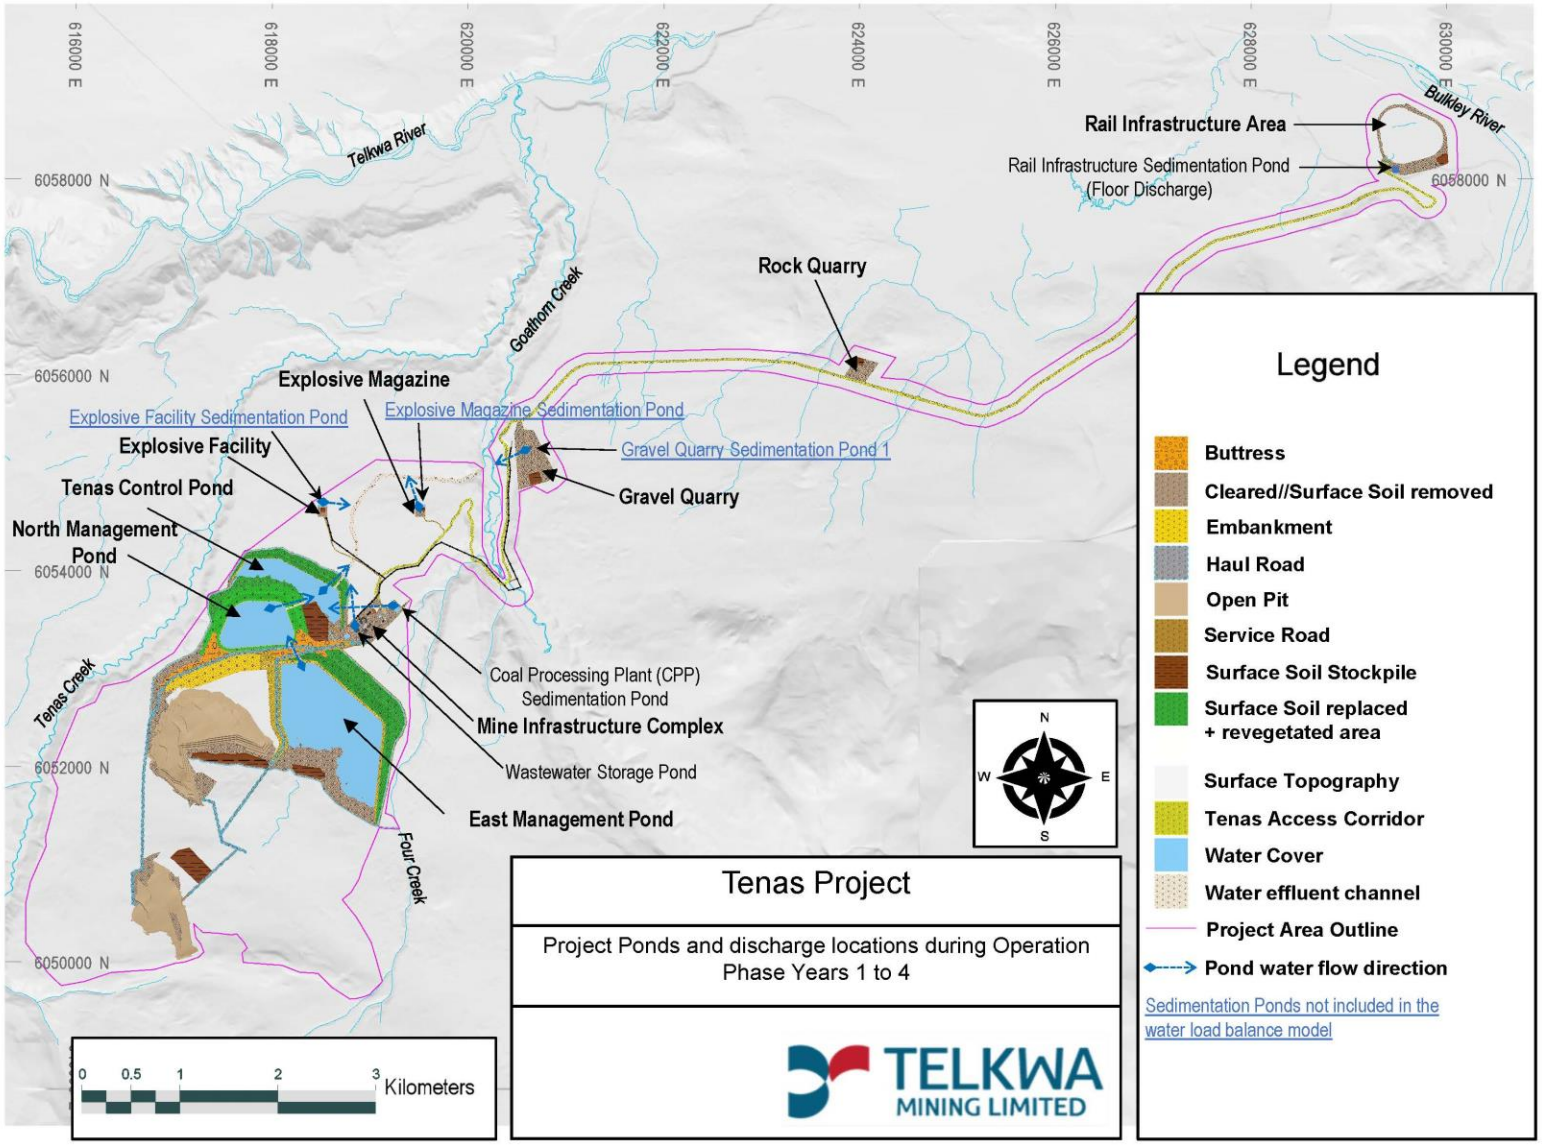

Figure 2-2: Sedimentation Ponds Location and Operation During Operation Phase Years 1 to 4 not Included in WLBM

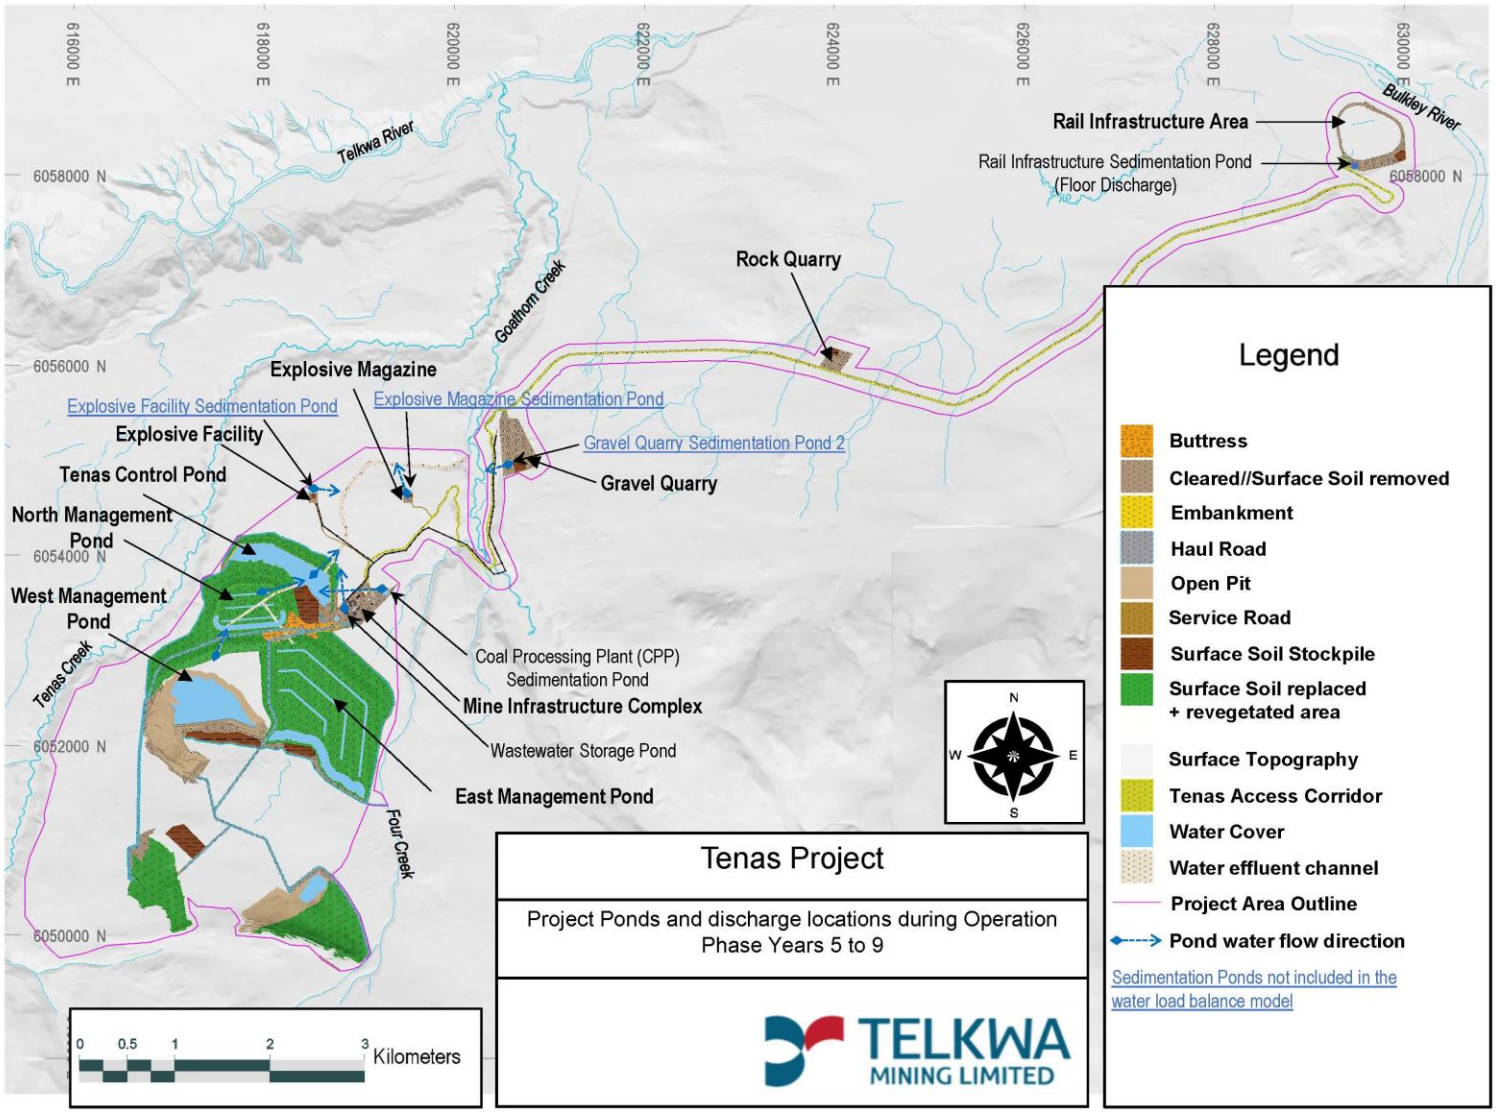

Figure 2-3: Sedimentation Ponds Location and Operation During Operation Phase Years 5 to 9 not Included in WLBM

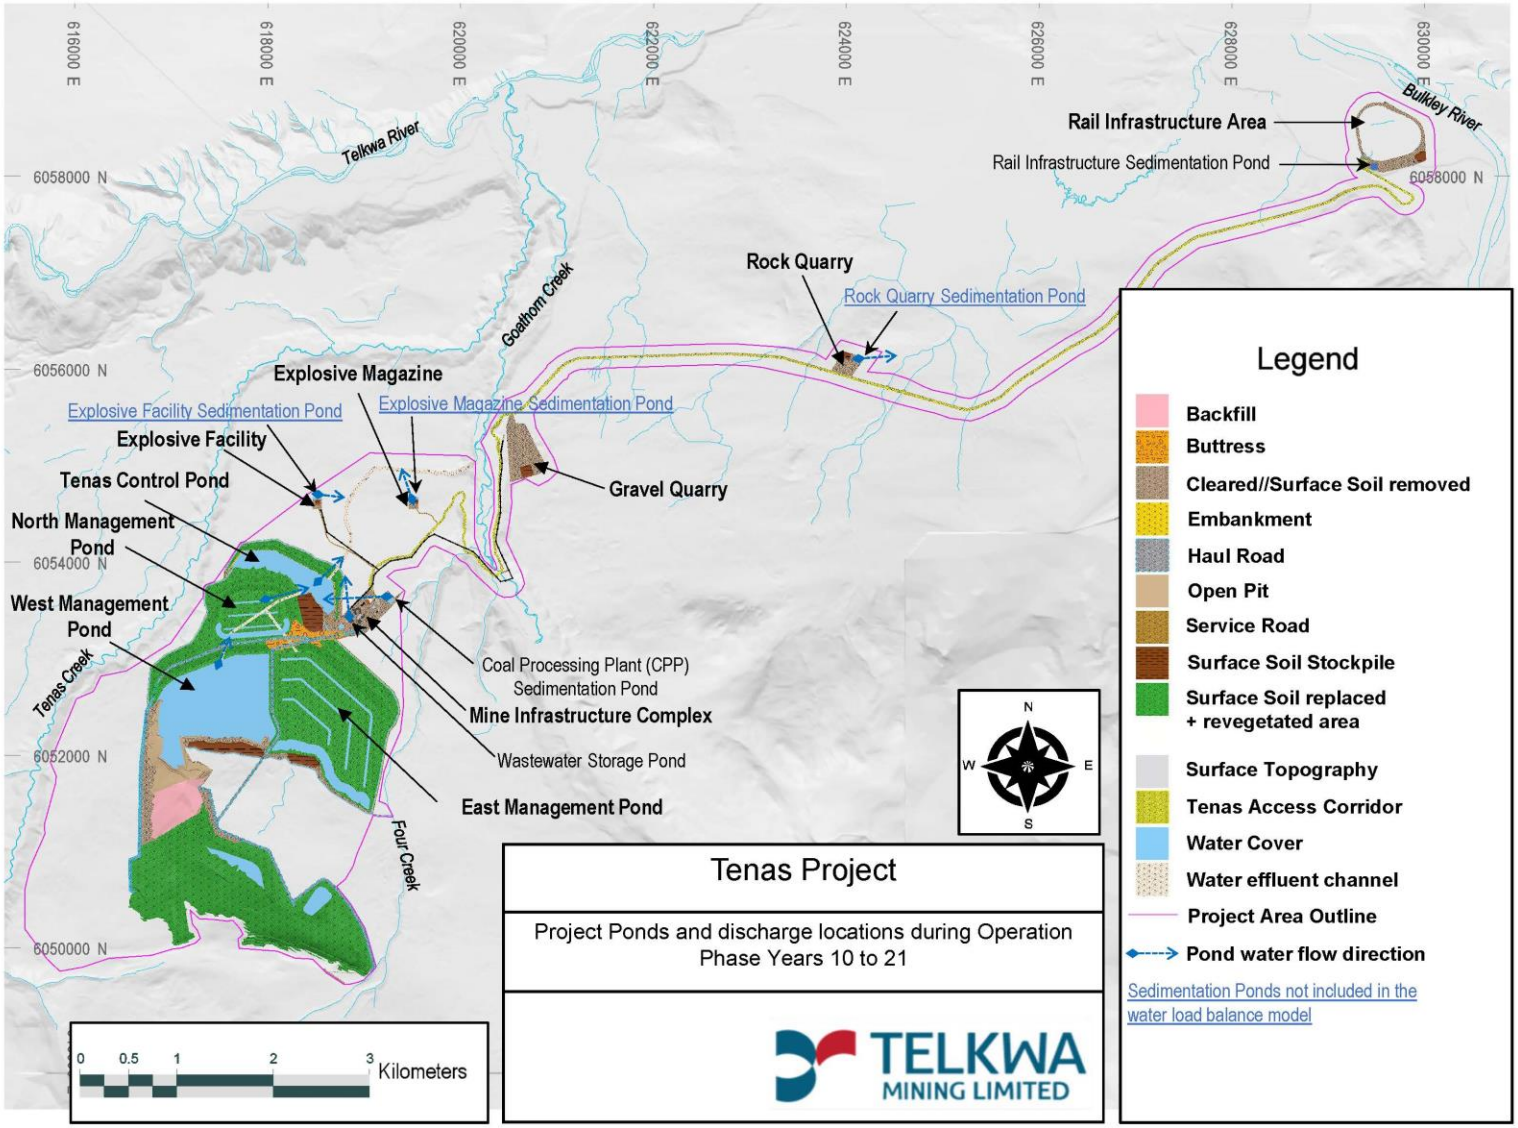

Figure 2-4: Sedimentation Ponds Location and Operation During Operation Phase Years 10 to 21 not Included in WLBM

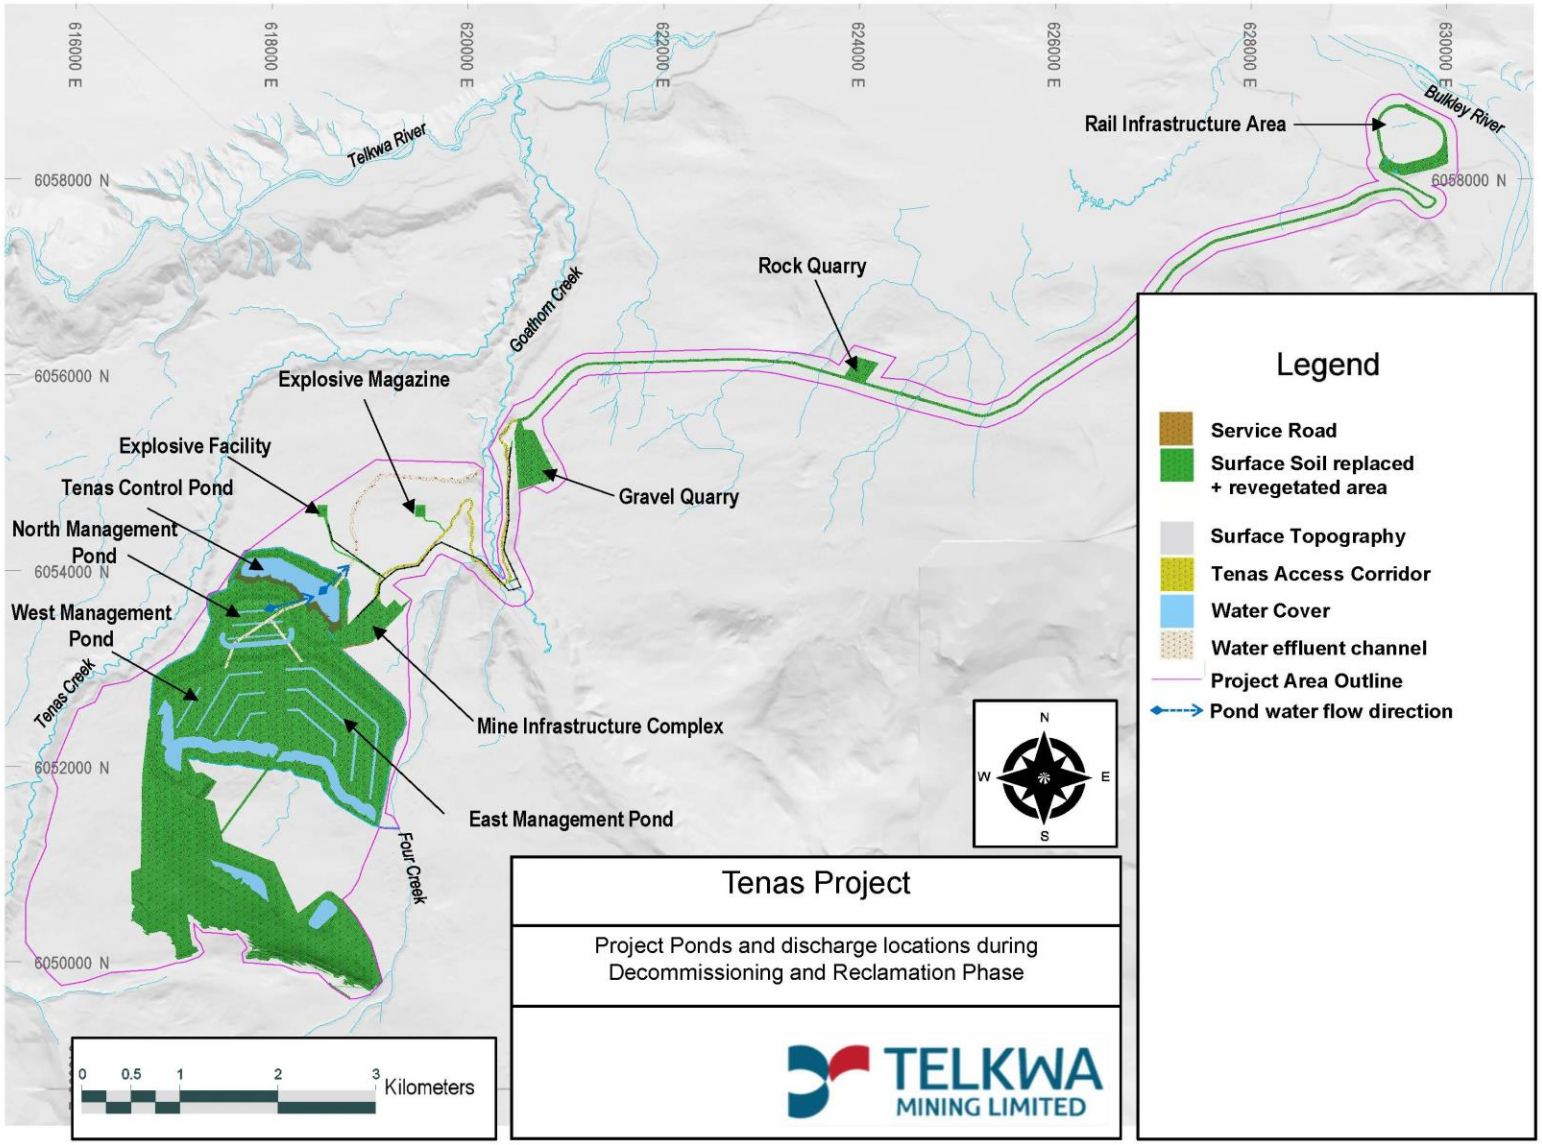

Figure 2-5: Sedimentation Ponds Location and Operation During Decommissioning & Reclamation Phase not Included in WLBM

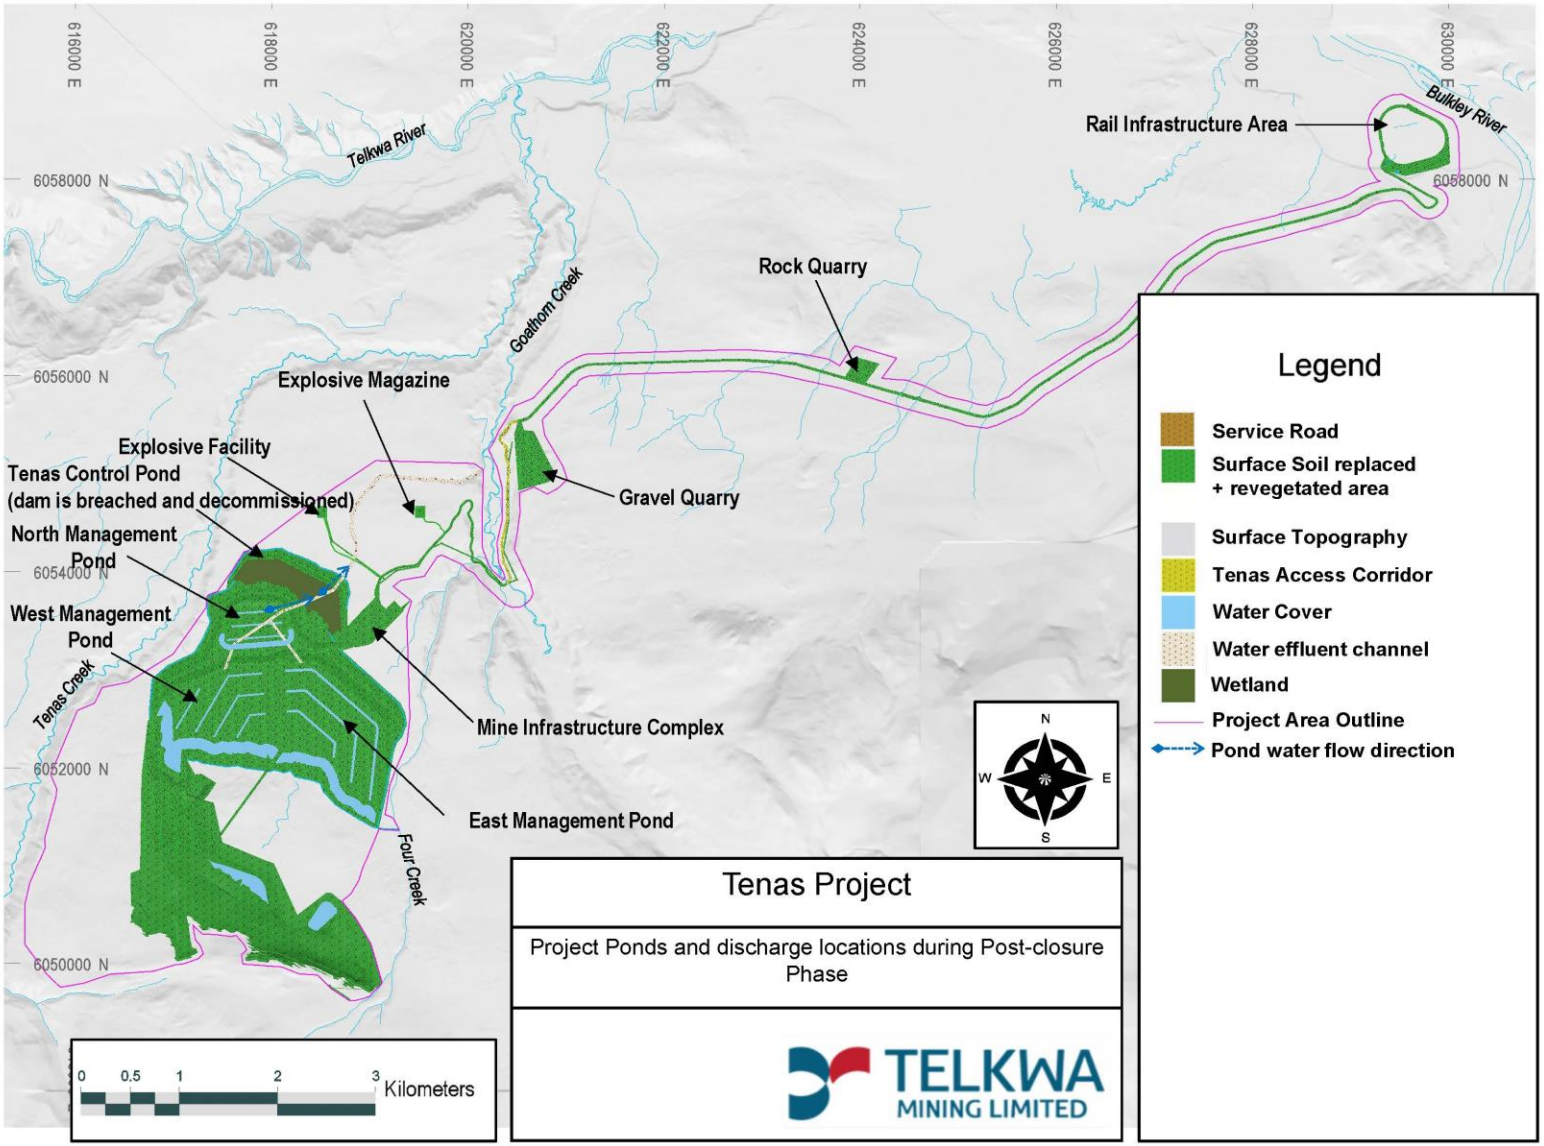

Figure 2-6: Sedimentation Ponds Location and Operation During Post closure Phase not Included in WLBM

Based on the above information the sedimentation ponds identified that the:

- Explosive Facility;
- Explosive Magazine;
- Rock Quarry;
- Gravel Quarry 1 and 2; and,
- East and West TAC

were not included in the overall WLBM completed by SRK for the EAC Application for the Project as including them would have no effect on the water quality and quantity modelled values presented for the prediction nodes nor on the subsequent effects assessments conducted for Surface Water Valued Component.

Please find attached **Appendix 6: Tenas Project Information Request Responses Related to Surface Water Valued Component, SRK** which is a technical memo addressing the IR questions posed by the BC Ministry of Environment (ENV) about the WLBM.

The following discharges have been accounted for in the WLBM:

- Tenas Control Pond;
- CPP Sedimentation Pond;
- Rail Infrastructure Sedimentation Pond;
- Potable Water Storage Pond; and,
- Wastewater Storage Pond.

The Tenas Control Pond is described in **subsections 1.9 Existing Infrastructure and Project Phases**, **1.10 Project Component Summary**, **1.16 Mine Infrastructure Complex (MIC)**, and **1.17 Water Management** in **1.0 Overview of Project Proponent Description** of the **EAC Application**. This pond is the main sedimentation pond for the Project and where mine impacted water is released during the open water season via a surface water discharge into an improved upon natural ephemeral water channel to prevent erosion and sediment release that leads into Goathorn Creek.

The CPP Sedimentation Pond is described in **subsections 1.9 Existing Infrastructure and Project Phases**, **1.10 Project Component Summary**, **1.16 Mine Infrastructure Complex (MIC)**, and **1.17 Water Management** in **1.0 Overview of Project Proponent Description** of the **EAC Application**. The EAC Application has water from the CPP Sedimentation Pond being pumped to the Tenas Control Pond and therefore this pond is not uniquely characterized but is combined with the discharge/seepage quality planned for the Tenas Control Pond. The CPP Sedimentation Pond is lined with a bituminous or alternate lining system. The CPP Sedimentation Pond will have a primary pumping system for pumping flows and a complete duplicate system to provide the

necessary redundancy for any potential pump failures. Furthermore, there will be a spare pump for each one of these systems in case of a pump failure and a backup diesel generator to run these pumps in case of grid power outages.

The discharge from the Wastewater Storage Pond is assessed as part of the overall surface flow discharge from the Tenas Control Pond. The Wastewater Storage Pond is lined with a bituminous or alternate lining system. The discharge from this pond will be via a pumped system to ensure a blending target ratio of 10 to 1 is maintained between flow from the Wastewater Storage Pond and the Tenas Control Pond. This pond has been sized to store a full year of treated wastewater from the sewage treatment plant.

The discharge from the Potable Water Storage Pond is non-contact water from water that is collected by the C02 Channel above the East Management Pond and EA Open Pit and directs this water to Four Creek or to the Potable Water Treatment Plant.

FOLLOWUP COMMENTS

FOLLOW UP 302 ITT TABLE

The discharge of effluent from sedimentation ponds for overland flow to downstream watercourses does not follow best management practices. Erosion resulting from the discharge has the potential to increase the primary POPC (TSS) to receiving waters. The cumulative effects of these additional discharges to the receiving environment have not been accounted for the IDZ study and need to be quantified. Will any mine contact water be directed to the sedimentation ponds [Clarification]?"

RESPONSE FOLLOW UP 302 ITT TABLE

Please find attached **Appendix 6: Tenas Project Information Request Responses Related to Surface Water Valued Component, SRK** which is a technical memo addressing the IR questions posed by ENV about the WLBM.

FOLLOWUP COMMENTS

508 ITT TABLE

This conceptual design brief and budgetary estimate does not state the effluent quality or discharge rate to the receiving environment. Please provide this information in a QP certified memo. If the sediment pond to which the effluent will be collected is not lined, please provide the infiltration rate. [Permitting Information Requirement]

RESPONSE 508 ITT TABLE

The Sewage Treatment Plant proposed is a secondary stage treatment plant and is targeting the following average monthly maximum discharge parameters in milligrams per litre (mg/L) at a maximum rate of 5,400 m^3 per year:

- 43 mg/L Nitrate, as nitrogen;
- 0.10 mg/L Nitrite, as nitrogen;
- 2.0 mg/L Ammonia, as nitrogen;
- 20 mg/L Biochemical Oxygen Demand (BOD); and,

- 20 mg/L TSS.

The Sewage Treatment Plant has been designed to allow it to be upgraded to a tertiary style plant in the future if discharge requirements change. The wastewater storage pond where the effluent will be collected from the Sewage Treatment Plant is lined with a bituminous liner or equivalent as is the channel transporting this wastewater to the overall mine discharge channel from the Tenas Control Pond at which point this wastewater is mixed with discharge from the Tenas Control Pond. The wastewater pond has been designed to store a complete year of effluent to provide adequate time for controlled releases from the Wastewater Storage Pond to get an adequate mixing target of approximately 10 to 1 in Goathorn Creek. Please see the attached report from Radloff Engineering and Bionest on the wastewater system in **Appendix 7: Water and Wastewater Treatment Design Report and BioNest Assurance Letter, Radloff**.

Telkwa Mining believes the details above address the requirements set forth in IR **Theme 5**.

THEME 2: SUBSTANTIALLY REVIEW THE WATER BALANCE MODEL. THE WATER BALANCE MODEL IS KEY TO ASSESSING MITIGATION AGAINST EFFECTS TO MANY VALUED COMPONENTS NOT ONLY WATER QUALITY

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

Model input values and resulting predictions for the same management structures are inconsistent between the WLBM and the Groundwater model.

509 ITT TABLE

Table 3-16 and Table 3-17 present groundwater connections to mining facilities throughout the life of mine for the expected case and high case. There are some notable differences between these tables and the corresponding tables in Appendix 4.4-A (Tables 6-6, 6-7 and 6-11). For example, the WBM does not appear to consider any groundwater connection to the NMP, while the Groundwater Model predicts seepage from the NMP throughout the life of mine. In other instances, the results appear to be different between the version of the groundwater model used in the WBM and the model presented in the application. For instance, the expected seepage rate from the WMP in Post Closure is 720 m3/d in Appendix 4.4-A while the prediction is 610 m3/d in Appendix 4.3-A. This could increase the predicted post-closure exceedances of selenium at WQS04 as both the NMP and WMP contribute to loadings at this location (based on Table 3-20 in Appendix 4.3-A). Conversely, predicted seepage from EMP in post-closure under the expected case are lower in the Appendix 4.4-A than in Appendix 4.3-A (277 m3/d vs 395 m3/d, respectively) which would reduced to the loading to the receiving environment through groundwater pathways, but may impact the expected surface discharge from the EMP, routed through the NMP and into Goathorn Creek. Please provide water balance and water quality results using inputs from the Groundwater Model provided as part of the application. [EA Information Requirement, QP Response Required].

IR LETTER NEW AND 517 ITT TABLE

There are several inconsistencies in values between Table 3-16 and Table 3-17 and the corresponding groundwater tables in Appendix 4.4-A (Tables 6-6, 6-7 and 6-11) which have provided contradictory information and predictions related to seepage throughout the life of mine, specifically related to selenium loading.

- *Have a QP provide water balance and water quality results using inputs from the Groundwater Model provided as part of the Application.*

RESPONSE 517 AND 509 ITT TABLE

Please find attached **Appendix 6: Tenas Project Information Request Responses Related to Surface Water Valued Component, SRK** which is a technical memo addressing the IR questions posed by ENV about the WLBM and **Appendix 8: Tenas Project, Hydrogeology Technical Report, SRK**.

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

Significant uncertainty remains in WLBM calibration, preventing a scientifically defensible effects assessment.

510 ITT TABLE

Section 3.1.2 describes the stochastic model used in Alternative Case 6, but this section does not demonstrate that the stochastic model adequately reproduces the temperature and precipitation variation defined in the baseline characterization (Appendix 1-R).

a) *Please provide plots and tables showing the selected stochastic model parameters produce temperature and precipitation distributions that are representative of the baseline characterization.*

b) *Please provide a rationale to demonstrate 100 model realizations are sufficient to describe climate variability and indicate the range of return periods modeled by this set of realizations. [EA Information Requirement, QP Response Required]*

IR LETTER NEW AND 518 ITT TABLE

Section 3.1.2 describes the stochastic model used in Alternative Case 6, but this section does not demonstrate that the stochastic model adequately reproduces the temperature and precipitation variation defined in the baseline characterization (Appendix 1-R).

1. *Have a QP provide plots and tables showing the selected stochastic model parameters produce temperature and precipitation distributions that are representative of the baseline characterization.*
2. *Have a QP provide a rationale to demonstrate 100 model realizations are sufficient to describe climate variability and indicate the range of return periods modeled by this set of realizations.*

RESPONSE 518 and 510 ITT TABLE

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

Significant uncertainty remains in WLBM calibration, preventing a scientifically defensible effects assessment.

511 ITT TABLE

Please provide or indicate where in the application I can find, annual water balance tables for major mine facilities (Open Pit, EMP, NMP, WMP, Tenas Control Pond) quantifying all modeled inflows, outflows and storage for Operations and Post Closure under a range of climate conditions (average, wet and dry). [EA Information Requirement, QP Response Required]

IR LETTER NEW AND 519 ITT TABLE

Have a QP provide annual water balance tables for major mine facilities (Open Pit, East, West and North Management Ponds, Tenas Control Pond) quantifying all modeled inflows, outflows and storage for Operations and Post Closure under a range of climate conditions (e.g., average, wet and dry).

RESPONSE 511 and 519 ITT TABLE

Please find attached **Appendix 6: Tenas Project Information Request Responses Related to Surface Water Valued Component, SRK** which is a technical memo addressing the IR questions posed by ENV about the WLBM.

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

Model nodes need to be appropriately located near planned discharge locations rather than many kilometers downstream.

IR LETTER NEW AND 515 ITT TABLE

a) Have a QP add additional model nodes to represent conditions at:

- *Tributary receiving discharge above confluence with Goathorn Creek.*
- *Goathorn Creek below confluence with tributary receiving discharge.*

Have a QP provide water quantity and quality results for these nodes over the life of mine for the following assessment cases:

- *Project Case*
- *Alternative Case 1, 2, 3, 4 and 5*

Have a QP provide water quality results in figures and table with comparison to relevant water quality guidelines, as provided in Appendix 6 & G of Appendix 4.3-A of the application.

IR LETTER OVERVIEW

Seasonal and monthly variability of background water quality concentrations may affect predicted water quality parameter concentrations.

IR LETTER NEW AND 515 ITT TABLE

b) Have a QP clarify if the background water quality inputs used in the model were annual median values or if monthly (or seasonal) median values were used (section 3.10.1 of Appendix 04.3-A, the Water & Load Balance Modeling Report). If monthly or seasonal background concentrations were used, please provide a table describing their values and ranges. If monthly or seasonal median values were not used, have a QP re-run the Project Assessment Case and Alternative Assessment Case 5 (see Table 2-3 in Appendix 04.3-A) to generate water quality predictions using either monthly (or seasonal) median background values or the annual 95th percentile of background; present results in a format similar to Appendix 6 of Appendix 04.3-A.

RESPONSE 515 ITT TABLE

The following prediction node have been added to the WLBM:

- WQEA1 which represents Goathorn Creek below confluence with tributary receiving discharge; and,
- A prediction node was not added for the tributary receiving discharge above confluence with Goathorn Creek as its quality has been assumed to be same as the end of pipe discharge due to the lack of water in this tributary.

Please find attached **Appendix 6: Tenas Project Information Request Responses Related to Surface Water Valued Component, SRK** which is a technical memo addressing the IR questions posed by ENV about the WLBM. In summary the background water quality inputs used in the EAC Project Case (August 2022) WLBM were monthly mean values while seasonal values are used in both the Updated and Final EAC Project Cases (2024).

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

Significant uncertainty remains in WLBM calibration, preventing a scientifically defensible effects assessment.

FOLLOW UP 293 ITT TABLE

"Thank you for the response. I note that the derived synthetic and measured site precipitation appear correlated, as demonstrated in the slides; however, the monthly linear relationships (pg 14) do not demonstrate a relationship approaching 1:1, which would indicate the synthetic approximates the measured data.

- *a) To clarify, were these monthly relationships used to further adjust the derived synthetic record to improve the fit to the measured data? [Clarification, QP response required]*
- *b) Please provide a figure showing concurrent cumulative precipitation records (i.e., double mass curve) and a table with monthly and annual precipitation from both the measured record and final derived/synthetic record(s) that was:*
  - *i. used as input to the water balance model, and*
  - *ii. used to characterize site precipitation and estimate extreme precipitation. If separate records were used, please present both. [EA information requirement, QP response required]"*

IR LETTER NEW AND NEW 293 ITT TABLE

Monthly linear relationships do not demonstrate a relationship approaching 1:1 which would indicate the synthetic approximates the measured data.

1. *Have a QP clarify if monthly relationships were used to further adjust the derived synthetic record to improve the fit to the measured data;*
2. *Have a QP provide a figure showing concurrent cumulative precipitation records (i.e., double mass curve) and a table with monthly and annual precipitation from both the measured record and final derived/synthetic record(s) that was:*

a. *used as input to the WLBM; and used to characterize site precipitation and estimate extreme precipitation (if separate records were used, present both).*

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

Significant uncertainty remains in WLBM calibration, preventing a scientifically defensible effects assessment.

FOLLOW UP 294 ITT TABLE

Thank you for the response. I'm struggling to understand why this linear regression (Figure 4-16) was selected by the QP as appropriate for this analysis, given the issues described in the response. Without being able to attribute the difference unit runoff/discharge from these similarly located stations to a physical attribute or rationalize an incremental unit runoff of roughly 80 l/s/km2 for the area between these stations, using a 0.8 or 0.85 ratio to scale the historic Goathorn WSC record to the site station represents flawed logic, in my opinion. In particular, the high flow regression is driven, in large part, by the extrapolated high flow section of the site rating curve, where the curve is not supported by stage-discharge measurements.

As Goathorn Creek is the receiving environment for surface discharge from the proposed project and seepage from the management ponds in Post-Closure, the selected regression could have a notable impact on water quality predictions in the receiving environment, thus introducing considerable uncertainty into the assessment of impacts from the proposed project. I understand that this synthetic record was used, in part, to calibrate the rainfall-runoff model used in the water balance model. Using an updated regression (scale by drainage area or refined with

published data), please describe, and quantify the bias that was introduced into the baseline characterization, model calibration and results and impact assessment by the selected regression. Please consider comments ID 295 and 296 in your response. [EA information requirement, QP response required]

294 IR LETTER

Given the minor difference in drainage area between Goathorn-Hydro and Goathorn (08EE008) (1% difference), the selected linear regression (Fig 4-16) describes a surprisingly large difference in unit discharge.
Have a QP use an updated regression (scale by drainage area or refined with published data) to describe and quantify the bias that was introduced into the baseline characterization, model calibration, and results and impact assessment by the selected regression.

RESPONSE 294 IR LETTER AND FOLLOW UP 294 ITT TABLE

Please find attached **Appendix 6: Tenas Project Information Request Responses Related to Surface Water Valued Component, SRK** which is a technical memo addressing the IR questions posed by ENV about the WLBM.

INITIAL COMMENTS

295 ITT TABLE

Please provide figures showing mean monthly measured and rainfall-runoff modelled streamflow for Tenas-Hydro, Goathorn-Hydro, and Telkwa-Hydro. It is hard to see the match of hydrograph shape and amplitude at moderate and low flows from the figures provided. As results from the GoldSim model are presented monthly, I am also interested in the visual match at a monthly timestep, over the daily timestep provided. [Information Request]

RESPONSE 295 ITT TABLE

See Attachment #295-1 for mean monthly streamflow from measured and modelled datasets. For measured streamflow, monthly average values were only calculated for months missing less than 5 days of data.

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

Significant uncertainty remains in WLBM calibration, preventing a scientifically defensible effects assessment.

FOLLOW UP 295 ITT TABLE

Thank you for the plots. It appears the rainfall-runoff model underpredicts the freshet, particular in 2018, and typically predicts that the freshet peaks in June, rather than in April or May as shown in the measured record. In addition, the model appears to be underpredicting summer low flows, with the exception of 2018 at Tenas-Hydro only. As this model was used in the water balance model to predict runoff for unimpacted watersheds as well as reclaimed mine impacted areas, this calibration introduces considerable uncertainty into the water management and water quality predictions. In your response to the following questions, please consider comments ID 294 and 296.

a) *What sensitivity analysis was completed on this model calibration? Were other rainfall-runoff model frameworks attempted and shown to be worse? In particular, I'm interested to know if a model with a more dynamic infiltration/runoff component was considered given the model application.*

b) *If the model were better calibrated to freshet conditions, please describe, and quantify the impact this would have on predicted surface discharge quantity and quality over the life of mine and over a range of climatic conditions?*

c) *If the model were better calibrated to summer low flow conditions, please describe, and quantify the impact this model improvement would have on predicted water quality in the receiving environment during low flow periods over the life of mine over a range of climatic conditions.*

d) *What data collection efforts are underway to support refining/recalibrating/redeveloping this model?*

e) *Why was this calibration considered sufficient for impact assessment? I note the QP has "strongly suggested that this study be revisited and that the model be recalibrated when longer ... records are available... and when all WSC flow data are published".*

RESPONSE FOLLOW UP 295 ITT TABLE

Please find attached **Appendix 6: Tenas Project Information Request Responses Related to Surface Water Valued Component, SRK** which is a technical memo addressing the IR questions posed by ENV about the WLBM.

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

Significant uncertainty remains in WLBM calibration, preventing a scientifically defensible effects assessment.

FOLLOW UP IR LETTER 295/296 AND 295 ITT TABLE

The rainfall – runoff model, used in the WLBM to predict runoff from unimpacted and reclaimed watersheds, appears to underpredict the median and range of flow conditions by a sizeable margin in Goathorn Creek, Tenas Creek and Telkwa River when compared to the synthetic records. The rainfall-runoff model also appears to poorly match the hydrograph shape, specifically the magnitude and timing of the freshet and the summer low flows when compared to the measured record. This poor calibration introduces considerable uncertainty into the water management and water quality predictions based on the WLBM results.

- *Have a QP provide a robust demonstration that the model is sufficiently calibrated to available measured and synthetic datasets with a focus on common flow conditions (the annual range of average flow conditions). Where modeled results deviate considerably from baseline characterization, describe and quantity the impact to predicted surface discharge quantity and quality, and predicted water quality in the receiving environment over the life of mine and for the applicable assessment cases caused by model bias.*

  OR

- *Have a QP recalibrate the rainfall-runoff model to provide the evidence outlined above. Describe the impact on surface water discharge quantity and quality, water management (waste management pond water levels), and receiving environment water quality over the life of mine. Provide revised results in a format consistent with Appendix 6 and G Appendix 4.3-A of the application for all assessment cases.*

RESPONSE FOLLOW UP 295 ITT TABLE

Please find attached **Appendix 6: Tenas Project Information Request Responses Related to Surface Water Valued Component, SRK** which is a technical memo addressing the IR questions posed by ENV about the WLBM.

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

Significant uncertainty remains in WLBM calibration, preventing a scientifically defensible effects assessment.

FOLLOW UP IR LETTER 295/296 AND 296 ITT TABLE

Thank you for the plots. It appears the rainfall-runoff model underpredicts the median and range of flow conditions by a sizeable margin in Goathorn Creek, Tenas Creek and Telkwa River when compared to the synthetic records. The flows at the 50% probability of exceedance in Telkwa River appear to be underestimated by over 10 m3/s and the estimated mean annual discharge (MAD) at this location is 27.3 m3/s (Table 4-24). Based on the provided flow duration curve (FDC) figure in the response, MAD has a 70% probability of exceedance using the synthetic record while the modelled record gives MAD a 45% probability of exceedance. Similarly, for Tenas Creek, at the 50% probability of exceedance, the modelled record is roughly 0.1 m3/s lower than the synthetic record, and the estimated MAD at this location is 0.5 m3/s. Based on the FDC for Tenas, MAD has a 26% probability of exceedance using the synthetic record, and the difference between the synthetic and modeled is roughly 0.15 m3/s, indicating the MAD is modeled roughly a third lower than the synthetic record suggests. At Goathorn Creek, the modeled record underpredicts the synthetic, which is likely also underestimated (see ID 294).

a) Why was this calibration considered sufficient for impact assessment?

b) Please calibrate the model to the bulk of flow conditions and describe and quantify the impact on surface water discharge quantity and quality, water management (waste management pond water levels), and receiving environment water quality over a range a flow conditions over the life of mine.

[EA information requirement, QP response required]

RESPONSE FOLLOW UP 296 ITT TABLE

Please find attached **Appendix 6: Tenas Project Information Request Responses Related to Surface Water Valued Component, SRK** which is a technical memo addressing the IR questions posed by ENV about the WLBM.

Telkwa Mining believes **Appendix 6: Tenas Project Information Request Responses Related to Surface Water Valued Component, SRK** with the answers provided above addresses the requirements set forth in IR **Theme 2**.

THEME 1: DESIGN ALTERNATIVE TREATMENT OPTIONS WHICH ARE CAPABLE OF MEETING WATER QUALITY GUIDELINES (WQGS) NEAR APPROPRIATELY SITED DISCHARGE LOCATIONS

FOLLOWUP COMMENTS

175 ITT TABLE

EMLI is consulting with ENV on water quality monitoring and water management measures for this project. Telkwa Coal will need to propose conceptual design of management structures as part of the current application to demonstrate that the Project as proposed is capable of managing water not suitable for discharge and meeting WQGs.

176a ITT TABLE

EMLI understands that ENV's review of the surface water quality effects assessment and proposed water quality benchmarks is ongoing. EMLI notes that based on that review additional water quality mitigation for the Project may be required. Should water treatment or other mitigation measures be proposed for the Project, EMLI will review the information at that time. Telkwa Coal is encouraged to engage as soon as possible with EMLI on any proposed water treatment, especially if any passive or semi-passive technologies are proposed.

RESPONSE 176a ITT TABLE

Telkwa Mining understands if water treatment becomes a requirement that EMLI will need to be engaged with these technologies, whether they are passive, semi-passive or active. Telkwa Mining has started engagement with EMLI as of Q3, 2024.

LETTER IR 176 AND 176b ITT TABLE

1. *Provide conceptual design of alternative treatment options, mitigation measures, and management structures that can manage water not suitable for discharge and that meet BC WQGs.*

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

The Water and Load Balance Model (WLBM) is key to assessing the effectiveness of mitigation against effects to many VCs, including water quality.

- *Source control and mitigation or treatment options included in the WLBM do not demonstrate that Water Quality Guidelines (WQG) will be met near discharge locations and will lead to exceedance of WQGs over many kilometres of multiple watercourses.*

FOLLOW UP IR LETTER NEW AND 514 ITT TABLE

Provide design alternative treatment options which are capable of meeting WQGs near appropriately sited discharge locations. Describe the reliability, control-effectiveness, and treatment efficiency of each mitigation option including the currently proposed option – refer to BC ENV Best Achievable Technology (BAT) guidance. BAT assessments are required prior to the development of Initial Dilution Zones (IDZs) – also refer to BC IDZ development guidance.
When considering discharge standards, follow these best practices and minimum standards:

a) *The discharge must not be acutely toxic.*

Telkwa Mining completed a two-step process to determine if the discharges are potentially acutely toxic as follows:

1. A review was conducted of the end of pipe discharge concentrations versus the relevant BC Water Quality Acute Guidelines with any parameter having a concentration less than these guidelines not being acutely toxic; and,
2. For the few parameters that had end of pipe concentrations higher than the BC Water Quality Acute Guidelines, Borealis Environmental Consulting Inc was retained to review these concentrations versus the relevant acute toxicity limits for rainbow trout and Daphne Magna and determined that the modelled concentrations at end of pipe are not acutely toxic. Please see **Appendix 9: Evaluation of Acute Daphnia Magna and Rainbow Trout LC50 Toxicity Supporting Tenas Project Best Available Technology Assessment Study – Parameters of Concern: Nitrite, Iron (Total) and Iron (Dissolved)**.

Telkwa Mining commits to toxicity testing of final effluent discharges utilizing the methodology provided by BC government via Section F Toxicity Test Methods (https://www2.gov.bc.ca/assets/gov/environment/research-monitoring-and-reporting/monitoring/emre/manuals/environmental-lab-manual/2023-09-18-bc-elm-2022-section-f.pdf).

b) If the untreated effluent contains constituents that exceed 80% of an applicable WQG, BMPs and BAT must be applied. Chronic WQG for the protection of freshwater aquatic life are most typically used as the guideline. However, if more sensitive uses or values are downstream (e.g., drinking water, irrigation, livestock, wildlife) the most protective WQG will be applied.

c) If the effluent still does not meet WQGs, repeat step (b). Document this iterative process.

d) If the effluent still does not meet WQGs after all reasonable BMPs and BAT are applied, an IDZ may be considered during the permitting process. Some chronic toxicity may be tolerated in the IDZ, but water quality should meet WQGs at the end of the IDZ. An IDZ will not be considered during permitting without an adequate BAT assessment.

e) If the water quality at the end of the IDZ still exceeds chronic WQGs, an SPO may be considered during the permitting process. SPOs must be protective of the site-specific environment. An SPO will not be considered during permitting without an adequate BAT assessment.

514 ITT TABLE

Within the bounds of the above best practices and minimum standards, the proponent, and their qualified professionals (QPs) are normally best suited to consider which site-specific factors should be evaluated regarding feasibility, reliability, control effectiveness, and cost effectiveness. To improve efficiency, it may be useful to have a conversation with the ENV on the file once an outline for the BAT assessment has been developed. In practice, the depth and detail of the BAT assessment submittal will be proportionate to the projected effluent quality. If the selected BAT will achieve BC WQGs at the point of discharge, the submittal can be brief and will likely be readily advanced. If the selected BAT is not capable of meeting BC WQGs in the receiving environment, the submittal must be more substantial and will be subjected to a more intensive review, as it must justify the greater risk to the environment.

Some of the technologies TCL has proposed to consider during the BAT assessment are likely to be effective mitigation measures for the Tenas project. TCL may need to consider a set (a series or train) of technologies to address all contaminants of concern. During an EA process, technologies must be at a readiness level of 7 to be considered as primary mitigation. At permitting, technologies must be at a readiness level of 8 or 9 to be considered as primary mitigation. ENV and EMLI consider some of the proposed technologies to be below the appropriate technology

readiness level (TRL) for the Tenas project. The proponent may conduct a Technology Readiness Assessment (TRA) (refer to technical guidance 21 on the Mining and Smelting Guidance webpage) for consideration by ENV and EMLI to demonstrate the technological readiness of any proposed technology. TCL is encouraged to engage with ENV and EMLI prior to undertaking a TRA.

FOLLOW UP 353 ITT AND 355 ITT TABLE

As a result of the BAT conducted for waste rock and tailings management, the selected strategy (subaqueous storage) will provide a good degree of source control in terms of ML/ARD rate, thereby improving effluent quality. However, a BAT assessment is also required to consider appropriate strategies for the management of mine effluent that will be discharged to the environment.

Discharges to ground and non-point source discharges to the environment must be assessed in addition to discharges to surface water. Standard thresholds for discharges to ground are outlined in the ENV guidance document, which is located here: https://www2.gov.bc.ca/assets/gov/environment/waste-management/industrial-waste/industrial-waste/mining-smelt-energy/guidance-documents/7276_env_rob_dtg_factsheet.pdf

The water quality model predicts that, due to a slowly advancing groundwater plume, the project will result in WQG exceedances in Four and Tenas Creeks. Although these impacts may not occur until after the target coal has been extracted, they are predicted to persist for generations.

The response to the initial comment includes an explanation that assumes an Initial Dilution Zone (IDZ). Similar to the SPOs, an IDZ will not be assessed or authorized unless a BAT assessment is first conducted (following the ENV guidance document). Following BAT, these considerations (SPOs and IDZ) can be assessed through the permitting process under the Environmental Management Act but are not appropriate for inclusion in this review under the Environmental Assessment Act. [Permitting Information Requirement]

IR LETTER OVERVIEW

Reviewers have identified that the current Application shows potential for significant adverse effects to water quality and aquatic biota as there is insufficient water quality mitigation measures to protect the receiving environment.

- *The predicted water quality and the approach to use a few small watercourses as effluent conveyance will result in residual effects to aquatic valued components (VCs) that cannot be reliably managed in BC Environmental Management Act permitting.*

Alternative treatment options capable of meeting WQGs at appropriately sited discharge locations are missing from the Application.

Additional conceptual design of alternative treatment options, mitigation measures, and management structures are needed to prevent the discharge of water that is not suitable for release to the environment.

IR LETTER OVERVIEW

The Water and Load Balance Model (WLBM) is key to assessing the effectiveness of mitigation against effects to many VCs, including water quality.

- *Source control and mitigation or treatment options included in the WLBM do not demonstrate that Water Quality Guidelines (WQG) will be met near discharge locations and will lead to exceedance of WQGs over many kilometres of multiple watercourses.*

LETTER IR 350 AND 350 ITT TABLE

Provide additional mitigation measures to address the significant exceedance of WQGs in frequency and duration for selenium, nitrite, sulphate and dissolved cadmium in Four Creek and Tenas Creek.

RESPONSE IR 175, 176b, 514, 350, 353, and 355

Final EAC Project Case (2024) Development

Telkwa Mining considered incorporating multiple additional mitigation controls in developing the Final EAC Project Case (2024) consisting of the following additional mitigation controls/best management practices (BMP) and/or technologies:

- Management and Control Pond liner design modifications (technology);
- Additional use of water by the CPP (BMP);
- Blasthole Liners (BMP);
- Passive/Active Flocculation(technology);
- Storage and Use of Freshet Water (BMP);
- Water treatment for surface water flows (technology); and
- Water treatment of seepage flows (technology).

The Final EAC Project Case (2024) does not have exceedances in the receiving environment except for parameters that are already in exceedance for background/baseline conditions and a short duration (4 year) exceedance of cobalt in Four Creek which is likely not to occur if attenuation mechanisms in groundwater were accounted for in the water model.

The following sections provide a description of each additional mitigation control/technology and modelled parameter concentrations compared to the Updated EAC Project Case (2024). Please see **Appendix 10: Effect of Mitigation Controls on Water Quality and Quantity of the Tenas Project, SRK.**

Management and Control Pond Liner Modifications (technology)

Table 2-2 provides a summary of the liner systems presented in the EAC Application. These liners were incorporated into the various management and control ponds for the control of seepage from these structures primarily towards the downstream watercourses of Tenas, Four, and Goathorn Creeks.

Table 2-2: Environmental Assessment Certificate (EAC) Liner Designs

Location	Liner Type	Details
Tenas Control Pond	Bituminous	A bituminous liner installed on compacted existing overburden

Location	Liner Type	Details
North Management Pond (floor, embankment face)	Soil-Bentonite	30-centimetre (cm)-thick soil bentonite liner that is blended into existing overburden and compacted and then followed by a 16-ounce filter fabric protection layer all installed on top of compacted existing overburden
East Management Pond (floor, embankment face)	Soil-Bentonite	30-cm-thick soil bentonite liner that is blended into existing overburden and compacted and then followed by a 16-ounce filter fabric protection layer all installed on top of compacted existing overburden
West Management Pond (overburden floor, overburden in the pit and embankment face)	Soil-Bentonite	30-cm-thick soil bentonite liner that is blended into existing overburden and compacted and then followed by a 16-ounce filter fabric protection layer all installed on top of compacted existing overburden
West Management Pond (bedrock floor)	None	No liner prescribed
West Management Pond (bedrock south end EA Open Pit wall)	None	No liner prescribed

SRK completed an option analysis for Telkwa Mining on various liner modifications with the aim of reducing the potential impact of groundwater seepage to the receiving environment. **Table 2-3** provides two modified liner designs that were considered as a potential technology for BAT assessment provided in **Appendix 11: Tenas Project Best Achievable Technology Assessment Updated, SRK**.

Table 2-3: Revised Liner Designs Investigated

Location	Liner Type	Revised Liner Design Details
Tenas Control Pond	Soil-Bentonite with Bituminous Line Above	15-centimetre (cm)-thick soil bentonite liner that is blended into existing overburden and compacted and then followed by a bituminous geomembrane liner on top of this installed on compacted existing overburden.
North Management Pond (floor, embankment face)	Soil-Bentonite	56-cm-thick soil bentonite liner that is blended into existing overburden and compacted and then followed by a 30-cm thick layer of compacted overburden protection layer installed above the liner.
East Management Pond (floor, embankment face)	Soil-Bentonite with Bituminous	Option 1: 56-cm-thick soil bentonite liner that is blended into existing overburden and compacted and then followed by a 30-cm layer of compacted overburden protection layer installed above the liner. Option 2: 56-cm-thick soil bentonite liner that is blended into existing overburden and compacted and then followed by a bituminous geomembrane liner followed by

Location	Liner Type	Revised Liner Design Details
		a 30-cm layer of compacted overburden protection layer installed above the liner.
West Management Pond (overburden floor, overburden in the pit and embankment face)	Soil-Bentonite	56-cm-thick soil bentonite liner that is blended into existing overburden and compacted and then followed by a 30-cm layer of compacted overburden protection layer installed above the liner.
West Management Pond (bedrock floor)**	None**	No liner prescribed**
West Management Pond (bedrock south end wall)	None	No liner prescribed

Notes:

**There is still the possibility to introduce a soil-bentonite liner in the West Management Pond bedrock floor portions during the Operation Phase if parameters of concern are found to be higher in the North, and East Management Ponds than predicted in the EA.

The revised liners specified in **Table 2-3** above were incorporated into the groundwater model to determine seepage levels from these facilities with the revised technical report provided in **Appendix 8: Tenas Project, Hydrogeology Technical Report, SRK**. **Table 2-4** provides a summary of the changes in net seepage values achieved for the above structures.

Table 2-4: Seepage Values in m^3 per day with Revised Liner Designs at End of Mining for Options 1 and 2

CASE	WMP	NMP	EMP	TCP
Updated EAC Project Case (2024)	836	198	458	140
Option 1	373	87	277	8
Option 2	373	87	63	8

These revised seepage values were then used as inputs for the water and load balance model to look at potential mitigations compared to a base case without the use of liners. This was completed by SRK in Appendix 10: Effect of Mitigation Controls on Water Quality and Quantity of the Tenas Project, SRK with **Table 2-5** providing a summary of these results for relevant prediction nodes. Based on the information in **Table 2-5** it was decided to carry this mitigation control forward into the BAT assessment process to determine if this mitigation control is recommended to be incorporated into the Final EAC Project Case (2024).

Table 2-5: Water Quality (Maximum Monthly Mean) Results for Revised Liner Designs in Post-closure using Typical Source Terms and Average Hydrology at Relevant Prediction Nodes

Location Creek	Parameter	BC WQG (2024) (mg/L)	Updated EAC Project Case (2024) (mg/L)	Liner Option 1 (mg/L)	Liner Option 2 (mg/L)
WQSEA1 Goathorn Creek	Copper (d)	0.0013	0.0021	0.0021	0.0021
WQSO6 Goathorn Creek	Copper (d)	0.0013	0.0021	0.0021	0.0021
WQS03-DS Four Creek	Cobalt (t)	0.004	0.00068	0.00092	0.00050
	Nitrite (t)	0.020	0.015	0.0084	0.00027
	Sulphate (t)	309	33	18	6
	Selenium (t)	0.0020	0.00081	0.00045	0.00013
WQS04 Tenas Creek	Copper (d)	0.0026	0.0015	0.0015	0.0015
	Nitrite (t)	0.020	0.0090	0.0084	0.0080
	Sulfate (t)	218	24	22	20
	Selenium (t)	0.0020	0.00078	0.00072	0.00063

Notes: %=percent; BC=British Columbia; EAC=Environmental Assessment Certificate; mg/L=milligrams per litre; WQG=water quality guidelines.
Red text indicates exceedances of WQGs.
Please note that dissolved copper exceeds the WQGs under background conditions.

Additional Water Use by the CPP

The current EAC application has the CPP producing a dry (25% moisture) processed rock stream that is then hauled and placed into the management ponds. The primary reason for this was to limit water use by the Project. However, as the Project discharges water every year when in operation even during drought conditions there is an opportunity to go to a conventional wet slurry system for the processed rock stream by the CPP. This will increase the amount of water required by the CPP with the benefit of permanently tying up this water into the coarse and fine processed rock products. Water from the open pit would be used for this additional use and would improve water quality discharged by the Project. The change in water use by the CPP was incorporated into the WLBM report completed by SRK which is provided in **Appendix 10: Effect of Mitigation Controls on Water Quality and Quantity of the Tenas Project, SRK** with **Table 2-6** below providing a summary of these results for the relevant prediction nodes. Based on these

results and the increased water usage this mitigation control was not carried forward into the Final EAC Project Case (2024).

Table 2-6: Water Quality (Maximum Monthly Mean) Results for Additional Water Use by the CPP during Operation in Post-closure using Typical Source Terms and Average Hydrology at Relevant Prediction Nodes

Location Creek	Parameter	BC WQG (2024) (mg/L)	Updated EAC Project Case (2024) (mg/L)	Additional CPP Water Use (mg/L)
WQSEA1 Goathorn Creek	Copper (d)	0.0013	0.0021	0.0021
WQSO6 Goathorn Creek	Copper (d)	0.0013	0.0021	0.0021
WQS03-DS Four Creek	Cobalt (t)	0.004	0.00068	0.00069
	Nitrite (t)	0.020	0.015	0.015
	Sulphate (t)	309	33	34
	Selenium (t)	0.0020	0.00081	0.00085
WQS04 Tenas Creek	Copper (d)	0.0026	0.0015	0.0015
	Nitrite (t)	0.020	0.0090	0.0091
	Sulfate (t)	218	24	24
	Selenium (t)	0.0020	0.00078	0.00082

Notes: %=percent; BC=British Columbia; EAC=Environmental Assessment Certificate; mg/L=milligrams per litre; WQG=water quality guidelines.
Red text indicates exceedances of WQGs.
Please note that dissolved copper exceeds the WQGs under background conditions.

Blasthole Liners

Telkwa Mining has incorporated the use of blasthole liners for holes in rock requiring the addition of blasting agents into the Final EAC Project Case (2024) using a 75% effectiveness on the portion of nitrogen species being produced from blasting which is conservative compared to the actual 95% effectiveness observed at current operations in BC.

The change in nitrogen species was incorporated into the WLBM report completed by SRK which is provided in **Appendix 10: Effect of Mitigation Controls on Water Quality and Quantity of the Tenas Project, SRK**, with **Table 2-7** below providing a summary of these results for the relevant prediction nodes. Based on these results this mitigation control was incorporated into the Final EAC Project Case (2024).

Table 2-7: Water Quality (Maximum Monthly Mean) Results for Use of Blasthole Liners during Operation in Post Closure using Typical Source Terms and Average Hydrology at Relevant Prediction Nodes

Location Creek	Parameter	BC WQG (2024) (mg/L)	Updated EAC Project Case (2024) (mg/L)	Use of Blasthole Liners (mg/L)
WQSEA1 Goathorn Creek	Copper (d)	0.0013	0.0021	0.0021
WQSO6 Goathorn Creek	Copper (d)	0.0013	0.0021	0.0021
WQS03-DS Four Creek	Cobalt (t)	0.004	0.00068	0.00068
	Nitrite (t)	0.020	0.015	0.010

	Selenium (t)	0.0020	0.00081	0.00081
WQS04 Tenas Creek	Copper (d)	0.0026	0.0015	0.0015
	Nitrite (t)	0.020	0.0090	0.0060
	Sulfate (t)	218	24	24
	Selenium (t)	0.0020	0.00078	0.00078

Notes: %=percent; BC=British Columbia; EAC=Environmental Assessment Certificate; mg/L=milligrams per litre; WQG=water quality guidelines.
Red text indicates exceedances of WQGs.
Please note that dissolved copper exceeds the WQGs under background conditions.

Passive/Active Flocculation

The EAC Application had a target of producing a maximum TSS concentration for 35 mg/L discharging from sedimentation ponds. To reduce total concentrations of parameters such as Iron and Aluminium, passive and active flocculation can be added to the TCP to reduce the designed maximum TSS concentrations from 35 mg/L to 5 mg/L.

The change in TSS was incorporated into the WLBM report completed by SRK which is provided in **Appendix 10: Effect of Mitigation Controls on Water Quality and Quantity of the Tenas Project, SRK**, with **Table 2-8** below providing a summary of these results for the relevant prediction nodes. Based on the information in **Table 2-8** it was decided to carry this mitigation control forward into the BAT assessment process to determine if this mitigation control is recommended to be incorporated into the Final EAC Project Case (2024).

Table 2-8: Water Quality (Maximum Monthly Mean) Results for the Use of Passive/Active Flocculation During Operation in Post-closure using Typical Source Terms and Average Hydrology at Relevant Prediction Nodes

Location Creek	Parameter	BC WQG (2024) (mg/L)	Final EAC Project Case (2024) (mg/L)	Decrease TSS levels to 5 mg/L (mg/L)
Tenas Control Pond	Aluminum (t)	0.27	0.39	0.07
	Iron (t)	1.0	1.5	0.2

Notes: %=percent; BC=British Columbia; EAC=Environmental Assessment Certificate; WQG=water quality guidelines. Red text indicates exceedances of WQGs.

Storage and Use of Freshet Water

Telkwa Mining has investigated the storage and use of Freshet water from Channel C02 that diverts water around the Project into Four Creek. The use of water from the C02 channel is to improve the robustness of the water cover for PAG material in the management ponds especially the East Management Pond.

The change in the storage and use of freshet water was incorporated into the WLBM report completed by SRK which is provided in **Appendix 10: Effect of Mitigation Controls on Water Quality and Quantity of the Tenas Project, SRK**, with **Table 2-9** below providing a summary of these results for the relevant prediction nodes. Given the minor reductions in parameter concentrations in the receiving environment and that this option is inconsistent with the best management practice of keeping noncontact water out of the Project, this mitigation control was not carried forward into the Final EAC Project Case (2024).

Table 2-9: Water Quality (Maximum Monthly Mean) Results for the Storage and Use of Freshet Water at Relevant Prediction Nodes

Location Creek	Parameter	BC WQG (2024) (mg/L)	Updated EAC Project Case (2024) (mg/L)	Additional C02 Water to MPs (mg/L)
WQSEA1 Goathorn Creek	Copper (d)	0.0012	0.0021	0.0021

Notes: %=percent; BC=British Columbia; EAC=Environmental Assessment Certificate; mg/L=milligrams per litre; WQG=water quality guidelines.
Red text indicates exceedances of WQGs.
Please note that dissolved copper exceeds the WQGs under background conditions.

Active Water Treatment

This mitigation control allows for the treatment of surface flows via various methods prior to water being discharged. This mitigation control was reviewed further using the subsequent BAT assessment process to select the appropriate technology for this Project and then determine if this technology was recommended.

Summary of BMP Assessment Process

Based on analysis above, **Table 2-10** below was generated which summarizes the results of the BMP Assessment process indicating which BMPs were selected for incorporation into the Final EAC Project Case (2024) and which technologies should be reviewed further in the BAT Assessment Process.

Table 2-10: Summary of the BMP Assessment Process

BMP / Technology	Incorporation into the Final EAC Project Case (2024)	Carried forward into the BAT Assessment Process	Comment
Additional use of water by the CPP	No	N/A	Not effective for the reduction of POCs in either seepage or surface discharge
Blasthole Liners	Yes	N/A	Incorporate into Final EAC Project Case (2024) as a source control technology
Storage and Use of Freshet Water	No	N/A	Not effective for the reduction of Parameters of Concern (POCs) in either seepage or surface discharges
Management and Control Pond Liner Modifications	N/A	Yes	Effective for reduction of seepage reaching downstream creeks
Passive/Active Flocculation	N/A	Yes	Effective for reduction some total parameter concentraions such as Iron
Active Water Treatment	N/A	Yes	Effective for reduction of POCs in surface water discharge to Goathorn Creek

BAT Assessment

As a reminder the Final EAC Project Case (2024) does not have exceedances in the receiving environment except for parameters that are already in exceedance for background/baseline conditions and a short duration (4 year) exceedance of cobalt in Four Creek which is likely not to occur if attenuation mechanisms in groundwater were accounted for in the water model.

As provided above the following mitigations were carried forward into the BAT process:

- Modified liners in the management and control ponds;
- Passive/Active Flocculation; and,
- Active water Treatment.

SRK identified several Parameters of Concern (POCs) based on the guidance definition provide by the Ministry of Environment for the Updated EAC Project Case (2024) WLBM using typical source terms. Potential water treatments could be applied to try and meet BC WQGs at the end of pipe and the receiving environment. To that effect, Telkwa Mining contracted SRK to complete a BAT assessment on available treatment technologies for these POCs using the guidance provided by the BC provincial government and SRK's full report is provided in **Appendix 11: Tenas Project Best Achievable Technology Assessment Updated, SRK**. A multi-step process that mirrored the 2024 guidance provided by BC ENV was followed as summarized by **Figure 2-7** below.

Table 2-11 below summarizes the results obtained by the MAA for the various water treatment technologies that were carried forward from screening analysis.

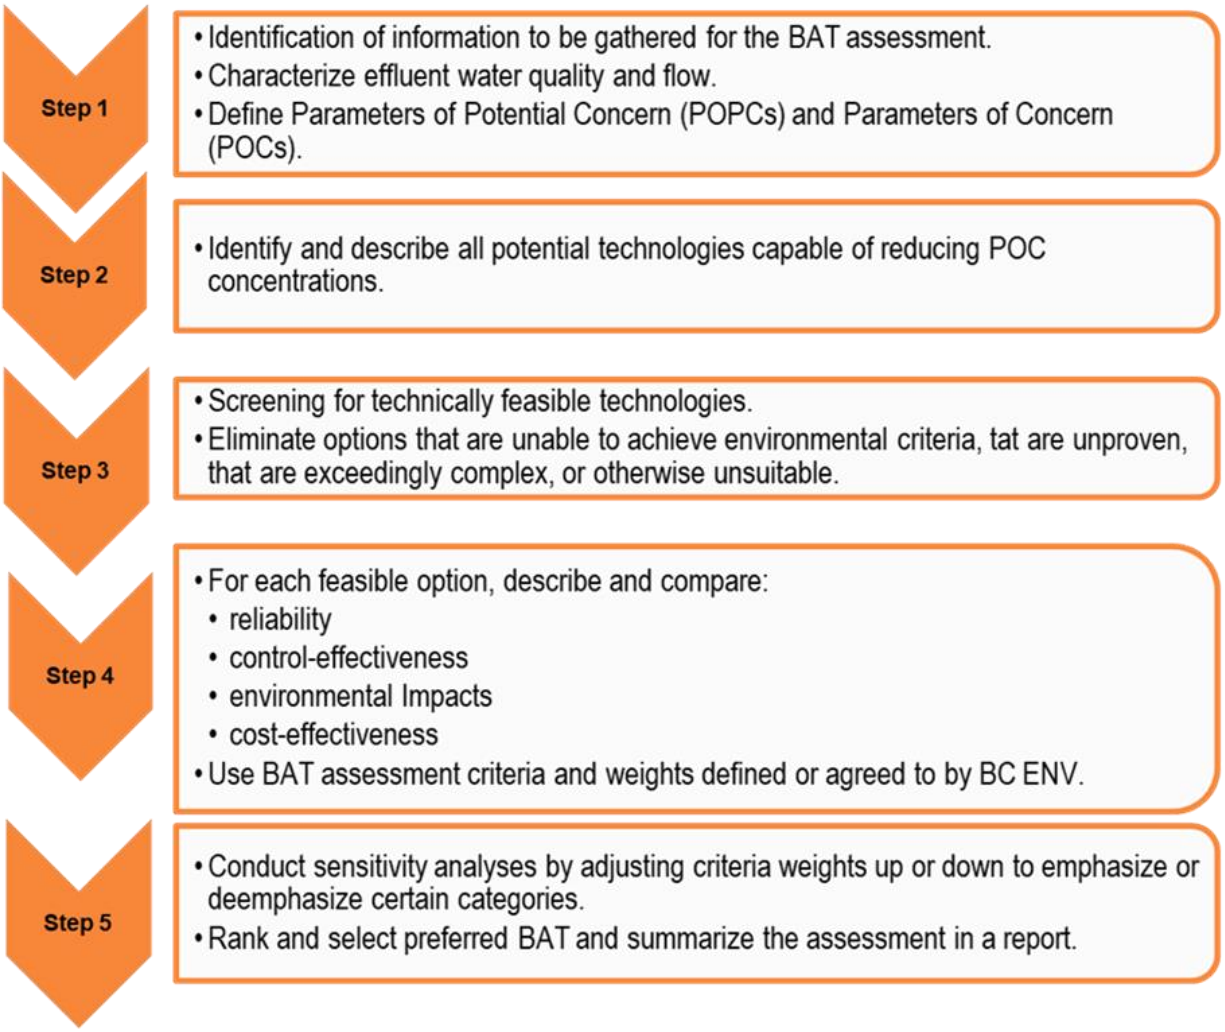

Figure 2-7: Bat Methodology Based on BC ENV's 2024 Guidance Document

Table 2-11: Summary of MAA Rankings for Active Water Treatment Technologies that Met Screening Requirements

		Base Case with BMPs	Passive/Active Flocculation	In-situ Active (GBR)	RO + MBBR	RO + MBBR + HDS Lime	RO + MBBR + Sulphide	RO + MBBR + Ferric	RO + MBBR + Ion Exchange	Zero Liquid Discharge	Modified Liners in Water Management Ponds

Source: https://srk.sharepoint.com/sites/NACAPR002055/Internal/BAT Assessment/Telkwa BAT Tech Screening REV01.xlsx

Based on the above table, the top ranking of the water treatment technologies is:

1. In-situ Active GBR and Base Case with BMPS/BATS with no additional mitigations;
2. Passive/Active Flocculation;
3. Modified Liners in Management and Control Ponds;
4. RO + MBBR and RO + MBBR + Ion Exchange; and,
5. RO + MBBR + HDS Lime and RO + MBBR + Sulphide.

The modelled water quality output for two selected water treatment systems (Options 1 In-situ Active GBR and 5 RO + MBBR + HDS Lime) is provided in **Appendix 10: Effect of Mitigation Controls on Water Quality and Quantity of the Tenas Project, SRK**, with **Table 2-12** providing a summary of these results for the selected nodes. Given the results of the BAT assessment, and the impact on water quality in the receiving environment these two additional mitigations were not selected to be incorporated into the Final EAC Project Case (2024) as no exceedance was found in the receiving environment but rather these mitigations will only be incorporated via an approved Trigger Action Response Plan in permitting.

Table 2-12: Water Quality (Maximum Monthly Mean) Results for Active Water Treatment of Surface Flows in Post-closure using Typical Source Terms and Average Hydrology at Relevant Prediction Nodes

Location Creek	Parameter	BC WQG (2024) (mg/L)	Updated EAC Project Case (2024) (mg/L)	In-situ Active GBR Treatment (mg/L)	Active Treatment RO+MBBR+HDS Lime (mg/L)
WQSEA1 Goathorn Creek	Copper (d)	0.0013	0.0021	0.0021	0.0020
WQSO6 Goathorn Creek	Copper (d)	0.0013	0.0021	0.0021	0.0020
WQS03-DS Four Creek	Cobalt (t)	0.004	0.00068	0.00075	0.00069
	Nitrite (t)	0.020	0.015	0.010	0.015
	Sulphate (t)	309	33	44	34
	Selenium (t)	0.0020	0.00081	0.00066	0.00085
WQS04 Tenas Creek	Copper (d)	0.0026	0.0015	0.0016	0.0015
	Nitrite (t)	0.020	0.0090	0.0033	0.0091
	Sulfate (t)	218	24	36	24
	Selenium (t)	0.0020	0.00078	0.00033	0.00079

Notes: %=percent; BC=British Columbia; EAC=Environmental Assessment Certificate; mg/L=milligram per litre; WQG=water quality guidelines.
Red text indicates exceedances of WQGs.

Please note that dissolved copper exceeds the WQGs under background conditions.
Please note the current proposed configuration active water treatment does not affect groundwater seepage which is the causes of elevated POCs in Four and Tenas Creeks

Incorporation of Further Mitigations for the Final EAC Project Case (2024) based on the BAT and BMP Assessments

A review of the mitigation options was completed based on the BMP and BAT assessments completed above with the results summarized in the **Table 2-13** below to help guide how and when mitigations will be incorporated into the Final EAC Project Case (2024).

Table 2-13: Summary of Further Mitigations/Technologies Incorporated or Discarded for the Final EAC Project Case (2024) Based on the BAT and BMP Assessments

Mitigation	BAT or BMP	Recommendations
Management and Control Pond Liners	BAT	• Do not adopt in the Final EAC Project Case (2024). • Adopt as a contingency to be implemented via a Trigger Action Response Plan in permitting for West Management Pond. • Submit during Permitting phase for regulatory approvals.
Use of Blasthole Lines	BMP	• Adopt this option for the Final EAC Project Case (2024).
Use of passive/active flocculation in TCP and Rail Infrastructure Sedimentation Pond	BAT	• Do not adopt in the Final EAC Project Case (2024). • Adopt as a contingency to be implemented via a Trigger Action Response Plan in permitting. • Submit during Permitting phase for regulatory approvals.
Active Treatment of surface flows using RO+MBBR+HDS Lime	BAT	• Do not adopt in the Final EAC Project Case (2024). • Adopt as a contingency to be implemented via a Trigger Action Response Plan in permitting. • Develop Permit level Design. • Submit during Permitting phase for regulatory approvals.
Passive Treatment of surface and seepage flows via Gravel Bed Reactors	BAT	• Do not adopt in the Final EAC Project Case (2024). • Adopt as contingency to be implemented via a Trigger Action Response Plan in permitting. • Develop Permit Level Design. • Submit during Permitting phase for regulatory approvals.

Based on the above information the Final EAC Project Case (2024) will incorporate blasthole liners as a further BMP beyond those already provided in the Updated EAC Project Case (2024) and EAC Project Case (August 2022).

Contingency Mitigations, in accordance with a Trigger Action Response Plan

Following a meeting with EAO, BC Ministry of Environment, and BC Ministry of Mining & Critical Minerals on December 8, 2025, Telkwa Mining understands that the Province of BC is concerned

with potential uncertainty associated with the predictive modelling of water quality from greenfield mining projects and the use of In-situ Active GBRs as a primary mitigation means for addressing POCS. Telkwa Mining had SRK review and modify the BAT report to:

- Clearly recommend that RO+MBBR+HDS Lime is the primary mitigation to address future water quality concerns.

To deal with potential technology readiness concerns with the In-situ Active GBR water treatment technology, Telkwa Mining will commit to designing, permitting, and constructing a pilot In-situ Active GBR water treatment system in the CPP Sedimentation Pond or alternative pond as part of the Construction Phase so that this system is in place for monitoring its effectiveness for treating contact water and seepage from the Project to increase the technology level of this method to 8 or 9 for identified POCs (such as nitrogen species, selenium, metals).

Furthermore, to deal with potential uncertainty risks in the WLBM Telkwa Mining commits to designing both a permit level In-situ Active GBR and RO+MBBR+HDS Lime water treatment systems and applying for permit approvals for both contingency mitigations. By having permit approvals and permit level designs in place for constructing the In-situ Active GBR and/or the RO+MBBR+HDS Lime active water treatment systems will allow them to be constructed within approximately one year of making a final execution decision based on measured POC concentrations at the end of pipe, in the seepage, in the management and control ponds, and in the receiving environment during the Construction and Operation Phases prior to the POCs exceeding the BC WQGs in the receiving environment.

During annual monitoring specified during the permitting process, if it becomes evident that POCs will trend to be above the BC WQGs in the future, some or all the following additional contingency mitigations can be implemented for the Project based on a Trigger Action Response Plan that will be provided and approved during permitting:

- Implement water treatment for surface and seepage water flows using the In-situ Active GBR water treatment method in the management ponds as these ponds will be constructed with the necessary infrastructure already incorporated to allow for the construction of this water treatment process.
- Implement passive/active flocculation for the reduction of total parameter concentrations in sedimentation and control ponds.
- Implement RO+MBBR+HDS lime active water treatment into the Water Management Plan.
- As the liner for the WMP will not be constructed till after year 5 which allows the implementation of liner Modifications for the WMP prior to PAG being placed into the management pond if TARP indicates this is a requirement.

Construction and implementation of any of these contingency mitigations will be contingent upon, and in accordance with, an agreed upon consensus-based Trigger Action Response Plan (TARP) to be developed during the BC provincial permitting process. As an example, exceedances of defined parameter of concern concentrations measured by the water quality monitoring program at agreed upon locations, all as defined in the TARP, would trigger the construction of the RO+MBBR+HDS Lime (TRL 8 or 9) water treatment system. Construction of the water treatment system will not necessarily be during the Construction Phase or even during the Operation Phase of the Project, but rather will be based on monitoring of Parameters of Concern and modelling demonstrating that there will be exceedances of the identified permit limits in the future that will likely cause measured adverse impacts to aquatic receptors, and that the RO+MBBR+HDS Lime system would be able to treat. The TARP would have similar provisions for the other contingency mitigations noted above. This commitment is also contingent on the responsible permitting agencies agreeing to not incorporate the permitted water treatment facility (or other contingency mitigations) into bonding requirements until such time as the treatment facility (or other contingency mitigation) achieves commercial operation.

The Final EAC Project Case (2024) does not reflect the impact of adding these contingency mitigations to the predictions provided in the WLBM. However, TML had SRK investigate adding active water treatment technology **in Appendix 10: Effect of Mitigation Controls on Water Quality and Quantity of the Tenas Project, SRK** and is also included in **Appendix 12: Environmental Effects Assessment - Surface Water Valued Component** and provided in **Table 2-12** above. The Final EAC Project Case (2024) was included in the WLBM completed by SRK without active water treatment and is provided in **Appendix 1: Tenas Project, Water and Load Balance Modeling Report (Updated 2025), SRK**.

Summary of Final EAC Project Case (2024) Submitted

With the completion of the BAT assessment process and implementation of recommended additional mitigation controls the modelled effluent still does not meet all WQGs at discharge(end of pipe).

Telkwa Mining's and SRK's view is that all reasonable BMPs and BATs have been implemented for the Project and while the Project is not in the permitting phase, the implementation of an IDZ can be considered during the EAC application process for point source surface water discharges to provide modelled parameters in the receiving environment. After applying an IDZ which is provided in **Appendix 13, Tenas Project - Initial Dilution Zone Assessment (Final), SRK**, identified that POCs due to the Project meet the BC WQGs for the protection of aquatic life at the edge of the IDZ except for parameters that already exceed the guidelines under background/baseline conditions.

Table 2-14 below summarizes the results of the EAC Project Case (August 2022), and the Final EAC Project Case (2024) against the BC WQGs at selected prediction nodes after the application of an IDZ for surface water discharge into Goathorn Creek. The Final EAC Project Case (2024) is provided in **Appendix 10: Effect of Mitigation Controls on Water Quality and Quantity of the Tenas Project, SRK**.

Table 2-14: Water Quality (Maximum Monthly Mean) Results for EAC Project Case (August 2022), Updated EAC Project Case (2024), and Final EAC Project Case (2024) in Post-closure at Relevant Prediction Nodes

Location Creek	Parameter	BC WQG (2025) (mg/L)	EAC Project Case (August 2022) (mg/L)	Final EAC Project Case (2024) (mg/L)
WQSEA1 Goathorn Creek	Copper (d)	0.0013	Not Available	0.0016
WQS06 Goathorn Creek	Copper (d)	0.0013	0.0019	0.0016
WQS03_DS Four Creek	Cadmium (d)	0.00023	0.00026	0.000012
	Cobalt (d)	0.00050	0.00066	0.00063
	Nitrite (t)	0.020	0.038	0.0090
	Sulfate (t)	309	360	33
	Selenium (t)	0.0020	0.0058	0.00081
WQS04 Tenas Creek	Cobalt (d)	0.00045	0.00082	0.00029
	Copper (d)	0.0026	0.0031	0.0013
	Nickel (d)	0.0025	0.0031	0.00063
	Nitrite (t)	0.020	0.045	0.0056
	Sulfate (t)	218	260	24
	Selenium (t)	0.0020	0.0041	0.00079

Notes: %=percent; BC=British Columbia; EAC=Environmental Assessment Certificate; mg/L=milligram per litre; WQG=water quality guidelines.
Red text indicates exceedances of WQGs.
Please note that dissolved copper exceeds the WQGs under background conditions.

In the EAC Application, Telkwa Coal submitted water quality and quantity predictions based on a Project development scenario. Telkwa Mining, with support from SRK, then completed an assessment of implementing new mitigations requested by the ENV and EMLI to determine if POC concentrations can get closer and ideally below BC WQGs in the receiving environment. The additional mitigation of incorporating blasthole liners was incorporated into what is now considered the Final EAC Project Case (2024) for water quality and quantity predictions. This case does not have exceedances of any parameters in the receiving environment except for dissolved cobalt for a short duration (four years) at one of the downstream Prediction Node in Four Creek.

Dissolved copper was also in exceedances in Goathorn Creek, but this parameter was above the WQG in the background/baseline. The effects assessment on the Surface Water Valued Component was updated to reflect the results of the Final EAC Project Case (2024) and using a local study area which is provided **Appendix 12: Environmental Effects Assessment - Surface Water Valued Component**. In summary, there is no change to the conclusion that was presented in the EAC Application submitted in 2022 which stated "**no significant adverse residual effects**" from the Project on the Surface Water Valued Component are expected.

Telkwa Mining believes the information in the attached appendices and the above information addresses the requirements set forth in IR **Theme 1**.

THEME 4: CONDUCT ADDITIONAL WATER QUALITY PREDICTIONS USING RECENT SENSITIVITY ANALYSIS OF THE SEMI-PERMEABLE POND LINER

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

Recent sensitivity analysis of the semi-permeable pond liner to conduct additional water quality predictions is missing from the Application.

FOLLOW UP 1 - 356a ITT TABLE

Thank you for conducting the additional analysis and presenting the results at WQS03_DS and WQS04 at (post?) closure in the memo. Neither of these locations would be affected by the resultant increase in the surface discharge to Goathorn Creek, which was the concern underlying the original comment.

For discussion purposes, please consider Figure 4-8 of Appendix 4.3A: Water and Load Balance Modelling Report. Between 2045 and 2050, the cover water in the NMP has a higher selenium concentration than the pore water. Assuming a lower permeability liner, more cover water would be discharged to Goathorn Creek via the proposed surface discharge, commensurate with the reduction in pore water seepage under the ponds. This could result in an increase in selenium concentration in Goathorn Creek downstream from the discharge point.

Cover water concentrations also exceed pore water concentrations while the ponds are being actively loaded with the PAG material.

Using the 15% seepage reduction model (and commensurate increase in surface discharge), please provide a QP certified memo, including graphs predicting water quality (POCs only) at WQS06 from operations through post closure. Estimate water quality in Goathorn Creek at the effluent discharge point and WQS06. [EA Information Requirement]

IR LETTER 356 AND FOLLOW UP 2 – 356b ITT TABLE

Have a QP run three new WLBM scenarios:

- *Reduce the seepages through the management pond liners by 90% relative to the project case (with a commensurate increase in surface discharge). This scenario simulates blinding of the pond liners.*
- *Reduce the seepages through the management pond liners by 90% and assume low flow conditions (modified alternate case 5: 7Q10 low flow).*
- *Reduce the seepages through the management pond liners by 90% and assume high source term conditions (modified alternate case 2: high source terms).*

RESPONSE 356 ITT TABLE AND 356 ITT TABLE

This request is in relation to the request by ENV about the range in permeability that the soil-bentonite liner may experience due to construction variability which was provided during the round 1 IR as +/- 15%. Telkwa Mining has been requested to provide revised water quality predictions at EA1 assuming a 15% decrease in seepage under typical hydrology conditions, an 90% decrease in seepage under typical hydrology conditions, 90% decrease in seepage using 7Q10 low flows, and for a 90% decrease in seepage and high source terms under typical hydrology conditions.

While Telkwa Mining understands the need to review various scenarios, the 7Q10 scenario is not likely as during low flows the various management and control ponds will not be discharging to the environment as the Project will be keeping all water on site during this event to ensure the water covers are maintained for the various management ponds.

Table 2-15 below provides the summary of the results at relevant prediction nodes for the various parameters.

Table 2-15: Water Quality Results (Maximum Monthly Mean) for Seepage Scenarios at in Post-closure using Typical Source Terms and Average Hydrology at Relevant Prediction Nodes

Location Creek	Parameter	BC WQG (2025) (mg/L)	Final EAC Project Case (2024) (mg/L)	15% reduction in seepage and expected source terms (mg/L)	90% reduction in seepage and expected source terms (mg/L)	90% reduction in seepage, 7Q10 flows, and expected source terms (mg/L)	90% reduction in seepage and High source terms (mg/L)

Please note that dissolved copper exceeds the WQGs under background conditions.

FOLLOWUP COMMENTS

IR LETTER 356 AND 356 ITT TABLE

Add a new node to the WLBM in Goathorn Creek, 100m downstream of the confluence with the tributary into which the effluent is discharged. For the 3 scenarios listed above, for each node where a parameter is predicted to exceed a chronic BC WQG PAL, graphically illustrate water quality (for the exceeding parameters only) at those nodes from baseline through to post closure. On each graph, show the chronic BC WQG for the most sensitive use or value.

RESPONSE 356 ITT TABLE

This prediction node has been added to the WLBM and is identified as WQSEA1. Please find attached **Appendix 6: Tenas Project Information Request Responses Related to Surface Water Valued Component, SRK** which is a technical memo addressing the IR questions posed by ENV about the WLBM for a complete list of parameter concentrations and supporting graphs.

IR LETTER 356 AND 356 ITT TABLE

[Figures 2.2-2.4 of Appx 4.3 (WLBM report) show Four Creek joining Goathorn Creek at WQS05, instead of WQS06. Is this an error in the diagram? If so, has this error been incorporated into the model?]

Four Creek joins Goathorn Creek above WQSO6 (even above EA1) while Tenas Creek joins Goathorn Creek above WQS05 which has been verified as correct in the model. The figures have been corrected and included in **Appendix 6: Tenas Project Information Request Responses Related to Surface Water Valued Component, SRK**.

Telkwa Mining believes the responses above in addition to those provided in the attached **Appendix 6: Tenas Project Information Request Responses Related to Surface Water Valued Component, SRK** address the requirements set forth in IR **Theme 4**.

THEME 3: HAVE A QUALIFIED PROFESSIONAL IDENTIFY LENTIC AREAS IN THE RECEIVING ENVIRONMENT WHICH MAY RECEIVE SELENIUM FROM MINE OPERATIONS, AND ENSURE THAT BACKGROUND CONCENTRATIONS OF SELENIUM IN WATER, SEDIMENT, INVERTEBRATE, AND FISH TISSUES ARE COLLECTED AND COMPILED IN THOSE LENTIC AREAS

FOLLOWUP COMMENTS

IR LETTER NEW AND 520 ITT TABLE

Have a qualified professional identify lentic areas in the receiving environment which may receive selenium from mine operations, and ensure that background concentrations of selenium in water, sediment, invertebrate, and fish tissues are collected and compiled in those lentic areas.

RESPONSE 520 ITT TABLE

There are no lentic areas in the current receiving environment based on a review by Palmer Environmental as provided in **Appendix 14: Tenas Coal Mine Information Request # 498, 500-504, and 520 - Expert Advice Regarding Fish and Fish Habitat Within the Project Area, Palmer Environmental, Palmer Environmental** attached.

As part of permitting an Aquatic Effects Monitoring Program (AEMP) will be submitted describing the monitoring that will be completed in relation to all aspects of the Project including selenium concentrations and their species.

Telkwa Mining believes the responses provided above and in **Appendix 14: Tenas Coal Mine Information Request # 498, 500-504, and 520 - Expert Advice Regarding Fish and Fish Habitat Within the Project Area, Palmer Environmental, Palmer Environmental**, address the requirements set forth in IR **Theme 3**.

THEME 6: OTHER ITT TABLE COMMENTS

FOLLOWUP COMMENTS

FOLLOW UP 306 ITT TABLE

Due to the high consequence and likelihood of selenium speciation occurring as a result of reducing conditions commonly observed in lentic waters these processes should be included in the modelling. In addition, in order to have informative data to base impacts to the receiving environment on a water sampling node should be created a maximum of 100 meters downstream of the proposed discharge location. Currently, it appears that WQS06 is the nearest downstream node at approximately 4.3 km from the proposed discharge (refer to comment 319) [EA Information Requirement].

RESPONSE FOLLOW UP 306 ITT TABLE

Telkwa Mining acknowledges the comment and after discussion with EMLI in 2023 and QPs, the model cannot include the required modelling included in the model as it is difficult to predict with any degree of confidence what species of selenium produced and what concentrations might be present. It was agreed at the last meeting with the water sub-working group that this modelling would no longer be required.

Telkwa Mining has added a new prediction node labelled EA1 at point approximately 100 m from the discharge point into Goathorn Creek for the Project. As the selenium concentration in the Final EAC Project Case (2024) is below the BC WQGs no adverse effect is expected as the value in this guideline is protective for all selenium species as there is no distinction provided in the guidelines in terms of selenium species. The requirement of additional selenium and selenium species monitoring in the existing environment and during the Construction and Operation Phases can be made a condition of the EAC Certificate.

FOLLOWUP COMMENTS

FOLLOW UP 307 ITT TABLE

Due to the potential for impacts to aquatic biota and resident fish populations, these impacts should be considered in a local context [EA Information Requirement].

LETTER IR 307 AND FOLLOW UP 307 ITT TABLE

Consider the impacts of exceeded BC water quality guidelines (WQGs), particularly to aquatic biota and resident fish populations, at a local scale rather than regional scale.

RESPONSE FOLLOW UP 307 ITT TABLE

Please find the response for this ITT in the attached **Appendix 6: Tenas Project Information Request Responses Related to Surface Water Valued Component, SRK**.

Telkwa Mining has implemented an additional mitigation use a pipeline to transport discharge from the Tenas Control Pond to Goathorn Creek in the Construction, Operation and Decommissioning and Reclamation Phases and will only use the existing channel once end of pipe parameter concentrations will not cause effects to fish and fish habitat in this channel.

In summary Telkwa Mining had SRK revise the effects assessment for the Surface Water Valued Component based on the Local Study Area versus the Regional Study Area and still found there were no significant adverse effects due to the Project on the Surface Water Valued Component.

FOLLOWUP COMMENTS

FOLLOW UP 310 ITT TABLE

It sounds like this stream will no longer provide any significant ecological function. This is an issue under the federal Fisheries Act and may need attention from MLWRS and/or DFO.

RESPONSE FOLLOW UP 310 ITT TABLE

The stream currently does not have flow for most of the year and only in major storm events and for a brief period in freshet is there any water flows present in this ephemeral channel, as its catchment is extremely limited under background/baseline conditions. Based on the background/baseline site assessment completed for fish and fish habitat as part of the EAC Application this tributary does not provide viable fish habitat according to QPs. The photo **(Figure 2-8 below)** below illustrates this stream during the October 2023 rainy season with no signs of water by the leaf debris left in the channel.

Figure 2-8: Tributary to Goathorn Creek During the October 2023 Rainy Season

FOLLOWUP COMMENTS

FOLLOW UP 319 ITT TABLE

Thank you for your response. It appears as though the closest downstream prediction node from the discharge location is WQS06, located approximately 4.3 km from the point of discharge. It would be useful to have a prediction node closer to the point of discharge, perhaps 100 meters downstream of confluence of unnamed tributary to Goathorn Creek and Goathorn Creek [EA Information Requirement].

RESPONSE FOLLOW UP 319 ITT TABLE

Telkwa Mining has added a new prediction node labeled EA1 at the point approximately 100 m from the discharge point into Goathorn Creek for the from the ephemeral tributary.

FOLLOWUP COMMENTS

FOLLOW UP 350 ITT TABLE

It appears that Water Quality Guidelines for selenium, nitrite, and sulphate (and dissolved cadmium in Four Creek) will be exceeded in approximately 4 or more kilometres of Four Creek, and 5 or more kilometres of Tenas Creek for up to half of the year (Nov-Apr) for more than ten years of the mine life. This is significant in magnitude, geographic extent, frequency, and duration. [Comment]

FOLLOW UP 350 ITT TABLE

Response for Comment 351 applies to this Round 1 Comment, however, Comment 351 remains unresolved, and that Round 1 Response does not address frequency and duration effects characteristics.

FOLLOW UP 351 ITT TABLE

I remain in disagreement with the scale at which effects to Valued Components are being assessed and, because of that, the residual effects characterization. TCL has changed this specific assessment metric to stream length, however, they still assess affects at the RSA scale. The fish, invertebrates and other VCs in Tenas and Four Creeks are predicted to be subject to potential impacts from multiple water quality constituents in more than 4 kilometres of creek (over 20 and 25% of the entire stream length per Attachment 351-1) during half of each year for 10 years of mine life. This is not low residual effects at the scale of the individual stream (most appropriate), or even at the scale of the entire Tenas Creek watershed (the LSA, more appropriate than the RSA).

RESPONSE FOLOW UP 351/350 ITT TABLE

Please find attached **Appendix 6: Tenas Project Information Request Responses Related to Surface Water Valued Component, SRK**, for a signed and stamped response.

Telkwa Mining has implemented an additional mitigation use a pipeline to transport discharge from the Tenas Control Pond to Goathorn Creek in the Construction, Operation and Decommissioning and Reclamation Phases and will only use the existing channel once end of pipe parameter concentrations will not cause effects to fish and fish habitat in this channel.

In summary Telkwa Mining had SRK revise the effects assessment for the Surface Water Valued Component based on the Local Study Area versus the Regional Study Area and still found there were no significant adverse effects due to the Project on the Surface Water Valued Component.

FOLLOWUP COMMENTS

352 ITT TABLE

This section of App4.3-A indicated that total selenium exceedances are expected in both winter and summer months. The characterization of residual effects in 4.3 Surface Water Quality chapter contradicts this. Clearly indicate when total selenium will be exceeded. [EA Information Requirement]

FOLLOW UP RESPONSE 352 ITT TABLE

The Final EAC Project Case (2024) Model results in the downstream node in Four Creek (WQS03DS) show no exceedances of the WQG for selenium during any period. The maximum Final EAC Project Case (2024) maximum mean monthly modelled concentration through this period is 0.00081 mg/L.

Similarly, the Final EAC Project Case (2024) Model results for the downstream node of Tenas Creek (WQS04), show no exceedances of the WQG for selenium during any period. The maximum mean monthly modelled concentration through this period is 0.00015 mg/L for the Final EAC Project Case (2024).

FOLLOWUP COMMENTS

385/387 ITT TABLE

Table 5.2-1 provides the screening of water quality parameters to determine COPCs for wildlife, and ECCC notes that maximum modelled mean monthly values were used. ECCC recommends using a more conservative water quality statistic (e.g., maximum concentrations) to determine COPC values that would not be protective of acute effects during sensitive life stages for wildlife (e.g., amphibian egg and tadpole development).

385/387 ITT TABLE

Comment provided by Provincial ENV Reviewer: TCL's previous response is that a mean value is a maximum value ("the maximum modelled mean monthly value means the maximum concentration that is predicted."). I would ask them to have a QP confirm whether any single discrete sample is predicted to exceed an acute BC Water Quality Guideline for the protection of the most sensitive use/value (wildlife or avian in this case).

RESPONSE 385/387 ITT TABLE

Please see **Appendix 6: Tenas Project Information Request Responses Related to Surface Water Valued Component, SRK**.

FOLLOWUP COMMENTS

FOLLOW UP 388 ITT TABLE

Provincial Reviewer Response: Adequately addressed. Aquatic receptors are expected to be more sensitive to aluminum than avian spp or wildlife (ENV 2021. Reformat of 1988 Aluminum Water Quality Guidelines). Despite this, I would recommend they include aluminum in their residual effects characterizations.

RESPONSE FOLLOW UP 388 ITT TABLE

Aluminum was not carried forward into a residual effects characterization as Aluminum concentrations with the Project are within the natural variability of background/baseline conditions. This is demonstrated by the Telkwa River having exceedances of Aluminum under background/baseline conditions while upstream prediction nodes do not have exceedances from the Project for Aluminum. If monitoring indicates that Aluminum is trending above WQGs in

Goathorn, Four, and/or Tenas Creeks, Telkwa Mining will implement a water treatment strategy for this parameter. **Table 2-16** below summarizes the Aluminum results for selected prediction node.

Table 2-16: Water Quality Results (Maximum Monthly Mean) for Aluminum at Relevant Prediction Nodes for Updated EAC Project Case (2024)

Location Creek	Parameter (total)	BC WQG (2024) (mg/L)	EAC Project Case (August 2022) (mg/L)	Updated / Final EAC Project Case (2024) (mg/L)	Comments
WQSOEA1 Goathorn Creek	Aluminium	0.27	N/A	0.099	Upstream of WQS06 and WQS05 P50 background/baseline 0.034 P95 background/baseline is 0.66

Notes: %=percent; BC=British Columbia; EAC=Environmental Assessment Certificate; mg/L=milligram per litre; WQG=water quality guidelines.
Red text indicates exceedances of WQGs.

FOLLOWUP COMMENTS

FOLLOW UP 389 ITT TABLE

Not adequately addressed. TCL's response is to argue why SPOs are appropriate thresholds for screening COPCs. ENV (and apparently ECCC) disagrees and believes unapproved SPOs are inappropriate to use in an EA process. Using WQGs to screen COPCs, we would screen, at the least, Aluminum, Cobalt, and Sulphate as parameters for further effects assessment and characterization, including for wildlife, avian and aquatic receptors.

RESPONSE FOLLOW UP 389 ITT TABLE

Table 2-17 (Table 5.2-1 from EAC Application) was revised based on the most stringent WQG available for fresh water/wildlife/avian and the Final EAC Project Case (2024) using the format of Table 5.2-1 from the EAC application. Please note Table 5.2-2 did not appear in the EAC Application.

Based on **Table 2-17** below no parameters were identified as Parameter of Interest in the receiving environment beyond Cobalt which as short-term exceedance (four years) of the WQGs. This parameter was also identified as POC in the BAT analysis provided in **Appendix 11: Tenas Project Best Achievable Technology Assessment Updated, SRK**. Based on this analysis no further mitigations are recommended beyond the best management practices and technologies already employed by the Project.

Telkwa Mining believes the details above and provided in attached appendices address the requirements set forth in IR **Theme 6**.

THEME 7: EMLI GEOSCIENCE CLARIFICATIONS

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

EMLI does not support the application of the concept that an entire zone can be designated potentially acid generating (PAG) or non-PAG based on an average weighed NPR. Application of an average weighed NPR implies that a portion of the material from that unit will become acid generating at some point in the future. Although the overall drainage from that storage area may be pH-neutral due to mixing with the non-PAG portion of the unit or non-PAG material from another unit, the current Management Plan does not address blending and the current source terms do not account for a blended non-PAG / PAG rock piles or covers that are exposed to allow advanced stage weathering and acidic hot-spots within the pile. Additional information should therefore be presented by the proponent to support this approach.

RESPONSE IR LETTER OVERVIEW

Telkwa Mining assumes the concern outlined in the statement above from EMLI is with *non-PAG* zones as the statement has no bearing on the PAG zones as the entire zone is submerged underwater as stated in the EAC Application section 1 even if portions of these zones are potentially *non-PAG* unless operational verification sampling provides evidence that portions of these zones could be managed as *non-PAG* based on operational NPR cut-off values and that they are also large enough to efficiently separate with the equipment available.

Telkwa Mining has identified that, even though an entire zone might be classified as *non-PAG* based on a comparison of its bulk composition to an NPR cut off of 2.0, that there might be a component of PAG rock both within the overall aerial extent of the zone and within the vertical thickness of the zone that may have to be managed appropriately to ensure ARD does not occur from separable PAG materials not being placed underwater. The source term for *non-PAG* material placement has assumed that appropriate segregation and mixing/blending has occurred within the vertical thickness during the mining process that a non-PAG landform (NPR > or equal to 2.0) is established for storage piles, embankments, and buttresses. If operational verification testing is conducted on PAG zones the same methodology will be used as what is used for *non-PAG* zones to identify any potential separable *non-PAG* material within PAG zones.

The following zone polygons can be identified as *non-PAG* using an NPR cutoff of 2.0 AP to 1.0 NP and their bulk geochemical properties:

- Overburden (Zone 0);
- Portions of Zone 1;
- Portions of Zone 4; and,
- Portions of Zone 8 (not mined as part of the EA Open Pit).

Table 2-18 summarizes the zone classification for materials at the Tenas Deposit based on their bulk geochemical properties.

Table 2-18: Material Zone Classification Based on NPR of 2.0

Material Zone Name	ARD Assignment in Mine Plan and EAC Application Based on an NPR of 2.0	Stratigraphic Location	Average Zone Weighted NPR
Zone 0 / Overburden	*non-PAG*	Till and overburden – topography to bedrock	17.5
Zone 1	*non-PAG* with potentially separable PAG zones	Bedrock surface to top of Seam e (minus Zone 1a)	3.1
Zone 1a	PAG	Select area above Seam e to bottom of Seam e	0.7
Zone 2 & 3	PAG	Bottom of Seam e to bottom of Seam c	0.8
Zone 4	*non-PAG* with potentially separable PAG zones	Bottom of Seam c to top of Seam b	2.6
Zone 5	PAG	Top of Seam b to top of Seam 1U	1.2
Zone 55	PAG	Top of Seam 1U to bottom of Seam 1L	1.9
Zone 6	PAG	Bottom of Seam 1L to bottom of Seam 1Lc	1.8
Zone 7**	PAG	Below Seam 1Lc to the bottom of Seam 1Ld	1.7
Zone 8**	*non-PAG* with potentially separable PAG zones	Below Seam 1Ld	5.0

** **Notes:** Zones 7 and 8 are not currently recovered within EA open pit design; (1) As understood all zones even bulk non-PAG zones contain some PAG material and in some cases these PAG materials could be large enough to segregate out during the mining process.

ARD=acid rock drainage; NPR=neutralization potential ratio; PAG=potentially acid generating

Figure 2-9 through **Figure 2-15** below illustrate the distribution of the average overall exploration drillhole weighted NPR values for rock zones mined within the EA Open Pit with polygons illustrated using an NPR cut-off of 2.0 with green exploration drillhole polygons being classified as *non-PAG* and red exploration drillhole polygons being classified as PAG.

Please note the **entirety** of Zones 1a, 2/3, 5, 55, and 6 were planned to be placed underwater in the EAC application and will continue to be planned to be placed underwater until verification testing is completed on blastholes demonstrate that *non-PAG* regions of a suitable size and thickness is present using an NPR cut off criteria of 2.0.

Please note this is for illustration purposes only as verification testing will be based on blastholes which will be completed on a much tighter spacing and be completed for every bench mined versus the entire length of an exploration drillhole.

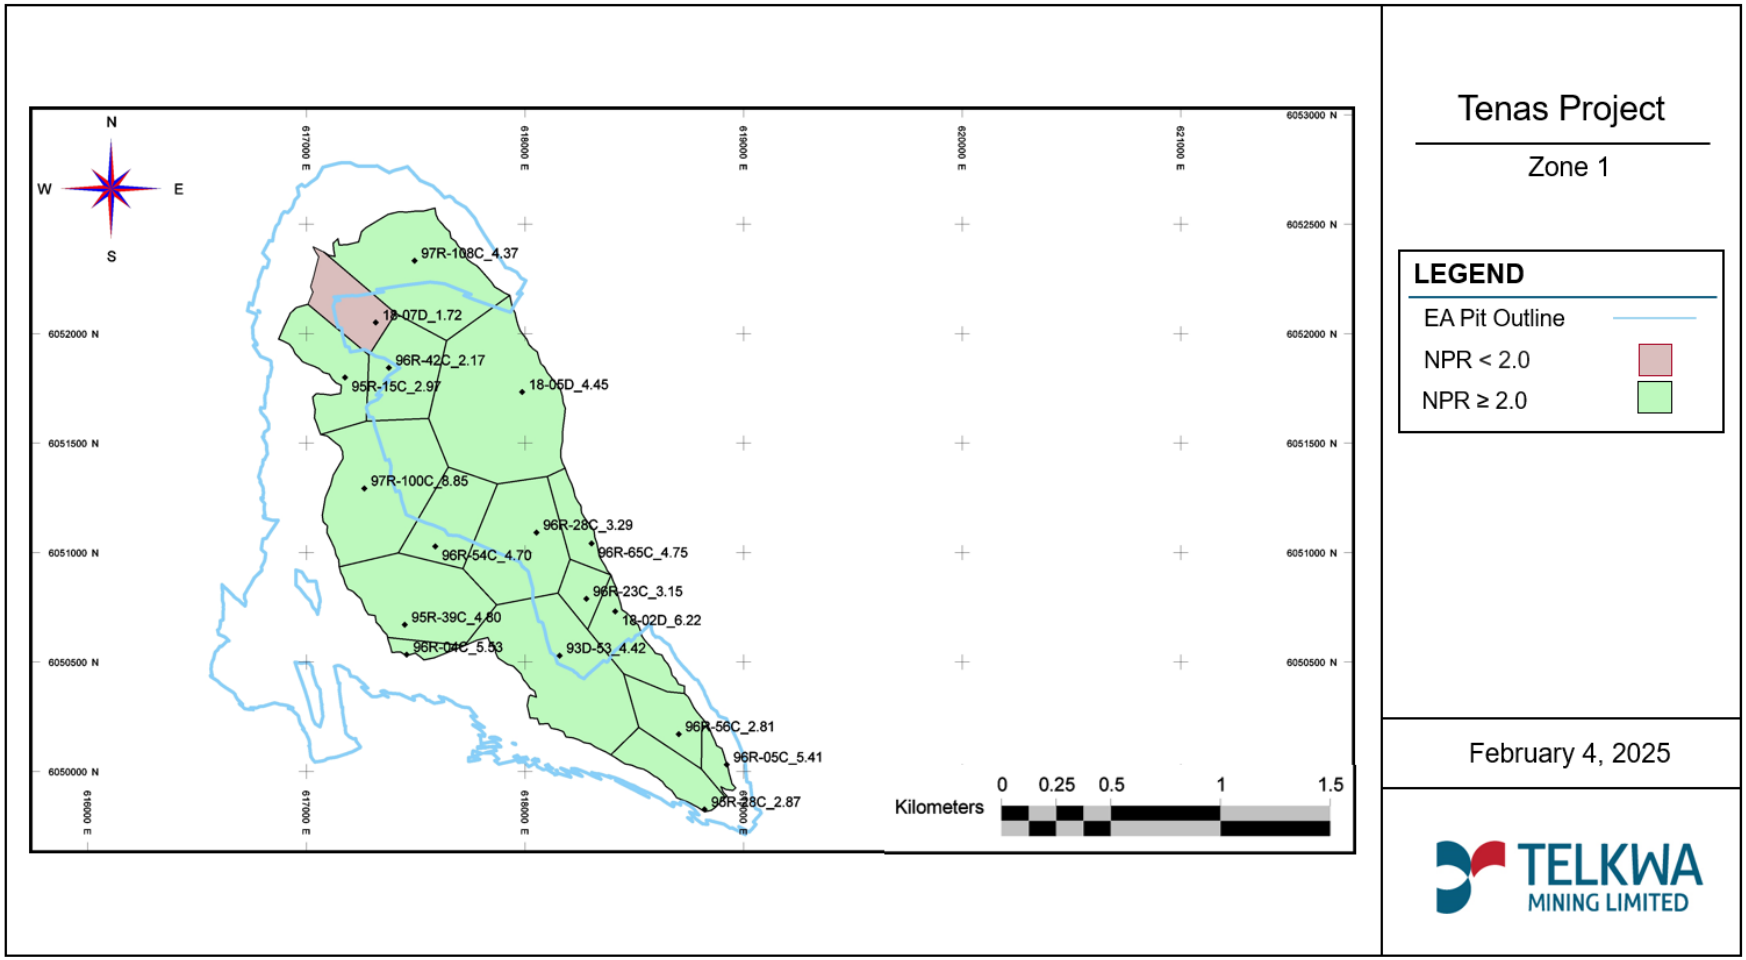

Figure 2-9: Zone 1 PAG and *non-PAG* Polygons Classified Against an NPR Cut-Off of 2.0, with Zones in Red Being Submerged Underwater in the EAC Application

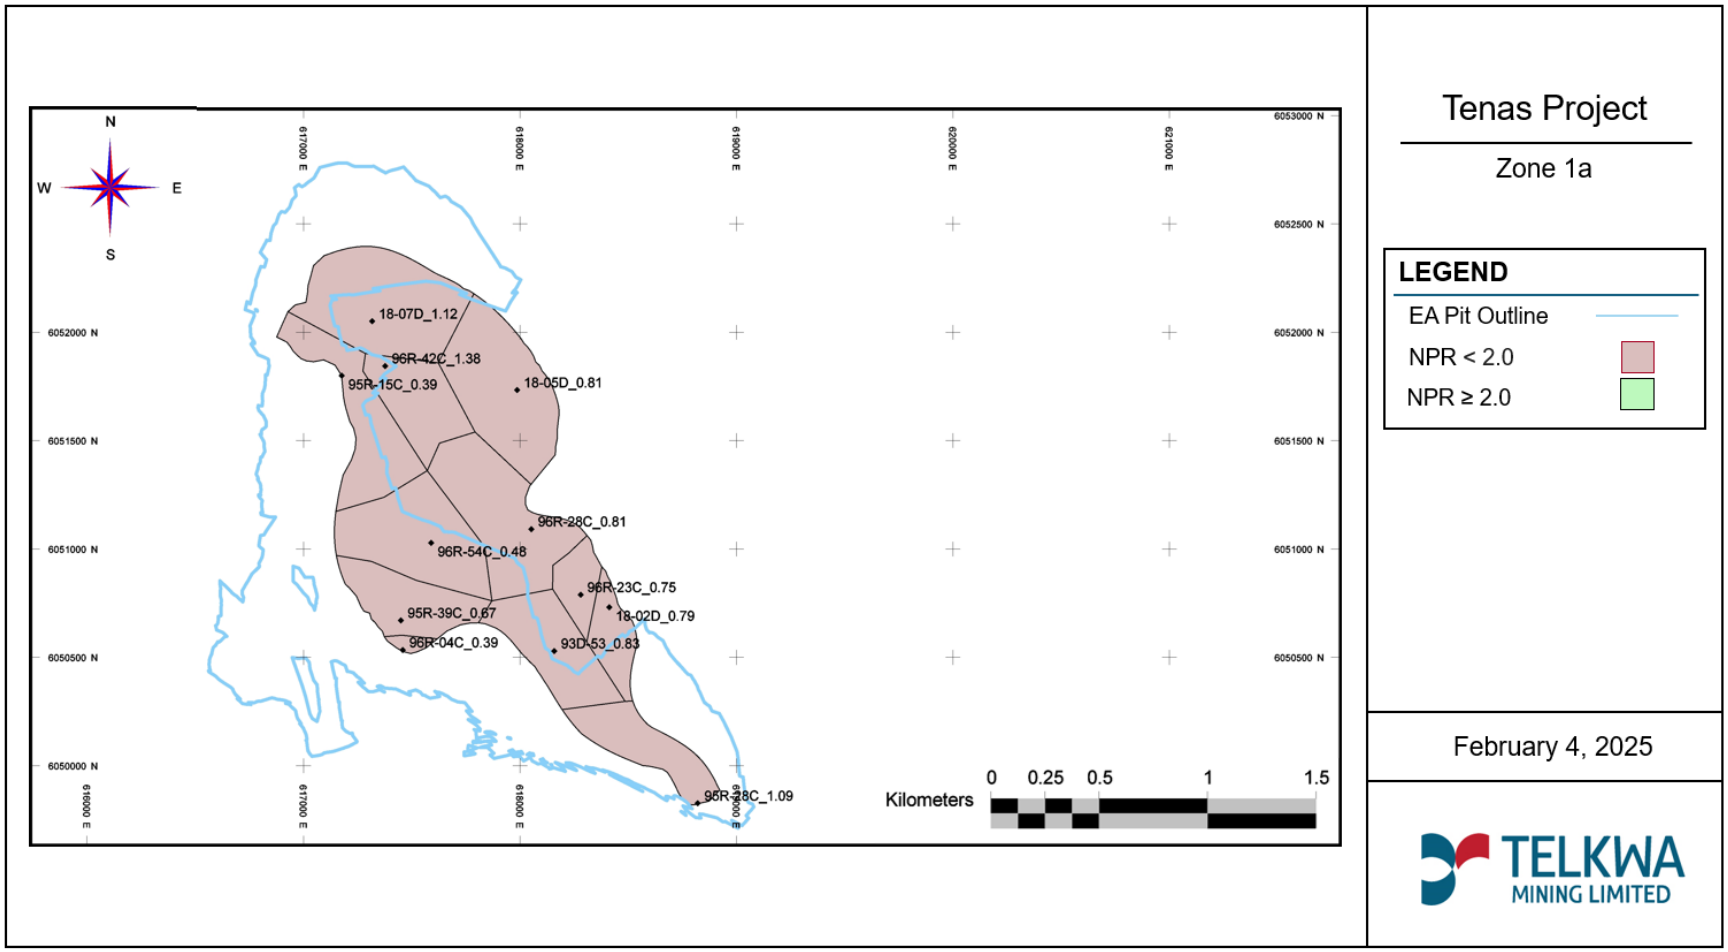

Figure 2-10: Zone 1a PAG and *non-PAG* Polygons Classified Against an NPR Cut-Off of 2.0, Entire Zone Treated as PAG in EAC Application and Submerged Underwater

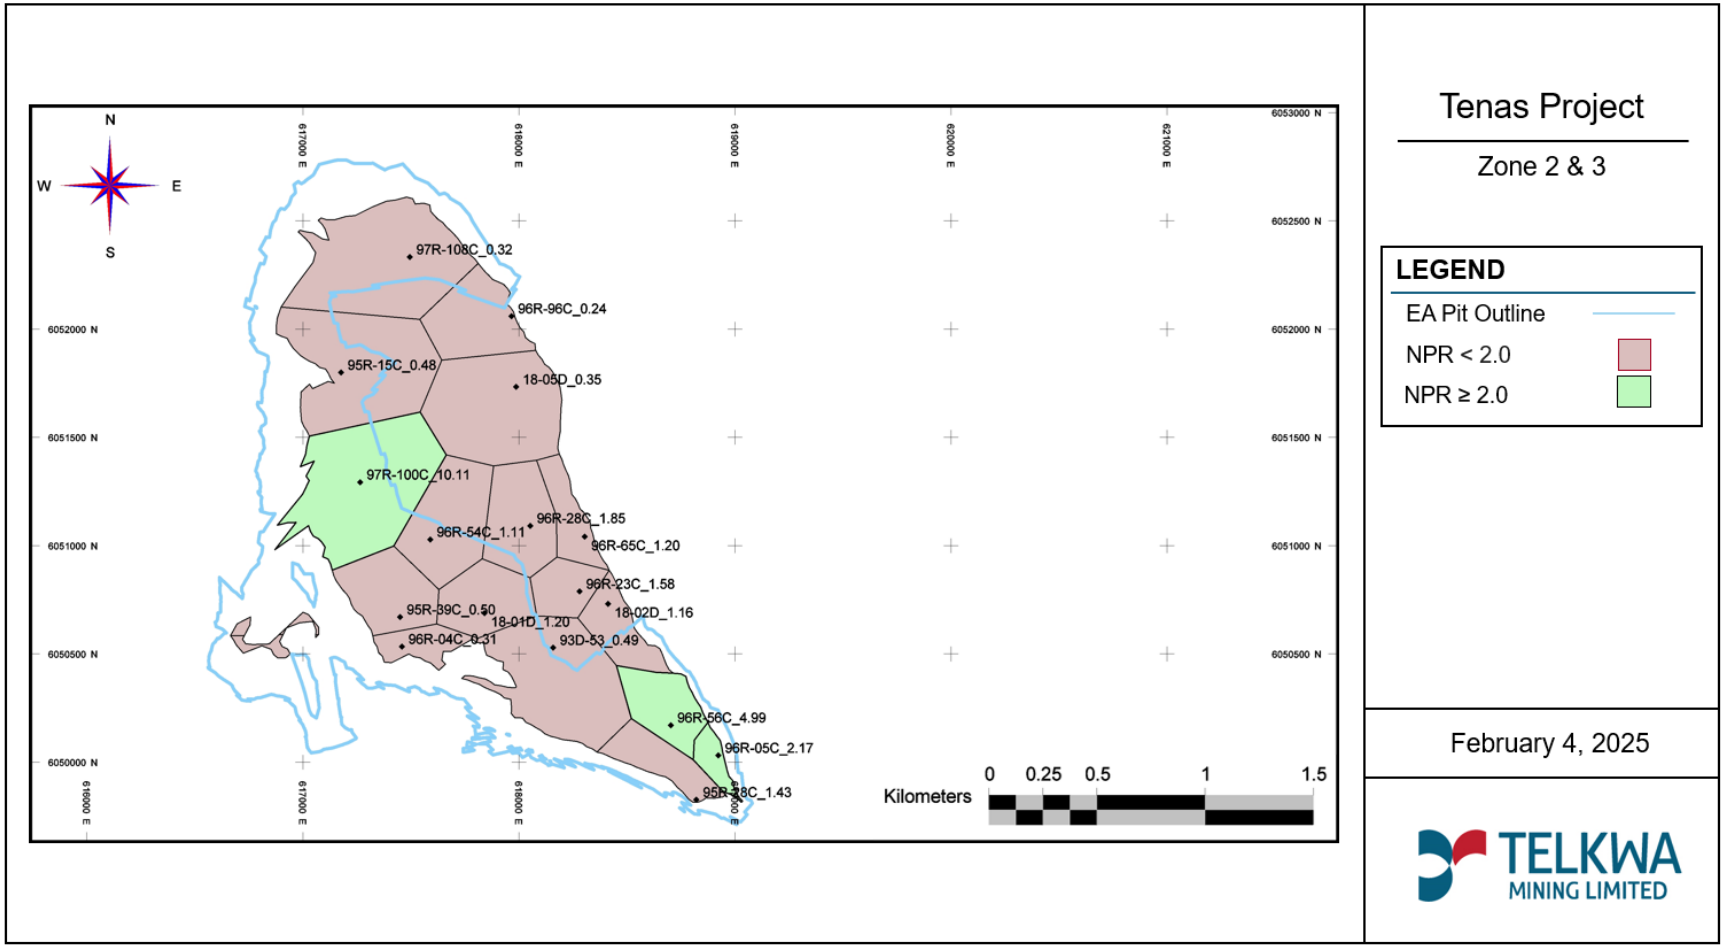

Figure 2-11: Zone 2/3 PAG and *non-PAG* Polygons Classified Against an NPR Cut-Off of 2.0, Entire Zone Treated as PAG in EAC Application and Submerged Underwater

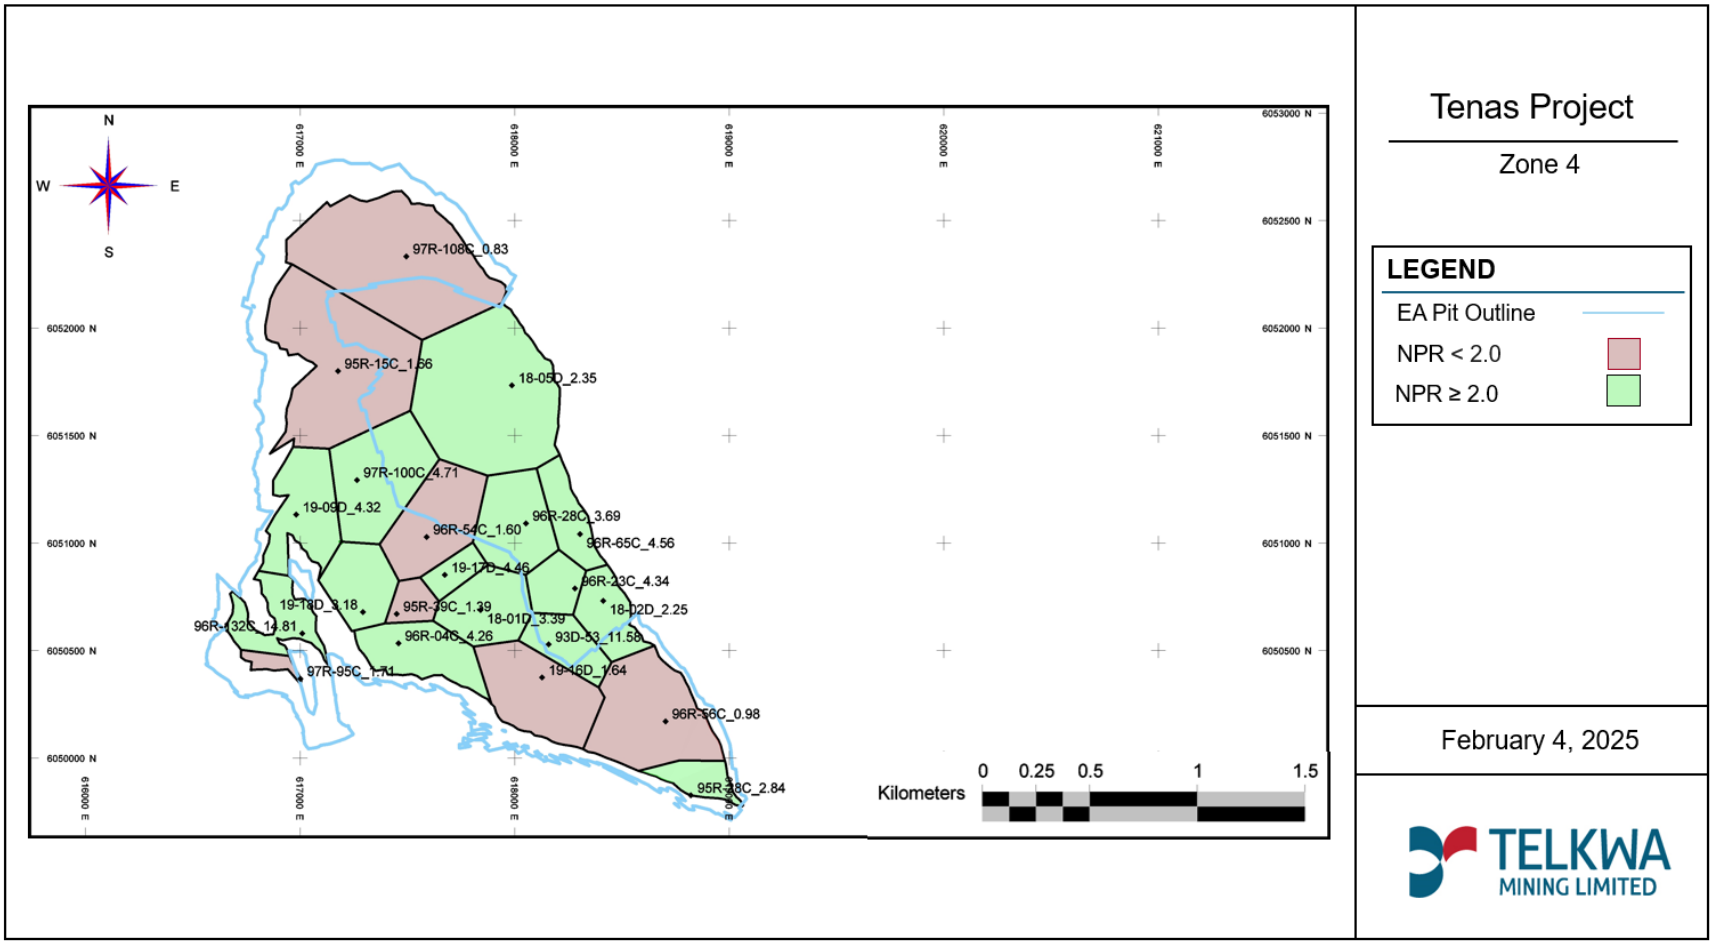

Figure 2-12: Zone 4 PAG and *non-PAG* Polygons Classified Against an NPR Cut-Off of 2.0, Red Polygons Submerged Underwater in the EAC Application

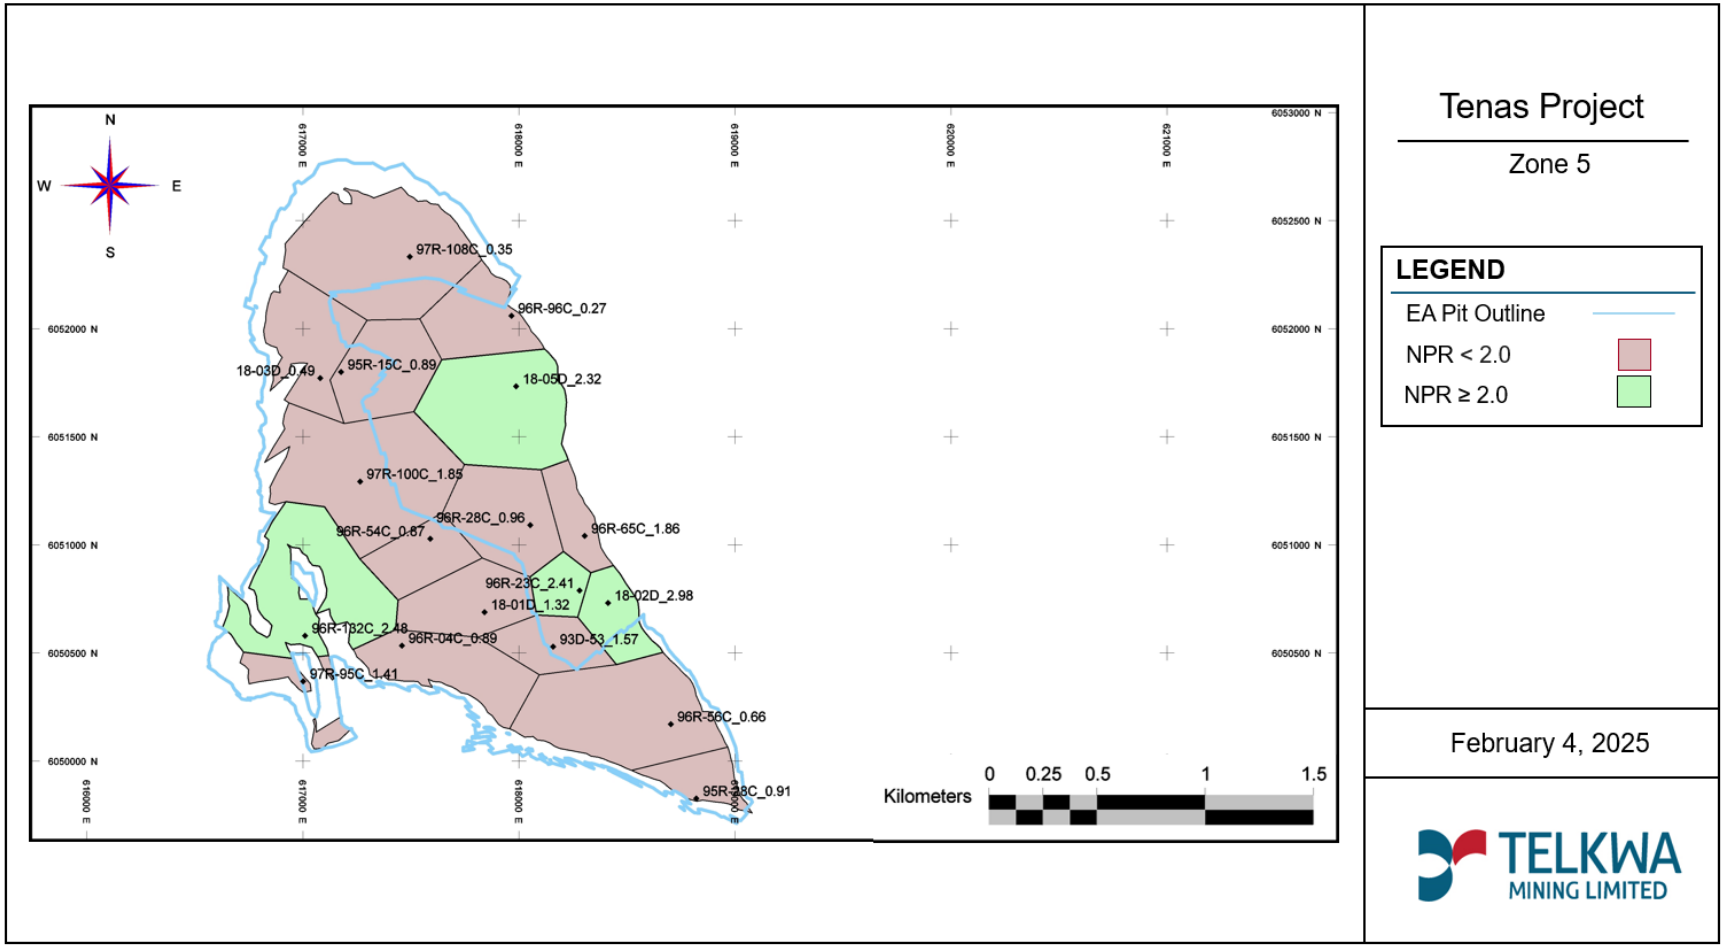

Figure 2-13: Zone 5 PAG and *non-PAG* Polygons Classified Against an NPR Cut-Off of 2.0, Entire Zone Treated as PAG in EAC Application and Submerged Underwater

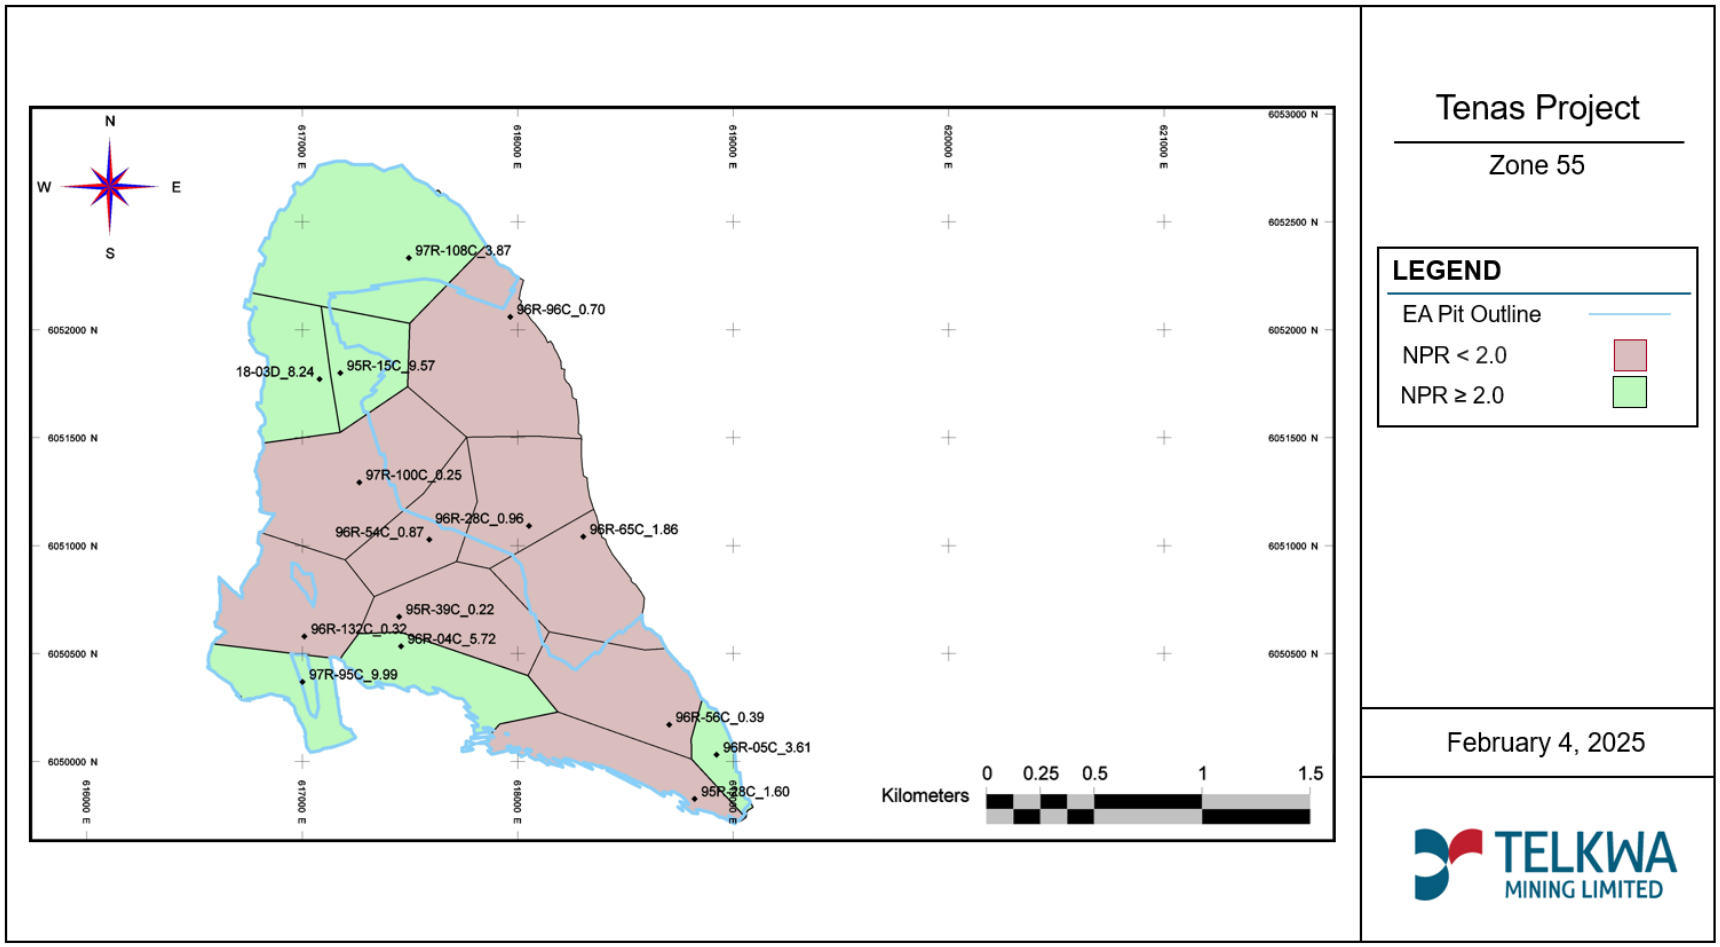

Figure 2-14: Zone 55 PAG and *non-PAG* Polygons Classified Against an NPR Cut-Off of 2.0, Entire Zone Treated as PAG in EAC Application and Submerged Underwater

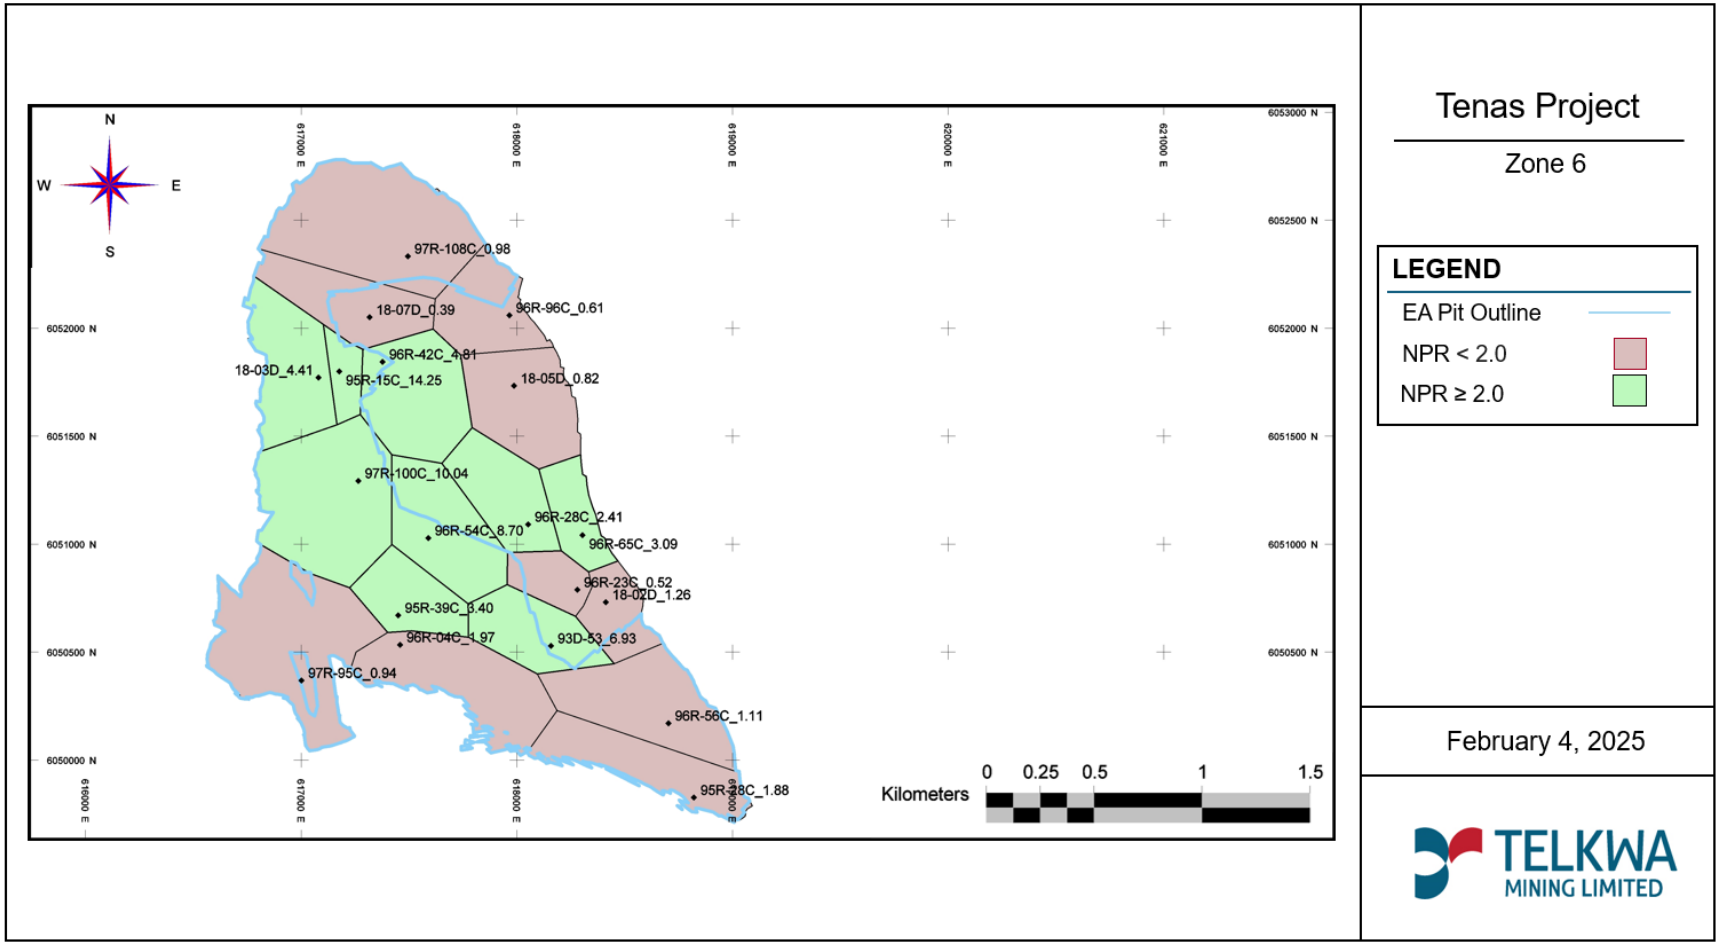

Figure 2-15: Zone 6 PAG and *non-PAG* Polygons Classified Against an NPR Cut-Off of 2.0, Entire Zone Treated as PAG in EAC Application and Submerged Underwater

As illustrated by the figures above, Zone 1 is the only zone that is almost entirely *non-PAG* on an aerial basis with only one exploration drillhole having an NPR less than 2.0 on an aerial extent (1.80) and Zone 1a is all PAG with no exploration drillholes having an NPR greater than or equal 2.0. Zones 7, and 8 have not been provided as there are no plans for mining of either of these zones and neither zone forms part of the EA Open Pit walls. Zones 1, 2/3, 4, 5, 55, and 6 have exploration drillholes that are both *non-PAG* and PAG based on the geochemical data collected using an NPR cutoff of 2.0. However, in the EAC application submission **all of zones 1a, 2/3, 55, 5, and 6 material** were classified as PAG and assumed to be placed underwater into the management ponds to be conservative for planning purposes while Zones 1, and 4 were demarcated into *non-PAG* and PAG polygons for the EAC Application based on the individual exploration drillhole NPR values on an aerial basis, distribution of material within the vertical column of exploration drillholes, and their locations respective to economic coal seams.

Note that these NPR values are only used for planning purposes and regulatory applications such as the EAC Application as the actual segregation of PAG from *non-PAG* will be based on field sampling and testing of blastholes with material being designated as PAG using a cutoff of an NPR 2.0 during the Construction and Operation Phases. The spacing of the blastholes will be on a much tighter spacing than exploration drilling can ever practically achieve.

Appendix 15: Tenas Project, Mine Material Management based on an NPR Cut-Off of 2.0, 1.80, 1.60, and 1.20, Telkwa Mining provides how Telkwa Mining would manage the various material zones would be managed if blasthole verification testing confirmed the exploration drillhole data and an NPR cut-off of 2.0 was used, or the EAC Application Methodology was used to classify PAG from *non-PAG* material. As demonstrated by **Table 2-19,** even when using an NPR value 2.0, a drillhole (exploration and/or blasthole) with a bulk property that would classify the entire drillhole polygon as *non-PAG* (NPR greater than 2.0) may have portions within the vertical length of a drillhole that may get placed underwater due to PAG intervals being present that can effectively be segregated (**Table 2-19**). **Table 2-19** indicates segregation is possible based on the drillhole interval NPR values.

Furthermore, some minor PAG units within an overall *non-PAG* drillhole polygon will become blended vertically within a polygon through the mining and blasting process into the surrounding *non-PAG* material so that the entire drillhole polygon can be considered *non-PAG* if these PAG zones are too small to be separated as illustrated by **Table 2-20**.

Finally, some geochemical zones in the EAC application that were classified as PAG might have polygons that could be managed as *non-PAG* during the Construction and Operation Phases. **Table 2-21** shows a Zone 6 exploration drillhole with a bulk NPR greater than 4.0 for this drillhole which could clearly be managed as *non-PAG* if confirmed by blasthole confirmation testing.

As the material zones mined with excavators/shovels will occur in approximately 12-m benches and a ML/ARD verification process will be conducted in advance of mining, any potential PAG or *non-PAG* material will be identified at a bench scale (12 m) as the sample interval recovered will be based on the planned mining horizon for the rock units within a blasthole. If sampling identifies separable PAG units within a mining horizon that require active management that can be mined efficiently with an excavator/shovel they will be managed as per the procedure provided as follows:

- For any separable PAG rock within blasthole polygons (defined as 2 times the burden and spacing distances) identified with an NPR less than 2.0 will need to be placed underwater within an average of 6 months and no longer than 12 months to mitigate the generation of ARD;
- Rock resulting from coal cleaning will be treated as PAG even if surrounding materials is *non-PAG* due to the inclusion of coaly materials into the rock;
- Rock materials will be treated as *non-PAG* if verification testing shows an NPR greater than or equal to 2.0 within blasthole polygons (defined as 2 times the burden and spacing distances);
- For overburden, surface soils, processed rock, rock construction materials, and non-rock construction materials will be treated as PAG if their NPR is less than 2.0, and verification testing will need to be done for these materials if they are to be treated as *non-PAG* as per the **ML/ARD Management Plan (ML/ARDMP; S13.0-C12)**; and,
- If verification testing is not completed, rock and processed rock will be treated as PAG.

Operational sampling committed to under the **ML/ARD Management Plan (ML/ARDMP; S13.0-C12)** provides sufficient data for final decision making on material segregation and placement as it has the necessary density and sample frequency needed to provide the certainty required for the protection of water quality and downstream environmental integrity.

Furthermore, at least one confirmation sample will be taken for each blast pattern which will be sourced from the reserve samples kept from the blasthole samples from the blast pattern. This sample confirmation requirement applies if only one type of geochemical material is consistently present for the entire blast being mined (i.e., all PAG or *non-PAG*). If more than one material type is identified based on the NPR cut off of 2.0 within an individual blast pattern a confirmation sample will be taken from each identified geochemical material which will be identified by material type, geochemical classification, zone, bench, lift number, blasthole, and blast pattern identifiers.

Lastly, random quarterly *non-PAG* rock pile samples will be taken from active *non-PAG* rock lifts in areas where rock has been placed during the last quarter. The number of samples will be based on an approximate 200 by 200-m grid pattern and taking a sample on every node of this grid. The

same criteria will be used as for operational blasthole verification testing with material having an NPR less than 2.0 being designated as PAG, while materials with an NPR greater than 2.0 being designated as *non-PAG*. If PAG material is identified by these grid points additional sampling will be conducted on approximately 25-m offset concentric circles from this location until a *non-PAG* sample is measured as illustrated by **Figure 2-16** below.

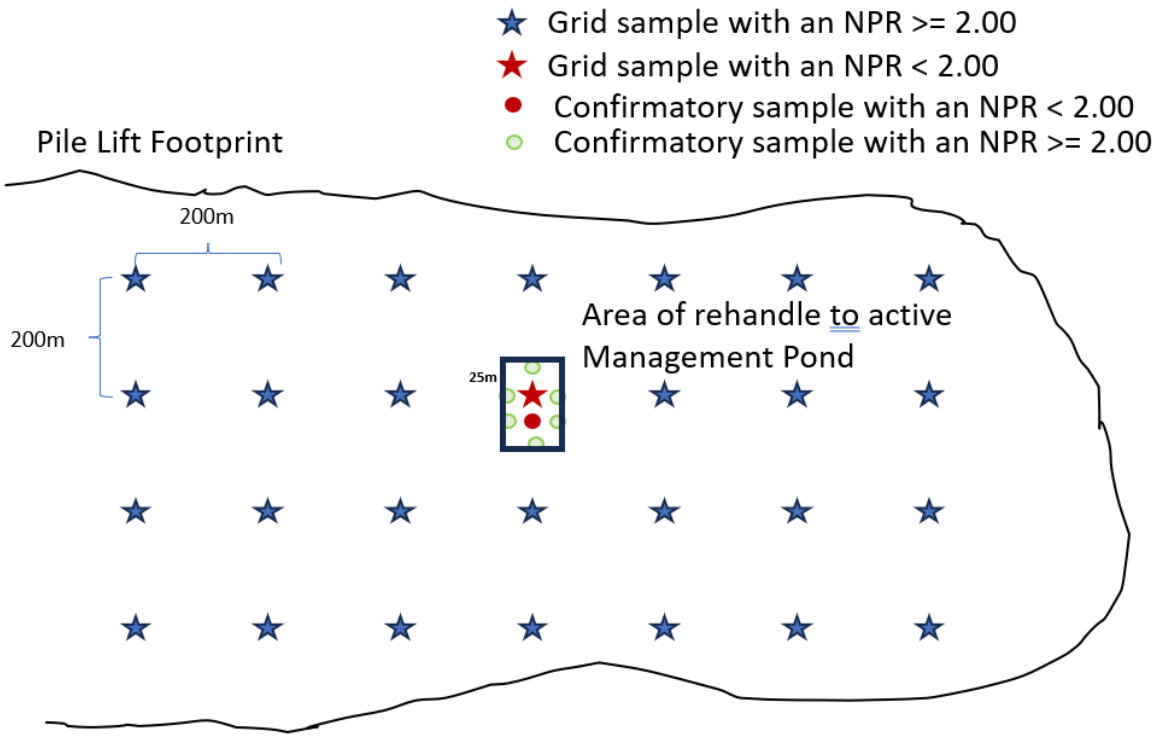

Figure 2-16: *Non-PAG* Pile Lift Material Confirmation Testing

Once the *non-PAG* rock pile lift area is defined by confirmatory testing and a bulk NPR and sulfur % has been calculated based on the sample testing completed; the following actions will be taken:

- If the bulk NPR for the sample is less than 2.0 an investigation will be completed, including a survey of the material's location and review of material that was placed there via the site electronic tracking system.
- Then a risk assessment will be conducted to determine if this this material will be rehandled and placed underwater in one of the active management ponds.

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

The current sampling frequency does not provide adequate information to define or refine PAG volume estimates beyond what they have specified in the ML/ARD Management Plan. Monitoring the geochemical characterization of ore, waste, and overburden must be based on proper sampling frequency representative of the proportional volume of sampled materials.

LETTER IR 136 AND 136 ITT TABLE

Indicate what additional sampling and characterization studies are planned to meet BC ML/ARD Guidelines. For instance, Zone 4 is underrepresented in the static test database.

FOLLOWUP COMMENTS

OVERVIEW IR LETTER

The metal leaching/acid rock drainage (ML/ARD) Management Plan in Section 6.4 specifies that all materials excavated from zones 1a and 2/3 will be managed as potentially acid generating (PAG). Material from zones 5, 55, and 6 were characterized as non-PAG but will be initially classified and managed as PAG unless testing can demonstrate otherwise. To facilitate the shorter turnaround times that are required to make operational decisions for placement of blasted rock, rejects, and other materials, the results of the geochemical characterization are used to develop operational proxies for determining NP and AP in an onsite laboratory that will be equipped with a Leco furnace. Section 6.1.3 of the ML/ARD Management Plan specifies an NPR of 1.2 is proposed to classify PAG mine rock at the Project. Clarifications and justifications on the ML ARD management plan and use of NPR 1.2 and 2 criteria as cutoff for verification and planning purposes should be provided.

IR LETTER 140, 142, 143, 146 and 148 AND 140a ITT TABLE

The ML/ARD Management Plan Section 6.4 specifies that all materials excavated from zones 1a and 2/3 will be managed as PAG. Material from zones 5, 55, and 6 were characterized as non-PAG but will be initially classified and managed as PAG unless testing can demonstrate otherwise. To facilitate the shorter turnaround times that are required to make operational decisions for placement of blasted rock, rejects, and other materials, the results of the geochemical characterization are used to develop operational proxies for determining NP and AP in an onsite laboratory that will be equipped with a Leco furnace. Section 6.1.3 of the ML/ARD Management Plan specifies an average weighted NPR of 1.2 is proposed to classify PAG mine rock at the Project.

1. *Provide clarifications and justifications for the proposed ML ARD management plan and use of weighed average NPR 1.2 and 2 criteria as cutoff for verification and planning purposes.*

RESPONSE 140a ITT TABLE

SRK has provided a response to this geoscience IR in **Appendix 16: Telkwa Coal Tenas Project Environmental Assessment Application – Responses to 2022 Supplemental Geochemistry Information Requests from the Ministry of Energy, Mines and Low Carbon Innovation, SRK.**

Telkwa Mining contracted SRK to provide a scientifically defensible NPR criterion for segregating *non-PAG* material from PAG material for the planning/regulatory and operational verification phases based on site-specific data for the Tenas Deposit and best practices provided in the MEND (2009) prediction manual for drainage chemistry from sulphidic geologic materials.

SRK determined that a site-specific NPR cut off criteria of 1.20 for this deposit was appropriate to characterize blasthole rock as PAG (NPR less than 1.2) or *non-PAG* (NPR greater than or equal to 1.2). However, Telkwa Mining has elected to use a more conservative NPR criterion of 2.0 as a cut off versus the site-specific value of 1.20 to identify exploration drillhole and blasthole rock as PAG and non-PAG. This criterion was selected to ensure that Telkwa Mining will not classify PAG rock as *non-PAG rock*. This criterion will be reviewed as additional information is gathered for the permitting application at which point if the data supports it, Telkwa Mining will apply to revise the proposed NPR criterion.

The following provides a clear definition for the NPR cut off criterion used for the Tenas Project.

Planning, Regulatory, and Operational Stages

For mine planning processes, regulatory submissions such as the EAC application and operational verification testing, an NPR cut off criteria of 2.0 will be used to segregate *non-PAG* from PAG in exploration drillhole and/or blasthole. All rock with an NPR value less than 2.0 will be designated as PAG while rock having an NPR >= 2.0 will be classified as *non-PAG* based on verification testing specified in the ML/ARD management plan attached in **Appendix 17: Metal Leaching/Acid Rock Drainage Management Plan, SRK**.

Non-rock materials such as surface soils, overburden, processed coal, processed rock, and run-of-mine coal were characterized as PAG or *non-PAG* also using a cut-off of 2.0.

The justification to use an NPR cutoff of 2.0 for the planning, regulatory submission and operational stages for rock and non-rock materials is based on other deposits in BC, and an understanding of the site-specific geochemical information for this Project. The NPR criterion of 2.0 is also supported by the static geochemical testing results which showed that positive correlation of calcium and magnesium to the modified-NP indicating carbonate minerals are available to neutralize acid production (SRK 2024b).In addition, as noted above, kinetic testing results (SRK 2024b) indicate that an NPR of 1.2 is sufficient to identify rock as PAG or *non-PAG*. Selection of an operational NPR greater than the site-specific value is therefore suitable for identifying rock as PAG or *non-PAG*.

FOLLOWUP COMMENTS

LETTER IR 140, 142, 143, 146, and 145, AND 140b ITT TABLE

To address overestimation of available NP, please specify the best-fit linear regression of the data in Figure 8 and do not fix the line through the origin. A review of Figure 8 of Appendix 1.0-M that illustrates the relationship between TIC-Fe Corrected and Modified NP also indicates that the Modified NP may on occasion overestimate available NP and as a result, revising the NPR criterion to the minimum NPR cut-off value of 1.2 may result in PAG rock being managed as Non-PAG mine rock.

a) *Provide a greater range of percentile values in Table 2-4 and provide discussion of how spatially extensive a full PAG interval would be encountered for each zone in the pit.*

Regulatory Clarification provided via email from Morgan Dyas on February 9th, 2024

The request to "provide a discussion of how spatially extensive a full PAG interval would be encountered for each zone in the pit" is based on the implications stemming from the statement in Appendix 1.0 M (SRK, 2022) that a unit is NPAG based on an average NPR > 1.2. The characterization results indicate that the Tenas Project geologic units contain both PAG and NPAG strata. For example, more than 10 of the 20 boreholes that intersected Unit 5 have NPR < 1.2, thus over ½ of the strata in this unit is PAG. By stating that overall a unit is NPAG implies that the mixing and blending associated with the standard mining procedures of a unit will prevent localized ARD from forming within a waste rock pile. To prevent localized ARD, published blending studies (Andrina, 2009; Mehling, 1998) indicate that blended quantities greater than 1:1 are required. This could not be achieved for Unit 5 without active management and may be difficult for units such as Unit 6 or Unit 7 that have median NPR of 1.7 and 1.6, respectively.

An understanding of the spatial distribution of PAG and NPAG within a stratigraphic unit would be required to allow effective blending to occur. The request to provide the spatial distribution of PAG strata was to determine if there is currently enough data to support that units designated as NPAG could actually be handled and placed as NPAG. Handling the entire zone for units 1a, 2/3, 5,55 and 6 as PAG and placing them in permanent flooded storage the average thickness and aerial map extent of each unit within the pit limits is adequate. However, if another type of PAG management is considered, more detailed characterization and identification of NPAG zones would be requested.

Information required for units 1 and 4 where NPAG is proposed to be segregated from PAG provide a map with average thickness and extent of the PAG and NPAG zones within the pit limits and show data points that were used to define the zones. This information would be helpful to inform additional characterization that may be required to allow segregation decisions to be made during permitting and/or operations.

RESPONSE 140b ITT TABLE

SRK has provided responses to this geoscience IR in **Appendix 18: Tenas Project Information Request Responses Related to Geotechnical Aspects, SRK**.

To clarify, SRK (2022) does not state that zones whose bulk properties are *non-PAG* will be mined as *non-PAG*. SRK (2022) states that all zones contain both PAG and *non-PAG* zones. The classification on the bulk properties was completed to provide an estimate of the *non-PAG* and

PAG quantities for the purpose of mine planning. As described in the ML/ARD Management Plan, verification will be conducted for *non-PAG* zones and separable PAG intervals in *non-PAG* zones will be segregated and submerged in the management ponds, in the same manner as rock from zones that were characterized as PAG based on their bulk quantities.

Telkwa Mining has stated that no blending is occurring for *non-PAG* units on a horizontal aerial basis to achieve a higher NPR, rather *non-PAG* areas will not be placed underwater while PAG areas will be placed underwater. The only blending that will occur is within the vertical horizon of a mining bench of 12 meters which is expected to occur from drilling/blasting and mining activities within the dig face.

Figure 2-17 shows how Zone 5 would be segregated if verification testing agreed with the exploration drillhole polygons and an NPR cut-off of 2.0 was used with blocks in green being treated as *non-PAG* while blocks in red and yellow are treated as PAG. The above methodology follows a very similar and proven process used in metal mines to designate ore from mine rock, with this Project is using it to designate PAG from *non-PAG* rock. However, in the EAC Application the entire Zone 5 was classified as PAG and placed underwater. The same exercise could be completed using a different NPR criterion value if Telkwa Mining were successful in amending the NPR value of 2.0 being used in the EAC application.

Zones 5 and 6 are both entirely placed underwater in the EAC application so there is currently no segregation of polygons above an NPR of 2 versus below 2 so the statement above is not applicable to the EAC application. As stated earlier, Zones 7 and 8 are not mined within the EA open pit so the reference to Zone 7 above is not relevant to this application, however it would be subject to the same verification testing as other zones if it were to be encountered and to be treated as non-PAG.

Figure 2-18 and **Figure 2-19** illustrate how zones 1, and 4 were split into PAG and *non-PAG* zones for the EAC application using a cut off of 2.0. Polygons coloured in red and yellow were treated as PAG while polygons colored green were treated as *non-PAG*.

The methodology proposed is like that used to define ore and non-ore at a metal mine based on the blastholes and blending is currently not planned to occur.

FOLLOWUP COMMENTS

142 ITT Table

Carbonate molar ratio (CMR) is a critical assessment because it has implications on estimates for the time to onset of ARD, the volume of PAG rock that requires management and the design of the ARD management facilities at site. As noted in the TCL response, the flattening of the CMR vs. sulphate trend shown on Figure 14 represents the minimum NPR cut-off as the CMR evaluation does not account for other factors that need to be accounted for when assigning NPR criteria such as NP availability and other factors as outlined in MEND 2009 ARD Prediction Manual. It is the opinion of the reviewer that assigning a NPR cutoff criteria solely based on the CMR and not taking into account other factors that may affect the on-set of ARD, such as available NP, is not supported by the presented data and contributing factors at a mine scale. This comment is related to Comment #140 #143, and #146.

FOLLOWUP COMMENTS

FOLLOW UP 143 ITT TABLE

EMLI understands that the average weighted NPR of 1.2 did not account for other factors that may affect the onset of ARD, such as blended PAG and non-PAG strata in an unsaturated embankment or pile. EMLI understands that the NPR cutoff of NPR = 1.2 did not account for other factors that may affect the onset of ARD, such as available NP. The proponent should therefore provide an extended evaluation of these other factors if they wish to apply for an average

weighted NPR less than 2.0. Until this demonstration is done the Proponent should use a uniform approach based on NPR criterion of 2 to designate zoning of material as PAG or non-PAG and ensure their ML ARD management plan is updated accordingly.

OVERVIEW IR LETTER

The geochemical characterization report defines non-PAG material based on weighed NPR of 1.2. If the application of a weighted average NPR of 1.2 to define non-PAG and PAG zones is not conservative, it may impact the quantity of PAG waste rock to manage and configuration of the project during the life of mine. Additional information should therefore be presented by the proponent to demonstrate the conservativeness of this approach.

- *EMLI understands that the neutralization potential ratio (NPR) cutoff of NPR = 1.2 did not account for other factors that may affect the on-set of acid rock drainage (ARD), such as available NP blended PAG and non-PAG strata in an unsaturated embankment or pile. An evaluation of these other factors with an average weighted NPR less than 2.0 was not provided.*

LETTER IR 143 AND 143 ITT TABLE

EMLI understands that the weighted NPR cutoff of NPR = 1.2 to define non-PAG zones 5, 55, and 6. This did not account for other factors that may affect the on-set of ARD, such as available NP blended PAG and non-PAG strata in an unsaturated embankment or pile.

1. *Provide an extended evaluation of these other factors if an average weighted NPR less than 2.0 is applied.*
2. *Provide a demonstration of the conservativeness of application of an average weighted NPR of 1.2*

RESPONSE 143 ITT TABLE

SRK has provided responses to this geoscience IR in **Appendix 18: Tenas Project Information Request Responses Related to Geotechnical Aspects, SRK**.

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

The metal leaching potential of overburden may not be driven by the same processes as sulphidic mine rock ARD and as a result, basic static testing [e.g., acid base accounting (ABA) and metal content] alone may not quantify the risk associated with overburden. The proposed geochemical characterization and monitoring program must also include testing methods to assess the metal leaching potential.

LETTER IR 145 AND 145 ITT TABLE

Conduct a geochemical characterization and monitoring program using methods to assess the ML potential.

a) Specify what additional methods will be employed as part of the geochemical characterization and monitoring program to characterize the metal/contaminant leaching potential at the expected pH of the material on the mine site.

b) b) Evaluate the metal/contaminant leaching potential and duration at the expected pH from the samples already collected to characterize the overburden.

RESPOSNE 145 ITT TABLE

SRK has provided responses to this geoscience IR in **Appendix 18: Tenas Project Information Request Responses Related to Geotechnical Aspects, SRK**.

FOLLOWUP COMMENTS

Follow up to 146 ITT Table

Please propose a more conservative development of the Tenas mine rock NP designation and the ARD criterion of NP/AP = 1.2 based on responses to comments EMLI 140, 142 and 143.

LETTER IR 140, 142, 143, 146, and 145, AND 140b ITT TABLE

a) *Propose a more conservative development of the Tenas mine rock NP designation and the ARD criterion of NP/AP = 1.2.*

EMLI Clarification provided on April 18, 2024

The EMLI request is requesting the proponent to determine a more conservative approach to define PAG strata for the Tenas Project. The request is based on the individual IRs provided in the Round 2 EMLI Geoscience IRs 140, 142, 143 and 146. The request may be fulfilled by revising the approach to calculate available NP and/or revising the NP/AP criterion for PAG strata. It may be best summarized by point 3 of IR 143 outlined below.

SRK has provided responses to this geoscience IR in **Appendix 18: Tenas Project Information Request Responses Related to Geotechnical Aspects, SRK**.

Telkwa Mining contracted SRK to provide a scientifically defensible NPR criterion for segregating *non-PAG* material from PAG material for the planning/regulatory and operational verification phases based on site-specific data for the Tenas Deposit and best practices provided in the MEND (2009) prediction manual for drainage chemistry from sulphidic geologic materials.

SRK determined that a site-specific NPR cut off criteria of 1.20 for this deposit was appropriate to characterize blasthole rock as PAG (NPR less than 1.2) or *non-PAG* (NPR greater than or equal to 1.2). However, Telkwa Mining has elected to use a more conservative NPR criterion of 2.0 as a cut off versus the site-specific value of 1.20 to identify exploration drillhole and blasthole rock as PAG and *non-PAG*. This criterion was selected to ensure that Telkwa Mining will not classify PAG rock as *non-PAG* rock. This criterion will be reviewed as additional information is gathered for the permitting application at which point if the data supports it, Telkwa Mining will apply to revise the proposed NPR criterion.

The following provides a clear definition for the NPR cut off criterion used for the Tenas Project.

Planning, Regulatory, and Operational Stages

For mine planning processes, regulatory submissions such as the EAC application and operational verification testing, an NPR cut off criteria of 2.0 will be used to segregate *non-PAG* from PAG in exploration drillhole and/or blasthole. All rock with an NPR value less than 2.0 will be designated as PAG while rock having an NPR >= 2.0 will be classified as *non-PAG* based on verification testing specified in the ML/ARD management plan attached in **Appendix 17: Metal Leaching/Acid Rock Drainage Management Plan, SRK**.

Non-rock materials such as surface soils, overburden, processed coal, processed rock, and run-of-mine coal were characterized as PAG or *non-PAG* also using a cut-off of 2.0.

FOLLOWUP COMMENTS

FOLLOWUP COMMENTS LETTER IR 153 AND 153 ITT TABLE

EMLI understands that precipitation of these mineral phases, and the predicted concentrations, will be validated through operational water quality monitoring.

1. *Specify how the minerals or other attenuation processes identified through speciation modelling will be confirmed by mineralogical or geochemical characterization of the material.*

RESPONSE 153 ITT TABLE THEME #1

SRK has provided responses to this geoscience IR in **Appendix 18: Tenas Project Information Request Responses Related to Geotechnical Aspects, SRK**.

FOLLOWUP COMMENTS

LETTER IR 153 AND 153 ITT TABLE

2. *Describe the field or laboratory studies that will be conducted to validate these assumptions (e.g., field barrel program).*

RESPONSE 153 ITT TABLE THEME #2

Telkwa Mining initiated a field barrel program in October of 2019 and includes a discussion of the available results up to October 2023 which is four years of data. The report is provided in **Appendix 3: Geochemical Field Barrel Results Interpretation, SRK**. Key findings of this program are:

- After four plus years of testing only one barrel has gone acid using material from the drill program.
- Source terms for some parameters were updated in the Final EAC Project Case (2024) to reflect what the monitoring has shown to date.

Telkwa Mining will continue monitoring the barrel samples for the foreseeable future with SRK providing a follow up analysis every 2 to 3 years.

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

Additional sensitivities are needed to refine the water quality modelling predictions:

- *Exposed PAG rock in the management pond during a period of early closure;*
- *PAG rock exposures on pit wall;*
- *Upper-case prediction that is representative of challenging blasting conditions that could lead to higher nitrogen loading to blasted rock.*

LETTER IR 154, 157, AND 161 AND 154a ITT TABLE

1. *Prepare a sensitivity within the WLBM to evaluate how a 4-meter thickness of PAG rock left exposed in a management pond during a period of early closure would affect water quality.*
2. *Provide a sensitivity in the water quality model to allow PAG exposures on pit wall to understand how exposure of PAG may affect downstream water quality.*
3. *Develop an upper-case prediction that is representative of challenging blasting conditions that could lead to higher nitrogen loading to blasted rock.*

RESPONSE LETTER IR 154, 157, AND 161 AND 154a ITT TABLE

SRK has provided responses to this geoscience IR in **Tenas Project – Water and Load Balance Modeling Report (Updated 2025), SRK**.

FOLLOWUP COMMENTS

LETTER IR 154, 164 AND 154, 164 ITT TABLE

1. *Clarify what loading rates were used for developing mine rock source terms, including differences in Table 2-6 and Attachment 2 and Table A-4.*
2. *Provide annual non-PAG material quantities required to construct the embankments and the location of where this material will be sourced.*

RESPONSE LETTER IR 154, 164, AND 154, 164 ITT TABLE

SRK has provided responses to this geoscience IR in **Appendix 18: Tenas Project Information Request Responses Related to Geotechnical Aspects, SRK**.

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

EMLI understands that the App 13.5 reports that calcite precipitation is likely to occur in seepage from mine site facilities and in site water management ponds in varying degrees during operations, closure, and post-closure. However, predictions indicate that calcite precipitation is not expected to occur downstream of the proposed project footprint based on current observations and baseline concentrations. Additional information should be provided on:

- *The demonstration that calcite precipitation is not expected to occur downstream of the proposed project including all seepage and surface pathways.*
- *The mechanisms that might lead to calcite precipitation.*
- *Proposed calcite monitoring, management plan, and contingency measures to prevent or treat the onset of calcite precipitation downstream of the project discharge.*

174 LETTER IR AND ITT TABLE

EMLI understands that, based on the conclusions made in Appendix 13.5-K, calcite precipitation is likely to occur in seepage from mine site facilities and in site water management ponds in varying degrees during operations, closure, and post-closure. However, predictions indicate that calcite precipitation is not expected to occur downstream of the proposed project footprint based on current observations and baseline concentrations.

1. *What are the uncertainty and gaps around the current assessment that calcite precipitation is not expected to occur downstream of the proposed project footprint based on current observations and baseline concentrations? Please describe how the baseline observations and related conclusions relate to the projected load from the mine and propose recommendations to address these uncertainties and gaps.*
2. *Please update the calcite conceptual model provided in App 13.5K to include seepage pathways through groundwater or provide a rationale for its omission.*
3. *Provide clarifications on the mechanisms and likelihood of calcite precipitation in the immediate downstream environment including all pathways (i.e., surface and groundwater) below the end-of-pipe discharge location in Goathorn Creek.*
4. *Provide details of the calcite monitoring and management plan to prevent onset of calcite precipitation downstream of the project discharge and contingency measures to be implemented if specific triggers on the mine site are reached.*

RESPONSE 174 ITT TABLE

SRK has provided responses to this geoscience IR in **Appendix 18: Tenas Project Information Request Responses Related to Geotechnical Aspects, SRK**.

FOLLOWUP COMMENTS

175 ITT TABLE

EMLI is consulting with ENV on water quality monitoring and water management measures for this project. Telkwa Coal will need to propose conceptual design of management structures as part of the current application to demonstrate that the Project as proposed is capable of managing water not suitable for discharge and meeting WQGs.

176a ITT TABLE

EMLI understands that ENV's review of the surface water quality effects assessment and proposed water quality benchmarks is ongoing. EMLI notes that based on that review additional water quality mitigation for the Project may be required. Should water treatment or other mitigation measures be proposed for the Project, EMLI will review the information at that time. Telkwa Coal is encouraged to engage as soon as possible with EMLI on any proposed water treatment, especially if any passive or semi-passive technologies are proposed.

IR LETTER OVERVIEW

Additional conceptual design of alternative treatment options, mitigation measures, and management structures are needed to prevent the discharge of water that is not suitable for release to the environment.

LETTER IR 176 AND 176b ITT TABLE

1. *Provide conceptual design of alternative treatment options, mitigation measures, and management structures that can manage water not suitable for discharge and that meet BC WQGs.*

RESPONSE 176 ITT TABLE

This was previously addressed by IR **Theme 1 RESPONSE IR 175, 176b, 514, 350, 353, and 355** above.

Telkwa Mining believes the details above and the attached appendices address the requirements set forth in IR **Theme 7**.

THEME 8: EMLI GEOTECHNICAL CLARIFICATIONS

FOLLOWUP COMMENTS

IR LETTER OVERVIEW

The proponent does not identify the processed rock waste as tailings and does not identify the North, East, and West Management Ponds as tailings storage facilities (TSFs). As per the Health, Safety and Reclamation Code for Mines in British Columbia (the Code), the definition of "tailings" is: "the residue remaining from the preparation of a concentrate of minerals or coal;" and a "tailings storage facility" (TSF) is: "a facility that stores tailings." As per these definitions, the "processed rock" described in the Application is considered tailings and the North, East and West Management Ponds are TSFs.

- *TSFs have different minimum requirements than water dams in BC, including, but not limited to, minimum factors of safety, minimum design requirements for larger flood (return event and duration) and seismic events, downstream slopes, and many other requirements related to water management, performance, monitoring and surveillance, governance, etc.*

RESPONSE IR LETTER OVERVIEW

Telkwa Mining and SRK classified the management ponds as water holding ponds versus tailings storage ponds due to the following reasons:

- Embankment construction does not use tailing materials as a construction material but rather used engineered specified materials from mining activities;
- The ratio of PAG rock to processed rock (tailings) is approximately 11.25 to 1 on a volume basis so PAG rock will be the predominant material dictating performance of the materials contained within the embankment;
- Processed rock did not match definition of tailings provided by Vick; and,
- Processed rock is dewatered to less than 25% moisture prior to placement within the management ponds.

However, even though Telkwa Mining and SRK did not classify the management and control ponds as tailings storage facilities, due to the size of the management and control ponds, closeness to population centers such as the Village of Telkwa, and fish habitat Telkwa Mining/SRK utilized the guidelines for design requirements that matched the tailings pond design guidelines as these were the most conservative parameters to reference as summarized by **Table 2-23** below.

Table 2-23: Canadian Dam Association Guidelines for Design of Tailings Dams[1]

Dam Class	Annual Exceedance Probability - Floods[2]	Annual Exceedance Probability - Earthquakes	Minimum Static Factor of Safety			Downstream Slope No Steeper Than
			End of Construction	Long Term	Full or Partial Drawdown	
Low	1/3 between 1/975 and PMF	1/2,475	1.5	1.5	1.5	2H:1V
Significant	1/3 between 1/975 and PMF	1/2,475				
High	1/3 between 1/1,000 and PMF	1/2,475				
Very High	2/3 between 1/1,000 and PMF	½ between 1/2475 and 1/10,000 or MCE				
Extreme	PMF	1/10,000 or MCE				

Notes:

1. Adapted from CDA Dam Safety Guidelines, 2013. Further context and guidance provided there.
2. The Code required that a facility that stores the inflow design flood use a minimum event duration of 72 hours.

Source: BC MEMLI 2022

MCE=Maximum Credible Earthquake; PMF=probable maximum flood.

Telkwa Mining has adopted a more conservative approach to the design of the management ponds than is required for even some of the parameters for a Tailings Storage Facility (TSF).

For example, the Factor of Safety (FOS) that Telkwa Mining has put in place is 1.60 for all periods versus 1.50 provided in **Table 2-23** above and a downstream slope no steeper than 3H to 1V and an upstream slope no steeper than 2.5H to 1V versus 2H to 1V downstream requirement specified by **Table 2-23** above.

Given their proximity to the Village of Telkwa, the more stringent requirements of TSF embankments will be applied to management and control pond embankments regarding but not limited to the following parameters:

- minimum FOS;
- minimum design requirements for larger flood (return event and duration);
- seismic events;
- downstream and upstream slopes;
- water management;

- performance;
- monitoring and surveillance;
- governance;
- emergency response plan; and,
- etc.

Please find additional information on this IR provided in **Appendix 18: Tenas Project Information Request Responses Related to Geotechnical Aspects, SRK**.

LETTER IR 171 AND 171 ITT TABLE

The report FINAL Tenas Project Dam Breach Assessment Report dated April 2021, by SRK (Canada) Ltd., included as Appendix 1.0-AA of the Application, has not been appropriately sealed in accordance with Engineers and Geoscientists BC requirements. Provide appropriately sealed documents, as required, including the Dam Breach Analysis included as Appendix 1.0-AA of the Application.

RESPONSE 171 ITT TABLE

Please find attached **Appendix 19: Tenas Project Dam Breach Assessment Report, SRK**.

FOLLOW UP COMMENTS

IR LETTER OVERVIEW

Completion of an alternative means of undertaking the proposed project with respect to options for tailings management that considers technology, siting, and water balance has not been demonstrated.

LETTER IR 178 AND 178 ITT TABLE

Applications must include an alternatives assessment for the Management Ponds/Tailings Storage Facilities and the alternatives assessment completed should be consistent with the Guidelines for the Assessment of Alternative for Mine Waste Disposal.

1. Provide a detailed review of tailings storage alternatives assessed to support the proposed mine plan
3. Available from: https://www2.gov.bc.ca/assets/gov/environment/natural-resource-stewardship/environmental-assessments/guidance-documents/eao-guidance-tailingsmanagement.pdf
4 Available from: https://www.canada.ca/en/environment-climate change/services/managing-pollution/publications/guidelines-alternatives-mine-waste-disposal/chapter- 1.html

RESPONSE 178 ITT TABLE THEME #1

Based on the geochemical work conducted, processed rock has been classified as PAG material and as such placement of this material underwater is the recommended management strategy for this material to prevent potential ARD in the future. This was the conclusion of **Tenas Project PAG Management Alternative Means Assessment for managing this material, SRK**, provided by SRK with the EAC Application and included again as **Appendix 20: PAG Management Alternatives Assessment, SRK** with this response.

This requirement influences all future decisions with respect to this material, which is why this assessment was completed first. In response to this IR, SRK completed an **PAG Alternative Materials Storage Assessment** using the guidelines provided by Environment and Climate Change Canada *Guidelines for the Assessment of Alternatives for Mine Waste Disposal, July 2014* which is provided in **Appendix 21: Tenas Project Potential Acid Generating Material Storage Alternatives Assessment, SRK**. Based on the guidelines a multiple-stage process was completed as follows:

1. Step 1 involved completing a screening exercise to determine potential viable location for the storage of materials.
2. Step 2 involved completing a Multiple Accounts Analysis (MAA) for the identified preferred locations and configurations to identify the preferred option going forward.
3. Step 3 involved completing a sensitivity analysis to determine if the preferred option was robust enough to remain the preferred option under several conditions.

Figure 2-20 and **Figure 2-21** below illustrate the results of the MAA and sensitivity analysis which demonstrated that the option submitted in the EAC Application was the preferred option to carry forward into detailed design during the permitting phase of the Project.

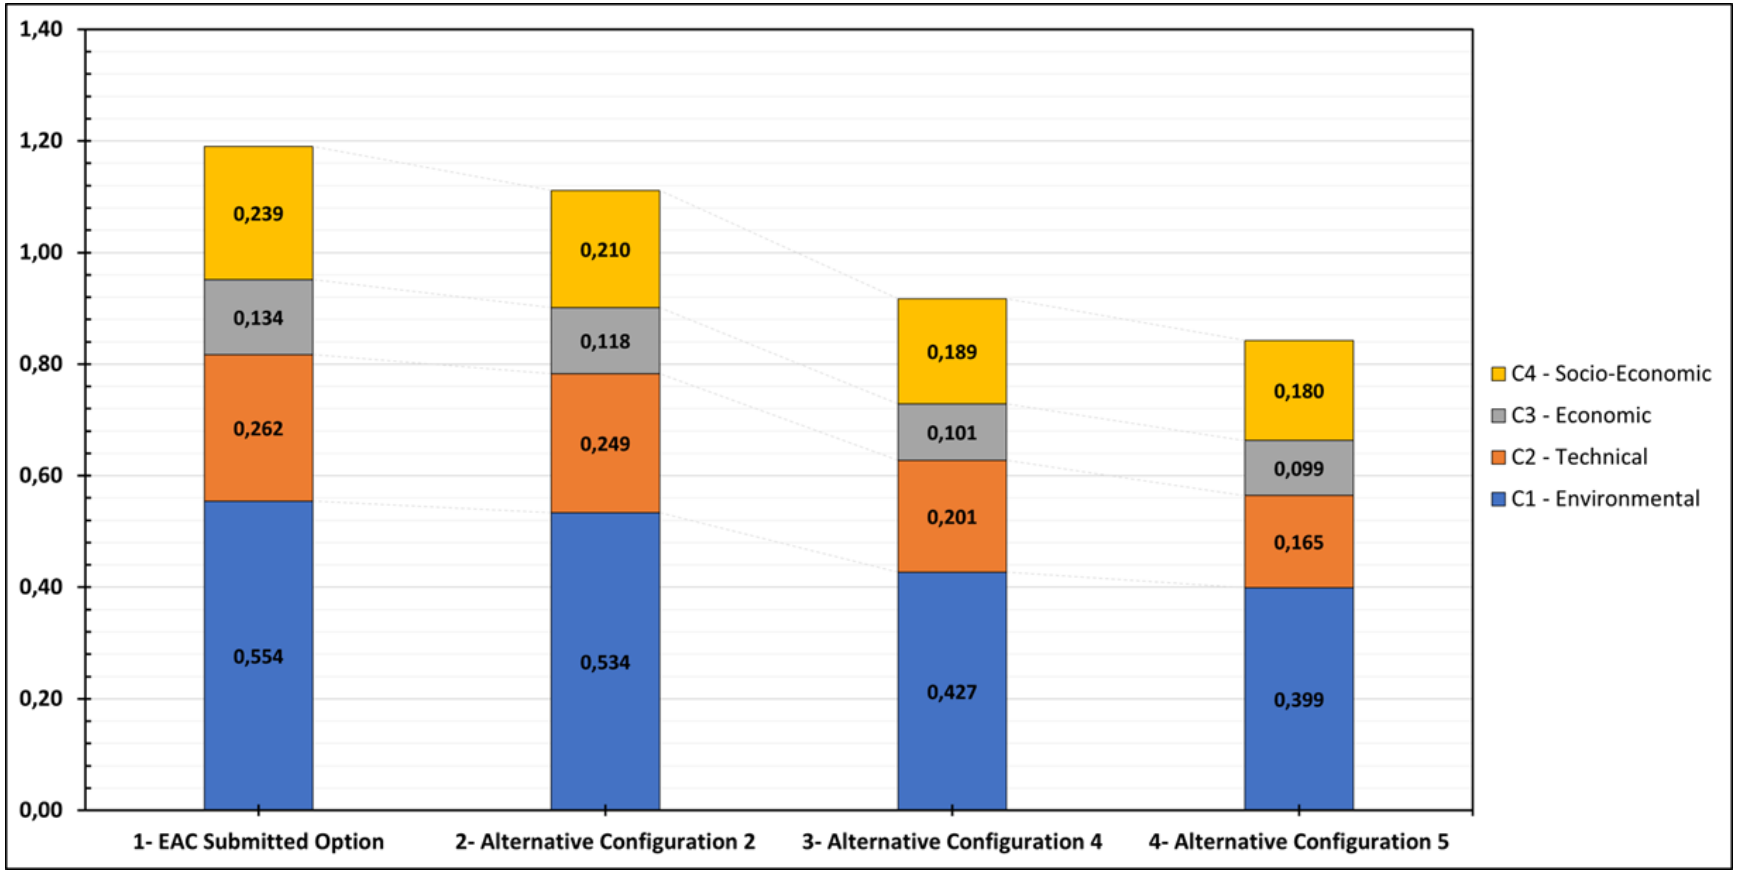

Figure 2-20: Multiple Accounts Analysis Results of the Final EAC Project Case (2024) Location versus Alternatives

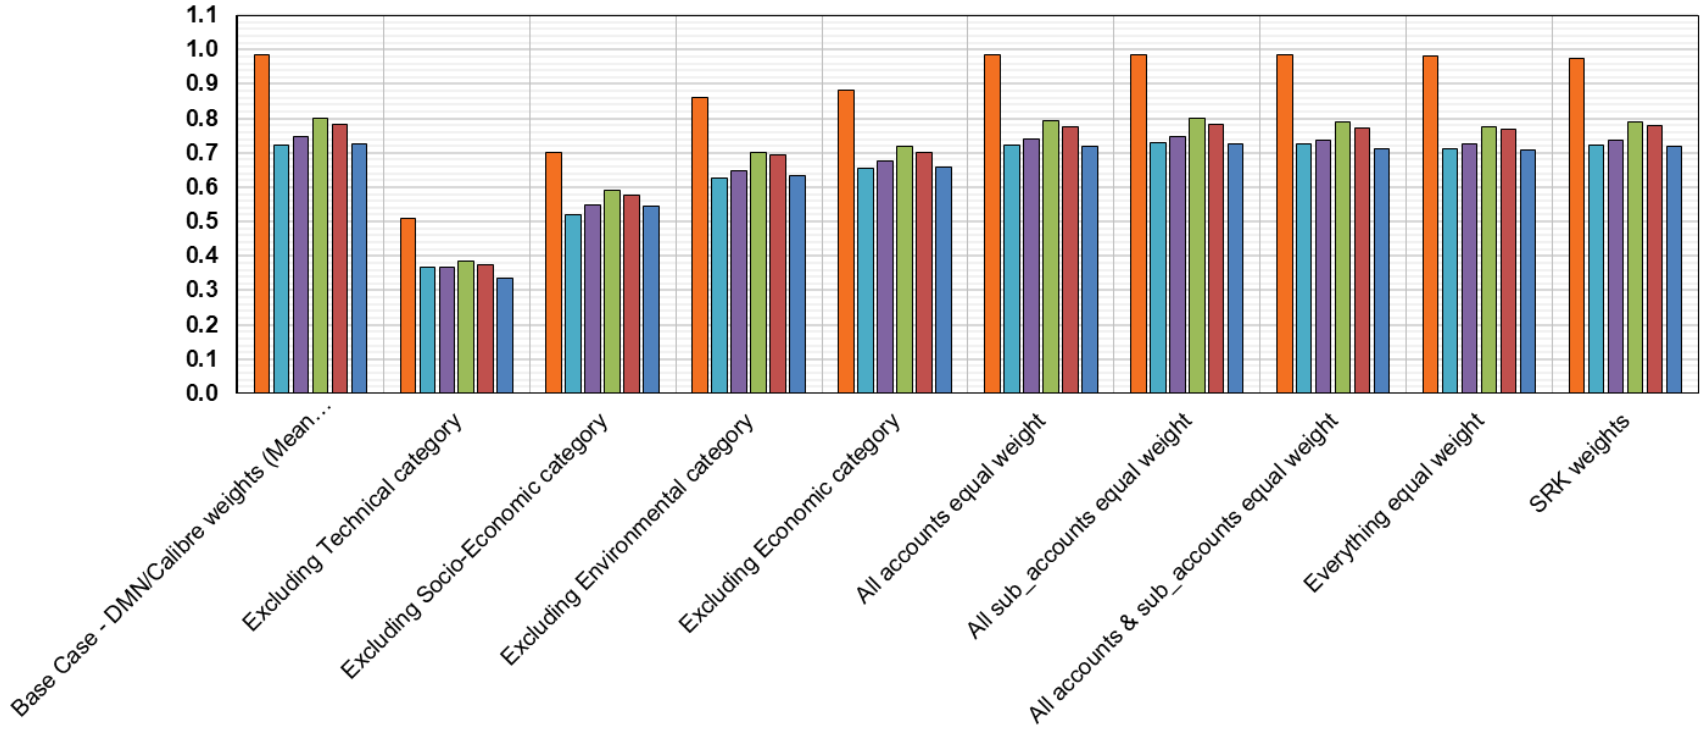

Figure 2-21: Multiple Accounts Analysis Sensitivity Results of the Final EAC Project Case (2024) Location versus Alternatives

Please find additional information on this IR provided in **Appendix 18: Tenas Project Information Request Responses Related to Geotechnical Aspects, SRK**.

FOLLOWUP COMMENTS

OVERVIEW LETTER IR

Results of the Dam Breach Analysis (DBA) does not clearly support the selected Consequence Classification Ratings for Dams or the seismic design criteria required by the Code given that the DBA reports that over 100 people could be impacted or at risk in the event of a breach of one of more of the management pond embankments. The Consequence Classification and seismic design criteria are lower than what is anticipated from the results of the Dam Breach Analysis, which could result in use of design criteria that are not consistent with regulatory requirements or accepted industry practice.

LETTER IR 181 AND FOLLOW UP 181 ITT TABLE

1. *Provide justification for the selection of the failure scenarios considered, including descriptions of the findings of all cascading failure modes/scenarios assessed.*
2. *Provide justification for selection of a "Very High" Consequence Classification given the findings of the Dam Breach Analysis that over 100 people could be impacted or at risk in the event of potential failure or breach of one or more of the management pond embankments.*
    a. *Include the relevant TSF regulations and guidelines that support this determination.*
    b. *Indicate what evaluation of possible environmental impacts due to the release of the contents of the North, West or East Management Ponds was used as a basis for selection of Consequence Classification. The environmental impacts should be consistent with the current understanding of the project (PAG tailings, etc.) and include appropriate references to the sources of information considered.*
3. *Provide justification for selection of the TSF design flood events (Inflow Design Flood and Environmental Design Flood). Include the relevant TSF regulations and guidelines that support this design event selection.*
4. *Provide justification for selection of an earthquake with a return period of 1 in 2,475 years for the Management Ponds/TSFs stability assessment. Include the relevant TSF regulations and guidelines that support this design event selection.*

RESPONSE FOLLOW UP 181 ITT TABLE

Please find additional information on this IR provided in **Appendix 18: Tenas Project Information Request Responses Related to Geotechnical Aspects, SRK**.

Telkwa Mining believes the details above and provided in attached appendices address the requirements set forth in IR **Theme 8**.

3. FIRST NATION FEEDBACK

The Office of the Wet'suwet'en (OW) provided comment on these submissions on February 28, and March 12, 2025, which are summarized in

Table 3-1 below. Responses have been provided in **Appendix 22 Tenas Project Information Request Responses from Office of the Wet'suwet'en – Final, SRK**.

Telkwa Mining is expecting further input could be provided from Wet'suwet'en during their Assessment Process. Where modifications or clarifications of responses are appropriate Telkwa Mining will provide supplemental information to both the EAO and OW.

Table 3-1: February 28, March 12, and May 15, 2025, Comments from OW

Comment ID	Master ITT Comment ID (BC EAO)	OW Comment from Feb 28 or Mar 12 Letters/Report	OW Recommendations from Feb 28 or Mar 12 Letters/Report
OW-011	175, 176, 307, 350, 353, 355, 356, 514	As mentioned, a presentation from TML is welcome. However, OW has its own priorities and objectives related to protecting aquatic resources in the territory. OW is working to identify Project-related issues related to water quality, water and load balance modeling, water treatment, and hydrology.	To address this IR, the Proponent should: • Provide all the information requested in OW's forthcoming responses to TML's IR responses. • Consider forthcoming information from OW regarding how all concerns related to Project impacts on aquatic resources have been identified and characterized. • Consider forthcoming information from OW regarding whether monitoring and mitigation plans are adequate to address adverse impacts to aquatic resources. Impacts to water may also be considered in the RIA being conducted by OW. This IR will remain open until OW is satisfied with how information from the RIA and the outcomes of OW's review of TML documents and engagement with TML on this issue are incorporated into Project monitoring, mitigation, and adaptive management plans.
OW-038	350 and 351	The Proponent provides 11 mitigation options (6 single treatment options and 5 that are combinations of 3 or more of the single treatment options) and models the results. The results show options for reduction of max monthly concentrations and reduction of WQG for Four Creek and Tenas Creek. All of the viable options for reduction include a combination of multiple treatments and would result in some periods of time of reduced downstream natural streamflow.	The Proponent provides viable options for reducing concentrations of selenium, sulfate, cadmium, and nitrate/nitrite including a combination of multiple treatments. In some cases (Table 9), exceedances still occur (e.g., selenium, nitrate) at the end of pipe, even when multiple treatments are applied, particularly from the Tenas Control Pond. While the right combination of mitigation treatments will definitely improve downstream water quality, there are impacts to local streamflow and in some cases other constituents (e.g., increases in selenium). The most concerning reductions in streamflow for both Tenas and Four Creek are during late summer months (August) and winter baseflows. It doesn't appear that these reductions in streamflow have been modelled within the Water Load Balance Model to predict how the lower flows will impact downstream WQ at prediction nodes, although reduced concentrations in surface and groundwater should help, reduced water flow could end up balancing that reduction and total constituent loading may ultimately not change much. This warrants further investigation. To resolve these issues, TML must: • Provide more information on how the reduction of water flow in the Tenas and Four Creek is involved in mitigations for reducing concentrations of selenium, sulfate, cadmium, and nitrate/nitrite; • Provide data for how this reduction is incorporated into the Water Load Balance Model to predict how the lower flows will impact water quality downstream, especially during late summer months (August) and winter baseflows; • Provide more information on the proposed water mitigations, including the reliability and risks of each option associated with failure of effective treatment, in addition to the expected beneficial change and the expected consequences of each treatment option;
OW-039	350 and 351	As above, the Proponent provides 11 mitigation options and describes aspects of treatment efficiency and effectiveness for each option, including modelled water quality outcomes. The Proponent provides information on the expected beneficial change and the expected consequences of each treatment option but does not provide risks associated with failure of effective treatment.	The reliability and risks of each option are not discussed, and very little information is provided on situations where the mitigation option may be less effective/ ineffective (i.e., high, or low run off conditions, liner failure, etc.). The water treatment plan option (Control 5) appears to be one of the most effective options, particularly when combined with other options. However, the design details of the water treatment plant have not been developed (which the proponent acknowledged in the document), and the reductions in constituent concentrations are only assumed. This would require additional storage and appropriate treatment rates, along with additional energy and waste disposal costs. As water treatment, in combination with other approaches, is the most effective way of reducing exceedances from the ponds, this option should be pursued but TML must provide more information on the details of that process (including detailed operations of the treatment facility over time, energy and water use, and efficiency of treatments, etc.). TML must provide further information on alternative treatment plans and outcomes that describe how the water treatment facility would be designed, what standards would be used, the operation, and the duration.
OW-040	356	The Proponent developed a new node (WQSEA1) of water quality measures for the Water and Load Balance Model (WLBM), 100 m downstream of the confluence with the unnamed tributary for Project discharge on Goathorn Creek. The Proponent developed and ran new WLBM scenarios to review the impacts of changes in seepage rates on expected water quality and says, "Water quality results will be presented at the new node (WQSEA1), WQS06, WQS05, WQS04, and WQS03_DS with the Final EA Water and Load Balance results". We have been unable to find the aforementioned document containing the results. There were some errors in the figure from the WLBM report (Fig 2.2-2.4 of App 4.3) that showed incorrect connections of the three creeks (Four	We are unable to find the documents containing the results of this IR response, "Final EA Water and Load Balance results", or Attachment IR 356-1 as the IR response does not provide further information regarding where these documents are located. We are unable to find any documents with that name in the review materials provided to us and therefore could not review the IR. Please provide these documents, including figures for each of the requested scenarios in the IR (Tributary receiving discharge above confluence with Goathorn Creek, and Goathorn Creek below confluence with tributary receiving discharge); projected water quality from baseline through to post-closure; and updated figures from the WLBM report (Fig 2.2-2.4 of App 4.3) that showed incorrect connections of the three creeks (Four Creek, Tenas Creek, Goathorn Creek).

Comment ID	Master ITT Comment ID (BC EAO)	OW Comment from Feb 28 or Mar 12 Letters/Report	OW Recommendations from Feb 28 or Mar 12 Letters/Report
		Creek, Tenas Creek, Goathorn Creek), but the proponent claims the errors in the figure were NOT incorporated into the model and that the model correctly accounts for the mixing of streams. There are final figures presented in Attachment IR 356-1; however, we also cannot find this document as the attachment with that name at the end of App F contains no information. We are also unclear whether this is the location of the other results the authors describe (e.g., figures for each of the requested scenarios and projected WQ from baseline through to post-closure). Because we were unable to locate this document, we could not completely review the response to the IR.	
OW-041	NEW	Same comment as previous. The Proponent developed a new node (WQSEA1) of water quality measures for the Water and Load Balance Model (WLBM), 100 m downstream of the confluence with the unnamed tributary for Project discharge on Goathorn Creek. The Proponent developed and ran new WLBM scenarios to review the impacts of changes in seepage rates on expected water quality and says, “Water quality results will be presented at the new node (WQSEA1), WQS06, WQS05, WQS04, and WQS03_DS with the Final EA Water and Load Balance results”. We have been unable to find the aforementioned document containing the results. There were some errors in the figure from the WLBM report (Fig 2.2-2.4 of App 4.3) that showed incorrect connections of the three creeks (Four Creek, Tenas Creek, Goathorn Creek), but the proponent claims the errors in the figure were NOT incorporated into the model and that the model correctly accounts for the mixing of streams. There are final figures presented in Attachment IR 356-1; however, we also cannot find this document as the attachment with that name at the end of App F contains no information. We are also unclear whether this is the location of the other results the authors describe (e.g., figures for each of the requested scenarios and projected WQ from baseline through to post-closure). Because we were unable to locate this document, we could not completely review the response to the IR.	We are unable to find the documents containing the results of this IR response, “Final EA Water and Load Balance results”, or Attachment IR 356-1 as the IR response does not provide further information regarding where these documents are located. We are unable to find any documents with that name in the review materials provided to us and therefore could not review the IR. Please provide these documents, including figures for each of the requested scenarios in the IR (Tributary receiving discharge above confluence with Goathorn Creek, and Goathorn Creek below confluence with tributary receiving discharge); projected water quality from baseline through to post-closure; and updated figures from the WLBM report (Fig 2.2-2.4 of App 4.3) that showed incorrect connections of the three creeks (Four Creek, Tenas Creek, Goathorn Creek).
OW-042	NEW	The IR document says, "In summary, the background water quality inputs used in the EAC Project Case (August 2022) were monthly mean values while seasonal values are used in both the Updated and Final EAC Project Cases (2024)". However, in Appendix F, Section 4.18.2, SRK says "The EA WLBM used statistics from the full water quality baseline monitoring record, including the 50th percentile and 95th percentile for each stream. Monthly or seasonal background source terms were not used". This is relatively confusing as responses in the IR in different locations are providing different answers to the initial question. In Appendix F, they follow up by saying they generated new baseline statistics for the Final EAC Project Case (2024) based on updated data, including a new 50th percentile for the winter months and a 50th percentile for the "rest of the year" (May to October). They say the Final EA Water and Load Balance Report will include the seasonal source terms for background concentrations on the in-stream water quality conditions, so we assume this is the 50th percentile or the median. However, it is unclear if this will be presented as the main WQ prediction scenario or alternative assessment scenario(s). We were unable to locate the document referred to as Final EA Water and Load Balance Report to further review.	Reporting the use of different time scales is troublesome, especially in a region with high seasonal variability. The caching of all "open water" months into one "summer season" is not appropriate as there are very different climate and ecosystem processes influencing or influenced by spring vs summer vs fall water quality dynamics. The use of one seasonal value may be skewed by over-represented high or low values that occur during more months, and therefore not representative of periods exhibiting seasonally low or high values. Monthly values would be more appropriate to capture full seasonal variability. Please provide this information. In addition, we were unable to fully review this IR because we could not locate the referenced document "Final EA Water and Load Balance Report". Please provide this information.
OW-043	NEW	Some of the sedimentation ponds that discharge to the natural ground were not included as part of the WLBM in the EAC application (the proponent lists 6). Four of the ponds are lined with impermeable geomembrane liners or equivalent and the remaining 2 are unlined. They were not considered in the site water and load balance model when it was developed because: 1) they are geographically separate from the EA Open Pit, management and control ponds, and material storage pile water management systems, 2) they are small and manage very defined catchments with low flow rates compared to discharge from mine components through Tenas Control Pond, 3) TSS is the main POC for most of these ponds but some also include nitrogen species, 4) they are designed to produce TSS well below the BC (35 vs 50 ppm) requirement so deemed protective of aquatic environment, 5) the remaining pond doesn't discharge to the environment it gets pumped	The organization of various ponds and their connectivity, as well as the lack of data associated with each pond is an obvious source of confusion in the application. This theme arises in many comments throughout the proponent’s IR response. Discharges from sedimentation ponds (excluding Tenas Control Pond/North Management Pond and Rail Infrastructure Pond) are directed towards natural ground. The Proponent plans to convey this water along natural flow pathways to eventually reach downstream watercourses. Despite use of pumps and other structures for controlled release, there is risk of overflow and higher amounts of release during high rain events, which may increase downstream erosion potential. The Proponent must provide a clear map of the location and connectivity of each pond along with an associated table that includes all the requested information from the IR.

Comment ID	Master ITT Comment ID (BC EAO)	OW Comment from Feb 28 or Mar 12 Letters/Report	OW Recommendations from Feb 28 or Mar 12 Letters/Report
		to the Tenas Control Pond, and 6) they describe how they deal with material from the Explosive Magazine Pond.	
OW-044	NEW	The only discharge that will be directed into a stream is the Tenas Control Pond (and North Management Pond after closure). An IDZ study was prepared to evaluate discharge from Tenas Control Pond, which found that discharge would not be acutely toxic. This discharge was simulated in the Water and Load Balance Model to quantify the expected effect in streams. They do not reference the IDZ study used to evaluate discharge, so we were unable to review in the context of this IR. The Proponent ensures that when the ponds are discharging, they will be monitored on a “regular basis” (frequency not mentioned) and monthly when not discharging. Monthly monitoring proposed with various (3) "action steps" proposed to address WQ exceedances if they should occur. Some of these involve reactions to chemical parameter exceedances of BC WQG over a "period of months".	Note that an IDZ will not be considered during permitting without an adequate BAT assessment. Given that a new BAT assessment has been performed with alternative treatment options, the IDZ study would need to be redone to account for water quality differences derived from various different treatment options. The comment does not address the need to also evaluate cumulative effects around the IDZ. In addition, the proposed frequency of monitoring for exceedances is inadequate given the risk to downstream fish. These ponds will be monitored monthly to evaluate toxicity results against authorized limits for lethality of Rainbow Trout. If exceedances exist, a number of actions are proposed to reduce exceedance, but given the frequency of monitoring (monthly) and the amount of time required for implementation of the proposed actions, it is possible exceedances (and downstream negative effects) could persist for a substantial amount of time (months) before any resolution. This presents a considerable prolonged threat to fish and ecosystem health. TML must correct these discrepancies.
OW-045	520	There are no lentic (i.e., lakes or ponds) water bodies located in the near-field or far-field receiving environments of the Project.	The concern here is sedimentation and conversion of selenium species, so there may be opportunities for this in micro-lentic environments such as back channels and pool environments along the stream course, but according to the proponent in this local study and regional study region there are no lentic environments.
OW-046	176	Mitigation control scenarios are discussed and compared, including the pros and cons of expected changes in water quality. The most effective treatments for reduction of selenium and nitrate-nitrite in both control ponds are combinations of multiple mitigation strategies, many of which include the strategy of water quality treatment (listed as "mitigation control 5").There are no plans or outcomes developed that describe how the water treatment facility would be designed or operate, some of the benefits are based on assumed targets met through treatment.	However, there are no actual plans or outcomes developed that describe how the water treatment facility would be designed or operate, some of the benefits are based on assumed targets met through treatment. This is acceptable but should be fleshed out further, and it should be confirmed that these targets can actually be met if this is considered a feasible option. The Proponent is also assuming the water quality treatment would persist past the end of closure as the model shows results out to 2100. Additional information on water treatment facility is needed (design, standards, operation, and duration) and should not be assumed if this is considered as an option, in conjunction with other mitigation strategies (it is included on the list of combined best options). There are also effects on streamflow in Four and Tenas Creek, which should be explored more with the water load balance model. Goat Creek was not included in the model outputs, although this is acknowledged by the authors. Impacts on Goat Creek should be included in additional assessment of further mitigation strategies.
OW-047	154, 157, 161	The Proponent claims that the evaluation of how a 4-meter thickness of PAG left exposed in a management pond would affect water quality is not possible because of the way the pumping system is set up and that the management ponds are always built ahead of PAG placement to ensure that the PAG is below water level. We are concerned that the Proponent dismissed this request saying that under properly managed scenarios this would not be a concern. "	We are concerned that the Proponent dismissed this request saying that under properly managed scenarios this would not be a concern. However, it doesn't provide information on the effects of exposed PAG to water quality under scenarios where the management pond techniques fail, such as failure of a pond dam or failure of the pumping system to work as designed. The Proponent must provide this information and include scenarios in the water quality model for estimating impacts where management actions fail, to provide a clear picture of the downstream impacts of PAG under less-than-ideal conditions, but conditions that could possibly occur if there are situations where proper management cannot occur (failure of pumping system or pond dam, or some other instance where a 2m cover of water cannot be maintained).
OW-048	154, 157, 161	It is unclear where the information is associated with this IR. Within App D they cite a ""SRK 2024a"" (page 16) with the results of the model output using the various source terms but the reference is not included at the end of the document under ""References"". Appendix A- Water Balance Report. contains source terms but has not been updated to include a sensitivity like requested in the IR.	We were unable to review this IR responses as we were unable to find the supporting information. Please provide this information.
OW-049	174	The predictions provided in SRK (2022d) indicate that calcite is not expected to form in downstream tributaries since predicted alkalinity, calcium and magnesium concentrations are like existing conditions and there is currently no visual evidence of calcite precipitation even though surface water in these drainages is supersaturated with respect to calcite under baseline conditions. Because of this, they suggest that site-specific Saturation Indices (SI) may need to be developed once sufficient monitoring data are available. They describe how if calcite formation is identified as part of the operational monitoring program, TML will develop a mitigation plan that will be submitted to EMLI for approval. The most common calcite prevention mitigation strategy is	1. The response to the IR states that the estimated SI do not suggest calcite precipitation, but detailed discussion is not in the reference. They do not specify what additional monitoring data is required for site-specific calculation of site-specific SIs for calcite. Is TML referring to monitoring data from this post-project operations, or baseline data? It is unclear where in the referenced SRK (2022d) document they specifically address calcite, as the term “calcite” only appears once in the document. TML must update the Discharge Management Plan and provide further information on how operation and a post-closure increase in conductivity in ponds and the receiving environment will affect the SI for calcite and predictions for precipitation. 2. Higher pCO2 in groundwater will be more likely to precipitate calcite at possible groundwater seepage locations (contact with atmosphere). Some accounting for this should be included in the conceptual model.

Comment ID	Master ITT Comment ID (BC EAO)	OW Comment from Feb 28 or Mar 12 Letters/Report	OW Recommendations from Feb 28 or Mar 12 Letters/Report
		addition of antiscalant to site effluent. This would be the most likely mitigation strategy should it be required. They also say there is no need to include groundwater seepage in the conceptual model as there is no reason for CO2 off-gassing to occur along groundwater pathways at the Project, and calcite is therefore not expected to precipitate in groundwater pathways.	3. Within the referenced SRK 2022d (Tenas Project Water and Load Balance Modeling Report REV1), we cannot find discussion of calcite precipitation, including mechanisms, contributing factors, predictions, etc. The response to the IR states that the estimated SI do not suggest calcite precipitation, but detailed discussion on this topic is not in the reference. According to the IR response, "predictions provided in SRK (2022d) indicate that calcite is not expected to form in downstream tributaries since predicted alkalinity, calcium and magnesium concentrations are like existing conditions". However, there are multiple examples of increases in alkalinity and magnesium (in particular) in the load model. Therefore, TML must explore conditions in terms of potential for calcite precipitation. 4. There is no plan, other than including calcite in the surface water quality monitoring program. If calcite formation is observed, then they will develop a mitigation plan. This plan will likely include mitigation using antiscalants. The proponent does not discuss this option further but should include considerations and possible impacts and interactions of the use of antiscalant for reducing calcite precipitation considering the high background conditions of aluminum in these watersheds.
OW-050	181	The statement "The effect of the rainy-day breach on aquatic habitat is low given the PMF/Q200 conditions already present" is not supported given the discharge at the mouth of Tenas Creek is estimated to be 1100 m^3/s in comparison to a PMF of 168 m^3/s, and that maximum water velocity and rate of discharge increase from a flood wave are not accounted for. However, we do agree that the risk to aquatic life for a breach of the East Dam or West Dam should be 'Very High' due to the likelihood of major long-term deterioration of critical steelhead spawning habitat. We believe that the 'Very High' classification would be more appropriate for a breach of the North or Tenas Dams as well given the likelihood of major long-term deterioration of critical steelhead spawning habitat in Tenas and Goathorn Creeks.	Given the likelihood of major long-term deterioration of critical steelhead spawning habitat in Tenas and Goathorn Creeks, a 'Very High' risk classification should be used for a breach of the North Dam or Tenas Dam.
OW-118	NEW	To help OW better assess how TML is protecting the Environmental Flow Needs, provide details on how and/or TML will manage flows to avoid high risk levels and maintain environmental flow needs (reduction of <10% of mean average by season) during operation. To help OW better assess how TML is protecting the Environmental Flow Needs, provide details on how and/or TML will manage flows to avoid high risk levels and maintain environmental flow needs (reduction of <10% of mean average by season) during operation.	Commit to appropriate planning for contaminant areas, which requires a proactive approach to mitigating contaminant leakage (rather than attempting to mitigate once problems have been identified);
OW-120	NEW	To help OW better assess how TML is protecting the Environmental Flow Needs, provide details on how and/or TML will manage flows to avoid high risk levels and maintain environmental flow needs (reduction of <10% of mean average by season) during operation. To help OW better assess how TML is protecting the Environmental Flow Needs, provide details on how and/or TML will manage flows to avoid high risk levels and maintain environmental flow needs (reduction of <10% of mean average by season) during operation.	Consider the appropriateness of water and load balance models and correct seepage migration rates and timing of peak contaminant concentrations;
OW-122	NEW	For Surface Water, Ground Water, and Aquatic Resources VCs, TML must:	Provide the cited document in Appendix D: "SRK 2024a" (page 16), which is missing from the end of the document under "References". Appendix A- Water and Load Balance Model Report.
OW-123	NEW	For Surface Water, Ground Water, and Aquatic Resources VCs, TML must:	Update the Discharge Management Plan - Calcite Precipitation document to include: • How operation and a post-closure increase in conductivity in ponds and the receiving environment affect the Saturation Indices (SI) for calcite, and predictions for precipitation; • Accounting for higher pCO2 in groundwater, which is more likely to precipitate calcite; • Further accounting for increased calcite precipitation in instances where alkalinity and magnesium in the water increase; and • A separate calcite monitoring and management plan, which considers possible impacts and interactions of the use of antiscalants for reducing calcite precipitation, considering the high background conditions of aluminum in these watersheds.
OW-124	NEW	For Surface Water, Ground Water, and Aquatic Resources VCs, TML must:	Provide additional information and figures for the Water and Load Balance Model Report that we have not been able to locate, including: • Final figures presented in "Attachment IR 356-1 as the attachment with that name at the end of App F contains no information;

Comment ID	Master ITT Comment ID (BC EAO)	OW Comment from Feb 28 or Mar 12 Letters/Report	OW Recommendations from Feb 28 or Mar 12 Letters/Report
			• Figures for each of the requested scenarios in the IR (Tributary receiving discharge above confluence with Goathorn Creek, and Goathorn Creek below confluence with tributary receiving discharge) and projected water quality from baseline through to post-closure; • Updated figures from the WLBM report (Fig 2.2-2.4 of App 4.3) that originally showed incorrect connections of the three creeks (Four Creek, Tenas Creek, Goathorn Creek); and • TML's response to the IR, labelled "Final EA Water and Load Balance results", or Attachment IR 356-1.
OW-125	NEW	For Surface Water, Ground Water, and Aquatic Resources VCs, TML must:	Use climate change predictions in the understanding of potential impacts throughout the operation and post-closure periods (e.g., changes in flow and changes in stream temperature due to changes in flow and air temperature).
OW-126	NEW	For Surface Water, Ground Water, and Aquatic Resources VCs, TML must:	Resolve outstanding technical questions regarding PAG Rock management and seepage including: • If PAG rock is to be submerged prior to the onset of ARD/ML, why would seepage tailings facilities contain the products of ARD/ML? • How much seepage is expected out of tailings facilities, both in groundwater and in surface water?

4. CLOSING

Thank you again for providing Telkwa Mining with the opportunity to respond to the Water Quality IRs from ENV and MEMLI. Telkwa Mining believes the responses provided close out the information requests that fall under Items 1 through 8. If there are any further questions or concerns, please do not hesitate to contact me.

Sincerely Yours,

Daniel J. Farmer, P.Eng.

Subject Tenas Project Information Request Responses from Office of the Wet'suwet'en - Final

The following memorandum presents SRK's responses to Information Requests (IRs) from the Office of the Wet'suwet'en related to the Tenas Project.

In addition to addressing these IRs, SRK has completed a series of updates to the water and load balance model (WLBM) for the Tenas Project since 2022, including the following:

- Review and updates to water quality guidelines, used for screening of water quality modeling results and identification of potential effects.
- Review and update the Tenas Project climatic records, based on additional data from the local station since the development of the EA baseline report (SRK 2025a).
- Review of streamflow model performance against measurements collected in 2022, along with implementation of an alternative dynamic streamflow model.
- In addition to climate records and streamflows, the climate change model has been updated to match current approved scientific requirements. All three updates are summarized in the updated hydrometric report (SRK 2025a).
- Updated background source terms incorporating seasonality (summer and winter conditions) in the model (SRK 2025b)
- Update of source terms related to barrel monitoring undertaken over the past four years which was used for quality predictions as provided in SRK 2024a.
- Update of source terms related to the non-PAG backfill to account for methodology of constructing this dump in lifts from the bottom up and progressive reclamation through the addition of overburden and surface soil (topsoil) covers as provided in Okane 2024.
- Review and update to the groundwater model which led to updated calculations to estimate the load in the creeks through groundwater seepage from the Project (SRK 2024b).

The updated water quality model is referred to in this document as the Final EAC Project Case (2024). Results for the updated water quality model can be found in the Updated Water and Load Balance Model report (SRK 2025b).

1 Responses to Information Requests

The following sections present SRK's responses to information requests (IRs) concerning the Tenas Project issued by Office of the Wet'suwet'en.

1.1 IR#OW-011

1.1.1 Information Request

As mentioned, a presentation from TML is welcome. However, OW has its own priorities and objectives related to protecting aquatic resources in the territory. OW is working to identify Project-related issues related to water quality, water and load balance modeling, water treatment, and hydrology.

To address this IR, the Proponent should:

• Provide all the information requested in OW's forthcoming responses to TML's IR responses.

• Consider forthcoming information from OW regarding how all concerns related to Project impacts on aquatic resources have been identified and characterized.

• Consider forthcoming information from OW regarding whether monitoring and mitigation plans are adequate to address adverse impacts to aquatic resources. Impacts to water may also be considered in the RIA being conducted by OW.

This IR will remain open until OW is satisfied with how information from the RIA and the outcomes of OW's review of TML documents and engagement with TML on this issue are incorporated into Project monitoring, mitigation, and adaptive management plans.

1.1.2 Response

TML acknowledges the comment. Please see complete response and figures/tables to this comment in the SRK memo [Tenas Project Information Request Responses from Office of the Wet'suwet'en memo, SRK June 2025] Attachment OW-011-1.

Please see responses to OW-38 through OW-50.

As requested by OW, TML will discuss appropriate incorporation of the results of forthcoming information related to water quality into Project design, monitoring, mitigation, and adaptive management plans.

1.2 IR# OW-038 (IR350 and 351 Section 3, Section 4)

1.2.1 Information Request

The Proponent provides viable options for reducing concentrations of selenium, sulfate, cadmium, and nitrate/nitrite including a combination of multiple treatments. In some cases (Table 9), exceedances still occur (e.g., selenium, nitrate) at the end of pipe, even when multiple treatments are applied, particularly from the Tenas Control Pond.

While the right combination of mitigation treatments will definitely improve downstream water quality, there are impacts to local streamflow and in some cases other constituents (e.g., increases in selenium). The most concerning reductions in streamflow for both Tenas and Four Creek are during late summer months (August) and winter baseflows. It doesn't appear that these reductions in streamflow have been modelled within the Water Load Balance Model to predict how the lower flows will impact downstream WQ at prediction nodes, although reduced concentrations in surface and groundwater should help, reduced water flow could end up balancing that reduction and total constituent loading may ultimately not change much. This warrants further investigation. To resolve these issues, TML must:

- Provide more information on how the reduction of water flow in the Tenas and Four Creek is involved in mitigations for reducing concentrations of selenium, sulfate, cadmium, and nitrate/nitrite;
- Provide data for how this reduction is incorporated into the Water Load Balance Model to predict how the lower flows will impact water quality downstream, especially during late summer months (August) and winter baseflows;
- Provide more information on the proposed water mitigations, including the reliability and risks of each option associated with failure of effective treatment, in addition to the expected beneficial change and the expected consequences of each treatment option.

Additionally, TML has not adequately considered how these concentrations will be impacted by the reductions in streamflow for both Tenas and Four Creek during late summer months (August) and winter baseflows. This is extremely concerning to OW, and Wet'suwet'en members have expressed that the water levels in the area are already low, and the Project will be impacting this even more.

1.2.2 Response

TML acknowledges the comment. Please see complete response and figures/tables to this comment in the SRK memo [Tenas Project Information Request Responses from Office of the Wet'suwet'en memo, SRK June 2025] Attachment OW-011-1.

This IR response was divided in two parts, addressing first the request for more information on how the reduction of flows in Tenas and Four Creeks is accounted for in the model, then providing more information on the mitigation measures and best management practices considered in the Best Achievable Technology Assessment.

Additional Information about Reduction of Flows in Tenas and Four Creeks

SRK has completed an extensive update to the Water and Load Balance Model since 2022 which is provided in Attachment OW-038-1 (SRK 2025b). These changes were summarized in the introduction of this document. SRK has also completed two technical evaluations of proposed water mitigations, including the reliability and risks associated with effective treatment, in addition to the expected beneficial change in 2024-2025. These are described in the following two reports:

1) Effect of Mitigation Controls on Water Quality and Quantity of the Tenas Project (Attachment OW-038-2, SRK 2025c), which is an updated version of the memo that described the effect of mitigations (from May 2022). The updated memo includes the changes made to the Water and Load Balance Model between 2022 and 2024 (as described in the updated Water and Load Balance Model report 2025 [Attachment OW-038-1]), and
2) Tenas Project – Best Achievable Technology Assessment Report (Attachment OW-038-3, SRK 2025d).

A regional groundwater model was developed for the Tenas Project's EAC Application to help quantify the potential reduction of flow in Tenas and Four creeks, including during low flow conditions. The groundwater model was developed in 2022 and was updated in 2024 (Attachment OW-038-4, SRK 2024b). That model estimated groundwater fluxes, discharge, and recharge from the Project. Groundwater connections are incorporated into the water and load balance model based on three components: direct connections to Project infrastructure, changes to stream baseflow, and load transport to streams. The change in water levels (groundwater head) within the Management Ponds, Control Ponds, and the open pit affect the groundwater discharge rates to each downstream creek and river. The calibrated rainfall-runoff model (in the water and load balance model) included a constant unit baseflow for each major creek, which is applied to each associated prediction node.

To understand the change to baseflows attributed to the mine development, the groundwater model predicted baseline baseflow and baseflow during mining at each prediction node for each scenario. The forecasted change to baseflow between baseline conditions and mining conditions were directly applied to the baseflow component for each prediction node in the water balance model. Baseflow dominates the total streamflow during winter months but represents a minor portion of the total streamflow during the open-water season, late summer flow included. Baseflow rates in the receiving environment increase or decrease, depending on location in relation to the open pit and the Management Ponds. While the water outflows from the mine site into the groundwater system and into the creeks happen instantaneously due to its relation to the water head, there is a natural lag between the timing of seepage at the source and the seepage containing contaminant particles being observed within the various stream prediction nodes (because of the slow travel time of groundwater). Particle tracing within the groundwater model (Attachment OW-038-4, SRK 2024b) revealed that a small portion of seepage reaches the adjacent reach of Tenas Creek before end of mining, but that most of the seepage will not be observed until well past closure. A conservative estimate is used in the water and load balance model of 25 year lag before the particles reach the streams. The contaminant load reaching each prediction node is calculated based on the percentage of particles leaving each Management Pond, open pit or Tenas Control Pond that reach each node under steady-state conditions, taking into account the dilution of mine seepage into the groundwater system.

The mitigations that affect stream flows in Four and Tenas Creek are represented by Mitigation Controls 2 and 3 in the "Effect of Mitigation Controls on Water Quality and Quantity of the Tenas Project" memo (Attachment OW-038-2, SRK 2025c), which include the thicker liners compared to those used in the Final EAC Project Case (2024). The different liners used in the 3 different scenarios is outlined as follows:

Final EAC Project Case (2024):

- Soil-bentonite liner (0.3m) for EMP, NMP, and WMP (excluding WMP End Wall rock);
- Bituminous geomembrane liner for the Tenas Control Pond.

Mitigation Control 2:

- Soil-bentonite liner (0.56m) for EMP, NMP, and WMP (excluding WMP End Wall rock);
- Bituminous geomembrane liner on top of soil-bentonite liner (0.15m) for the Tenas Control Pond.

Mitigation Control 3:

- Bituminous geomembrane liner on top of soil-bentonite liner (0.3m) for EMP;
- Soil-bentonite liner (0.56m) for NMP, and WMP (excluding WMP End Wall rock);
- Bituminous geomembrane liner on top of soil-bentonite liner (0.15m) for the Tenas Control Pond

The effects of thicker liners are two-fold: reducing groundwater seepage to the streams compared to Final EAC Project Case (2024) and reducing contaminant load transported into the groundwater system pathways due to reduced seepage. Figure 1-1 illustrate the effect on flow in Tenas Creek (WQS04) and in Four Creek (WQS03_DS) due to the effect of thicker liners. In both cases, thicker liners cause a greater percent reduction in creek flows. Figure 1-2 shows the expected reduction in selenium concentrations if thicker liners are used. The reduction in concentrations is expected to be more significant for Four Creek. Note that the effects on flow and on concentrations do not occur at the same time because of the groundwater travel time delay the arrival of management and control pond water by about 25 years.

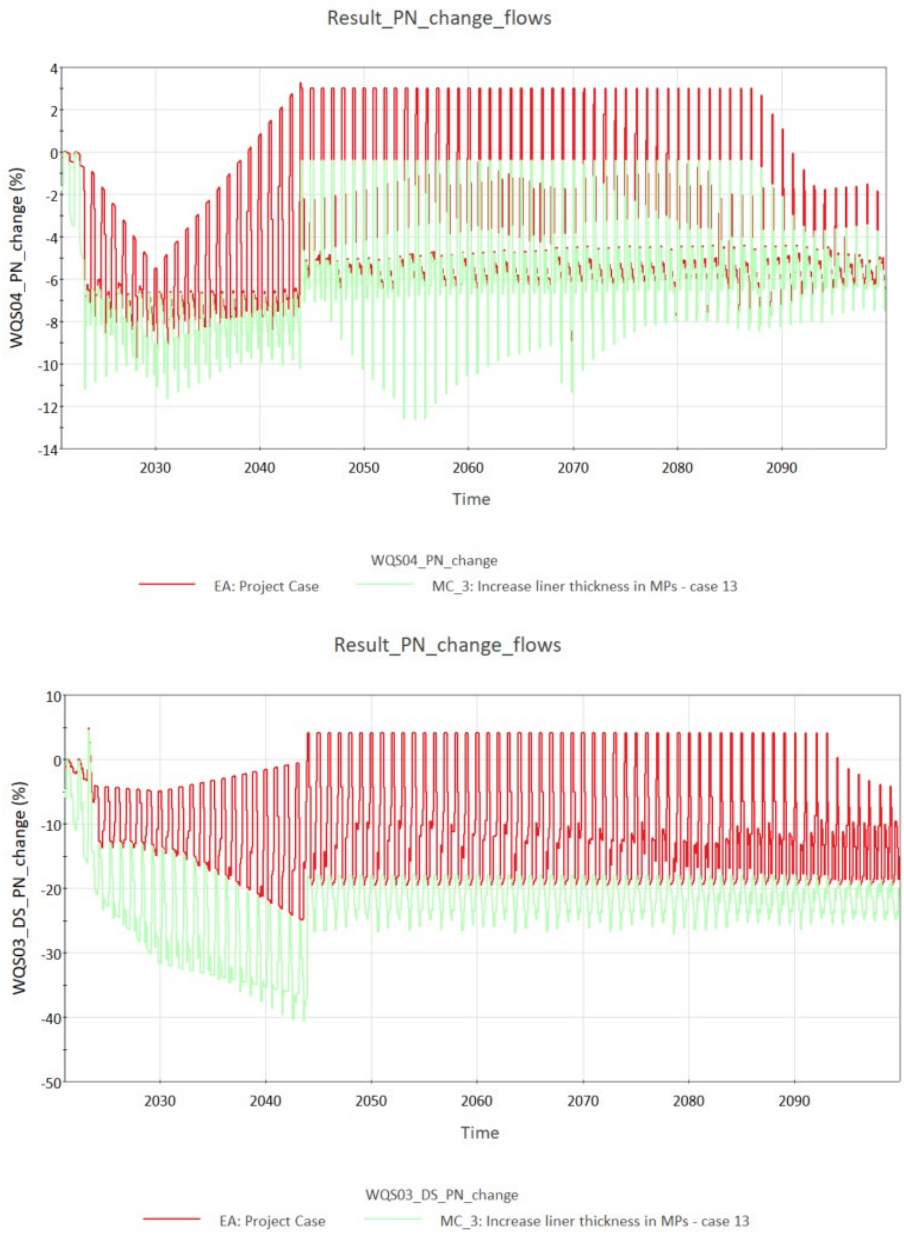

Figure 1-1: Percent change in flows between mining and pre-mining conditions at prediction node WQS04 (Tenas Creek) and WQS03_DS (Four Creek) for two scenarios: Final EAC Project Case (2024) in red and Mitigation control 3 in green (Thickest liners)

Figure 1-2: Modelled concentrations of total selenium at prediction node WQS04 (Tenas Creek) and WQS03_DS (Four Creek) for two scenarios: Final EAC Project Case (2024) in red and Mitigation control 3 in green (Thickest liners)

Additional Information about Proposed Mitigation Measures and Best Management Practices:

The risks and beneficial effects of water mitigation controls were evaluated using the water and load balance model for the Tenas Project (Attachment OW-038-1, SRK 2025b). Table 1-1 shows a summary of mitigation control measures that were considered as part of the water and load balance evaluation. The mitigation controls can be categorized either as source control measures/best management practices (BMPs) or as best achievable technologies (BATs). This distinction is relevant because BC ENV has issued guidance on how candidate BATs must be evaluated (BC ENV 2024). That guidance states that BMPs must be evaluated separately and prior to a BAT assessment. In other words, a mine operation should first implement BMPs, which include source control measures such as mine rock covers or inundation of mine rock as well as operational practices that are carried out on a day-to-day basis such as the use of blast-hole liners. Only after BMPs have been considered and included as part of the Project description can BATs be considered. BATs are technologies that require construction of site infrastructure and implementation of water treatment equipment – i.e., typically more conventional pump and tank-based water treatment options.

Table 1-1: Potential Additional Mitigation Controls

ID	Description	Candidate BAT or BMP
MC1	Improve the robustness of the water covers in the management ponds and reduce loadings from waste rock by increasing the site water inventory during freshet	**BMP**
MC2	Increase MP liner thickness and reduce seepage to streams (case 7)	**BAT**
MC3	Increase MP liner thickness and reduce seepage to streams (case 13)	**BAT**
MC4	Increase of process water intake to CPP plant	**BMP**
MC5	Addition of blasthole liners	**BMP**
MC6	Active/Passive flocculation in TCP	**BAT**
MC7	In-situ GBR Active in MPs	**BAT**
MC8	Active treatment post TCP	**BAT**

Source: Attachment OW-038-3, SRK 2025d

Best Management Practices as Mitigation Control Measures (see also Attachment OW-038-2)

Through the development and design of the Tenas Project, TML has made efforts to include as many source control measures and BMPs into the Base Case as are practically achievable to manage water quality within and downstream of the Project Area, including:

- Inundation of potentially acid generating (PAG) rock in the management ponds on site to prevent potential Acid Rock Drainage,

- Lining of the management and control ponds to reduce seepage and groundwater recharge,
- Progressive reclamation and covering of non-potential acid generating rock (non-PAG) backfilled into the open pit,
- Construction of dam/buttresses and backfills (and any potential external permanent piles and stockpiles) using a bottom-up construction methodology,
- Attenuation of treated effluent in Tenas Control Pond,
- Pacing of treated surface water discharge to the open water season,
- Erosion prevention in collection and diversion channels,
- Sediment control in sedimentation/control ponds, and
- Clean (non-contact) water diversions to route water around Project activities.

In addition to these, three other BMPs that had not previously been considered were evaluated in the water and load balance model study, namely (see Table 1-1):

- MC1: Improve the robustness of the water covers in the management ponds and reduce loadings from waste rock by increasing the site water inventory during freshet,
- MC4: Increase of process water intake to CPP plant, and
- MC5: Addition of blasthole liners.

Of these three, the addition of blasthole liners (MC5) was found to be suitable and feasible as a water quality mitigation measure for the Tenas Project, and TML therefore committed to using liners for the future mine operation. The two other BMPs, improving the robustness of the water cover (MC1) and increasing process water intake to CPP plant (MC4) were not considered to be suitable because they would (or could) reduce streamflow in Four Creek in the open-water season months (MC1) or would not lead to any notable improvement in the quality or quantity of discharge from the site (MC4).

Blasthole liners work by reducing the amount of blasting residuals (undetonated ammonium nitrate fuel oil (ANFO) explosives) that dissolved into the mine contact water and thereby increases ammonia and nitrate concentrations. Undetonated ANFO is one of the main sources of nitrogen (nitrate, nitrite, and ammonium) in contact water at the mine site. Loadings of residual nitrogen species that leach from the rock into the mine water can be reduced if blasthole liners (long plastic bags that fit into the blasthole) are inserted as holes are loaded with explosives. The primary purpose of the liners is to prevent water from contacting and dissolving the ANFO explosive prior to blasting. For this mitigation control, the model assumes a total ANFO loss (and dissolution in mine water) of 1.25% when blasthole liners are used compared to 2% loss when liners are not used, which corresponds to a 32% reduction in ammonia, nitrate, and nitrite loadings.

The use of blasthole liners increases the cost of mining because of the time it takes to insert liners into the blasthole before loading the explosives as well as the cost of the liners. However, there are no notable operational risks associated with the use of liners, only benefits.

Best Achievable Technologies as Mitigation Control Measures (also see Attachment OW-038-2)

As discussed above, a BAT assessment was completed for the Project after review and selection of BMPs. The BAT assessment methodology followed guidance issued by the BC Ministry of Environment and Climate Change Strategy (BC ENV) in November 2024. The purpose of the BAT assessment was to identify technologies that are best suited for managing or mitigating identified Parameters of Concern (POCs) in modelled groundwater seepages and surface water discharge of treated effluent from the Project. POCs included nitrate, nitrite, sulphate, aluminum, cadmium, cobalt, copper, iron, nickel, zinc, molybdenum, and selenium.

The BAT assessment is required to consider all possible technologies that potentially could remove one or more POCs. The BAT assessment for the Tenas Project identified 24 different technologies that potentially could be implemented. BC ENV recognizes that even though a technology theoretically could remove one or more POCs, there may be other reasons why it would not be suitable for treating water at a mine site. The BAT methodology lists the following reasons why a technology can be considered unfeasible:

- Inability to achieve environmental criteria:
  - For example, a technology may remove some nitrate or metals but not enough to meet anticipated water quality effluent limits or downstream objectives.
- Lack of existing commercial applications:
  - Technologies considered as BATs must, at a minimum, have a demonstration system operating at near full-scale in the same industry and under similar site-specific conditions. BC ENV's guidance states that technologies considered for an Environmental Assessment Certificate application must have a Technology Readiness Level of 7, 8, or 9 to be considered potentially feasible.
- Operational complexity:
  - This criterion considers several factors which may include, but are not limited to operator attendance requirement, chemical requirements, ease of process control, level of automation, level of expertise required to operate the system, maintenance requirements, and downtime expectations (for maintenance and repairs).

After evaluating the feasibility of the 24 identified technologies, nine were found to be potentially feasible and carried on to a more detailed assessment:

1. Passive/Active Flocculation.
2. In-situ Active Gravel Bed Reactor (GBR).
3. Membrane Filtration + Moving Bed Bioreactor (MBBR).
4. Membrane Filtration + MBBR + High Density Sludge Lime.
5. Membrane Filtration + MBBR + Sulphide.
6. Membrane Filtration + MBBR + Ferric.

7. Membrane Filtration + MBBR + Ion Exchange.
8. Zero Liquid Discharge.
9. Modified Liners in Management and Control Pond.

In addition to these nine, the Base Case with only BMPs included (i.e., the case with no additional BATs implemented) were also considered for comparison.

BC ENV's guidance requires that the following general categories are used to evaluate BATs:

- Reliability.
- Control-effectiveness.
- Environmental impacts, and
- Cost effectiveness.

Table 1-2 shows the criteria included in each of the categories, and how much importance (or weight) is assigned to each in the final assessment. TML added the evaluation category "Adherence to Yintah Management Directives" to formally include at least some direct consideration of first nations interests.

The evaluation categories in Table 1-2 include reliability, risk, and expected benefits, which were referenced in the review comment. Risk and robustness are included in the reliability category. BC ENV described the 'risk assessment' criterion as follows:

"Risk Assessment - Conduct a risk assessment for each technology to identify the potential risks associated with the implementation, operation, and maintenance of the technology. These risks may include but are not limited to the likelihood of process failure, environmental and human health risks resulting from process failure, as well as risks associated with secondary waste production (by-products) that may impact the environment and human health."

Table 1-2: BAT Assessment Criteria and Weight Distribution

Assessment Criterion	BC ENV's Suggested Weights	TML's Proposed Weights
Reliability	**20**	**20**
Risk Assessment	5	5
Robustness	5	5
Scalability	5	5
Long-term Viability	5	5
Control-Effectiveness	**35**	**30**
Pollutant Reduction	20	20
Toxicity Reduction	15	10
Environmental Impacts	**20**	**25**
Energy Efficiency	5	5
Greenhouse Gas Emission	6	6
Footprint	4	4

Secondary Waste Production	5	5
Adherence to Yintah Management Directives	-	**5**
Cost-Effectiveness	**25**	**25**
Efficient Use of Existing Resources	3	3
Life Cycle Cost Analysis	22	22
Total	**100**	**100**

Source: Attachment OW-038-3

BC ENV describes the 'robustness' criterion as follows:

"Robustness - means consistent and reliable performance under various conditions over the technology operational life. Evaluate technologies based on their ability to maintain effectiveness and performance under the fluctuations in operating conditions such as effluent quality (physical and chemical characteristics) and quantity (flow)."

The expected beneficial water quality changes associated with water treatment technologies were evaluated as part of the control-effectiveness category. Additional information on other assessment criteria listed in Table 1-2 that were not specifically referenced in the review comment are included in the BAT assessment report in Attachment OW-038-3.

From a water treatment and water quality protection perspective, the risk profile for the project is low. The updated water quality model results indicates that all water quality parameters in receiving waters downstream of the Project are expected to remain below chronic BC water quality guidelines (except for copper, which is naturally elevated in background waters). Therefore, if water treatment were to be implemented and subsequently fail it is unlikely that the lack of water treatment would adversely affect water quality in downstream waters since concentrations are expected to remain below BC water quality guidelines even without any water treatment.

As discussed above, the BAT assessment weighted the potential beneficial effects of implementing various treatment options versus the risk, costs, and general consequences associated with each option. The multiple-accounts analysis (MAA) evaluation (Table 1-3) shows the scores assigned to the expected beneficial changes (pollutant reduction, toxicity reduction, and robustness categories) as well as scores assigned for reliability and risks (robustness and risk assessment categories). The categories are scored on a scale from 1 to 5, where 1 represents a poor score (poor expected performance, low reliability, or high risk) and 5 represents a good score (expected to perform well, highly reliable, or low risk).

Most of the technologies considered achieved scores of 3 or 4 (out of 5) for the risk assessment and robustness (i.e., reliability) categories. This means that reliability and risks associated with the different options are somewhat similar. The pollutant reduction category, on the other hand, shows that there is a greater different in expected beneficial effects with scores ranging from 1 to 4.5.

Table 1-3: MAA Assessment of Candidate BAT Scenarios

		Base Case with BMPs	Passive/Active Flocculation	In-situ Active (GBR)	RO + MBBR	RO + MBBR + HDS Lime	RO + MBBR + Sulphide	RO + MBBR + Ferric	RO + MBBR + Ion Exchange	Zero Liquid Discaherge	Modified Liners in Water Management Ponds

Source: Attachment OW-038-3

However, the better performance comes at a cost with lower scores for cost-effectiveness and environmental and socio-cultural impacts.

The following was concluded based on the assessment of Best Achievable Technologies for the Tenas Project:

- The Base Case option is a highly rated and feasible option for protecting downstream water quality without the need for any further BMPs or technologies to be incorporated.
- In-situ Active GBRs with the Base Case and Passive/Active flocculation with the Base Case are also highly rated and feasible options that should be retained as contingency options during permitting if water quality predictions for the Project differ substantially from actual conditions observed during the development of the Project and water quality monitoring results are trending toward exceedances of the WQGs.
- To improve on the technology readiness level of the In-situ Active GBR technology, TML should develop a Pilot In-situ Active GBR within the Coal Processing Plant (CPP) Sedimentation Pond or alternate.
- Active tank-based water treatment options with the Base Case are less suitable but feasible and should be retained as contingency options during permitting if water quality predictions for the Project differ substantially from actual conditions observed during the development of the Project and water quality monitoring results are trending towards exceedances of the WQGs.
- Modification of management and control pond liners with the Base Case is less suitable but feasible and should be retained as a contingency option for the WMP during permitting if water quality predictions for the Project differ substantially from actual conditions observed during the development of the Project and water quality monitoring results are trending towards exceedances of the WQGs.

Additional details concerning the two studies cited in the above response are available in Attachments OW-038-2 and OW-038-3.

Finally, to address the last point of this IR, TML has carefully considered the reduction in flows and is not considering any mitigation that would induce further reduction in flows beyond what is shown in the Final EAC Project Case (2024). In addition, no exceedances above BC WQG have been shown to occur, outside of already elevated background concentrations such as copper. The current model results (in the Final EAC Project Case [2024]) showing reduction in flows from baseline is currently assessed by SLR Consulting for its effects on fisheries.

As requested by OW, TML will discuss appropriate incorporation of the results of forthcoming information related to water quality into Project design, monitoring, mitigation, and adaptive management plans.

1.3 IR# OW-039 (New IR)

1.3.1 Information Request

The reliability and risks of each option are not discussed, and very little information is provided on situations where the mitigation option may be less effective/ ineffective (i.e., high or low run off conditions, liner failure, etc.). The water treatment plan option (Control 5) appears to be one of the most effective options, particularly when combined with other options. However, the design details of the water treatment plant have not been developed (which the proponent acknowledged in the document), and the reductions in constituent concentrations are only assumed. This would require additional storage and appropriate treatment rates, along with additional energy and waste disposal costs. As water treatment, in combination with other approaches, is the most effective way of reducing exceedances from the ponds, this option should be pursued but TML must provide more information on the details of that process (including detailed operations of the treatment facility over time, energy and water use, and efficiency of treatments, etc.). TML must provide further information on alternative treatment plans and outcomes that describe how the water treatment facility would be designed, what standards would be used, the operation, and the duration.

1.3.2 Response

TML acknowledges the comment. Please see complete response and figures/tables to this comment in the SRK memo [Tenas Project Information Request Responses from Office of the Wet'suwet'en memo, SRK June 2025] Attachment OW-011-1.

The majority of the information requested by Office of the Wet'suwet'en is included in the 2025 Best Achievable Technology (BAT) assessment report prepared by SRK consulting for TML (SRK 2025d and Attachment OW-038-3). The BAT assessment was conducted in parallel with a water quality model study that also looked at implementation of mitigations controls (i.e., Best Management Practices, or BMPs in the mitigation report (SRK2025b or Attachment OW-038-2)). In the BAT assessment, all possible water treatment alternatives are evaluated at a conceptual level and are scored and ranked according to various performance, reliability, environmental impact (including energy consumption), and cost criteria in accordance with 2024 guidance issued by the BC Ministry of Environment and Parks.

The BAT assessment specifically evaluates suitability and risks associated with water treatment technologies. For example, the assessment concluded that in-situ gravel bed reactors (GBRs), active and passive flocculation, and active water treatment options should be incorporated into the development plan as contingency measures for the Tenas Project in case parameter concentrations in future discharges are higher than modelled by the water and load balance model.

As discussed in the response to OW-038, the risk associated with treatment processes that may be less effective than presumed is low because BC water quality guidelines prescribed for downstream receiving waters are expected to be met even if no water treatment is implemented. As also discussed in response to OW-038, the active water treatment plant options score better (scores of 2.5 to 4.5) than best management practices alone (score of 1) for treatment performance. However, the active water

treatment plant options have considerable drawbacks that do not make up for their better treatment performance, and active water treatment plants are therefore not the preferred option to go forward with for this Project when evaluating holistically all aspects that need to be considered when ranking a particular technology.

Nonetheless, TML has committed to including active water treatment options as contingencies in case the best management practices do not perform as well as expected or in case the mine water quality has higher parameter concentrations than modelled. Active water treatment, active/passive flocculation and/or In-situ Active GBRs will be implemented via a trigger action response plan that will include the monitoring of parameters of concern in the management and control ponds, at the end of the pipe, in the receiving environment, and groundwater seepages. If monitoring data indicates that one of these contingencies will be needed to avoid significant adverse effects to the surface/groundwater Valued Components it will be implemented at that point.

Detailed design information requested in this review comment associated with active water treatment will be provided as part of permitting process for the two contingency options recommended by the BAT as it is outside the requirements of a BC environmental assessment. As recommended by the BAT report in Attachment OW-038-2) an active water treatment plant is not the highest ranked option to pursue and is being maintained as contingency option that will be implemented as required based on a Trigger Action Response Plan (TARP), which will be developed for permitting. The highest ranked options are to (1) continue with the existing Base Case (also called Final EAC Project Case 2024) with best management practices incorporated (2) use passive or active flocculation to remove suspended solids, (3) implement In-situ Active GBRs in the management ponds in addition to the BMPs incorporated in the Base Case. TML has committed to developing a pilot In-situ Active GBR in the Coal Processing Plant Sedimentation Pond or alternative pond to improve this technology's TRL to at least an 8 for the targeted Parameters of Concern prior to the end of Year 4 of the Operation Phase.

The reduction in POC concentrations that can be achieved by different treatment technologies are generally very well understood. Most technologies are operating at many different mine and/or industrial sites all over the world. True site-specific performance testing can only be performed once the mine water from the Tenas Project becomes available. Until that happens, the technology performance estimates will be based on reliable data from other sites.

As discussed in the response to OW-038, TML considered 24 alternative treatment options in the BAT assessment (Attachment OW-038-3). The preferred options were to proceed with (1) the Base Case that includes best management practices, (2) use passive or active flocculation to remove suspended solids, (3) active In-situ GBRs, and finally (4) active water treatment, most likely using reverse osmosis and moving bed bioreactors with high density sludge lime treatment.

The design of each of these control measures would begin with the development of a detailed design basis, which would specify the flow rates, water quality, and temperature of the water to be treated, how much water would need to be treated in each month, and what effluent concentrations would have to be achieved. Based on this design basis, engineers will proceed with preliminary designs, which will be reviewed at 30%, 60%, and 90% complete stages. Following these reviews, issued for tender designs will be submitted to water treatment equipment companies who will issue proposals for

manufacture, supply, and construction of the water treatment facilities. At that stage, a final design for construction is completed. Design standards to be used can be specified in the design basis, or they can be defined by each equipment supplier as part of the proposal.

The company supplying the active water treatment equipment would be responsible for commissioning the active water treatment system, but TML would be responsible for operating it for the life of the mine and potentially beyond into the Post-Closure phase. According to the updated water quality model results, active water treatment is not expected to be necessary during the operating phase of the mine or following closure as model results show no water quality guideline exceedances in the Receiving Environment under the Base Case (Final EAC Project Case 2024, as presented in Attachment OW-038-1). Active water treatment should therefore not be necessary. However, TML will develop a TARP that specifies criteria for when and under what circumstances active water treatment would be implemented despite the expectation that no treatment is needed based on the modelling work completed.

As requested by OW, TML will discuss appropriate incorporation of the results of forthcoming information related to water quality into Project design, monitoring, mitigation, and adaptive management plans.

1.4 IR# OW-040 (IR 356-1 and IR 356-2)

1.4.1 Information Request

We are unable to find the documents containing the results of this IR response, "Final EA Water and Load Balance results", or Attachment IR 356-1 as the IR response does not provide further information regarding where these documents are located. We are unable to find any documents with that name in the review materials provided to us and therefore could not review the IR. Please provide these documents, including figures for each of the requested scenarios in the IR (Tributary receiving discharge above confluence with Goathorn Creek, and Goathorn Creek below confluence with tributary receiving discharge); projected water quality from baseline through to post-closure; and updated figures from the WLBM report (Fig 2.2-2.4 of App 4.3) that showed incorrect connections of the three creeks (Four Creek, Tenas Creek, Goathorn Creek).

1.4.2 Response

TML acknowledges the comment. Please see complete response and figures/tables to this comment in the SRK memo [Tenas Project Information Request Responses from Office of the Wet'suwet'en memo, SRK June 2025] Attachment OW-011-1.

Please refer to Attachment OW-038-1 for the Updated Water and Load Balance Model report (SRK, 2025) and refer to Attachment OW-040-1 for Updated Figures 2-2 through 2-4 with corrected connections for Four, Tenas, and Goathorn Creeks.

As requested by OW, TML will discuss appropriate incorporation of the results of forthcoming information related to water quality into Project design, monitoring, mitigation, and adaptive management plans.

1.5 IR# OW-041 (IR 356-1 and IR 356-2)

1.5.1 Information Request

We are unable to find the documents containing the results of this IR response, "Final EA Water and Load Balance results", or Attachment IR 356-1 as the IR response does not provide further information regarding where these documents are located. We are unable to find any documents with that name in the review materials provided to us and therefore could not review the IR. Please provide these documents, including figures for each of the requested scenarios in the IR (Tributary receiving discharge above confluence with Goathorn Creek, and Goathorn Creek below confluence with tributary receiving discharge); projected water quality from baseline through to post-closure; and updated figures from the WLBM report (Fig 2.2-2.4 of App 4.3) that showed incorrect connections of the three creeks (Four Creek, Tenas Creek, Goathorn Creek).

1.5.2 Response

TML acknowledges the comment. Please see complete response and figures/tables to this comment in the SRK memo [Tenas Project Information Request Responses from Office of the Wet'suwet'en memo, SRK June 2025] Attachment OW-011-1.

Please refer to Attachment OW-038-1 for the Updated Water and Load Balance Model report (SRK, 2025c) and refer to Attachment OW-041-1 for Updated Figure showing the new Prediction Node WQSEA1, which is below the confluence with tributary receiving the Project discharge.

As requested by OW, TML will discuss appropriate incorporation of the results of forthcoming information related to water quality into Project design, monitoring, mitigation, and adaptive management plans.

1.6 IR# OW-042 (New IR)

1.6.1 Information Request

Reporting the use of different time scales is troublesome, especially in a region with high seasonal variability. The caching of all "open water" months into one "summer season" is not appropriate as there are very different climate and ecosystem processes influencing or influenced by spring vs summer vs fall water quality dynamics. The use of one seasonal value may be skewed by over-represented high or low values that occur during more months, and therefore not representative of periods exhibiting seasonally low or high values. Monthly values would be more appropriate to capture full seasonal variability. Please provide this information. In addition, we were unable to fully review this

IR because we could not locate the referenced document "Final EA Water and Load Balance Report". Please provide this information.

1.6.2 Response

TML acknowledges the comment. Please see complete response and figures/tables to this comment in the SRK memo [Tenas Project Information Request Responses from Office of the Wet'suwet'en memo, SRK June 2025] Attachment OW-011-1.

TML agrees with the reviewers that seasonal background baseline parameter concentrations may be skewed by specific months within the baseline dataset that is available. However, some months contain only a few datapoints (3), which is the minimum statistical sample size from which to calculate representative percentiles for each month, for each parameter and within each creek. However, to investigate an answer this IR and as the minimum sample size of 3 was achieved for all months, monthly seasonal background baseline concentrations were modelled for each parameter used in the model (see Attachment OW-42-1) and compared to the seasonal background baseline concentrations used in the Final EAC Project Case (2024). Model results from the two scenarios were also compared to the BC water quality guidelines applicable for each stream.

As suggested by the information request, the use of background monthly averages rather than background seasonal averages increases the modelled variability in the modelled results for the receiving environment. Table 1-4 shows maximum monthly modelled results that exceeds the water quality guideline calculated for the respective creeks for both model cases (seasonal background concentrations [Final EAC Project Case 2024] and monthly background concentrations). In both cases, dissolved cobalt exceeds in Four Creek as the main load of cobalt to the creek is coming from the Project. Similarly for both cases, dissolved copper was modelled to exceed water quality guideline in Tenas and Goathorn Creek. Total aluminum only exceeds the water quality guidelines under the monthly background concentration case in Four, Tenas and Goathorn Creeks. Similarly, total iron and total beryllium also exceed water quality guideline in Tenas and Four Creeks, respectively.

Both dissolved copper and total aluminum are naturally elevated in the background baseline dataset and are often found in exceedance of the BC Water Quality Guidelines, as highlighted by the baseline study. The water quality model results that use monthly or seasonal background concentrations indicates that the load coming from Project represents often a few percents only (<5%) of the total load for the parameters that exceed water quality guidelines in the creeks and rivers. Therefore, the effluent from site is not expected to cause any measurable increase in the naturally elevated background concentrations.

Note that total Beryllium was further examined, and it was determined that the indicated exceedances are due to higher detection limits (0.0001 mg/L to 0.0015mg/L) that are close to or above the water quality guideline for total beryllium (0.00013mg/L). These elevated detection limits are biasing the results and showing artificial exceedances. In fact, beryllium concentrations was never measured above detection limit in the baseline dataset and no beryllium load comes from site.

The parameters listed in Table 1-4 have already been identified as Parameters of Concerns in the BAT assessment (except for total beryllium, which is always below the analytical detection limit). Therefore, options for removing these constituents from site water before it is discharged have already been evaluated and TML has committed to implementing the recommendations made in the BAT assessment. TML has also committed to continue developing the water quality baseline dataset to improve the characterization of monthly/seasonal conditions such that a greater range of background conditions could be incorporated in the next revision of the WLBM during permitting.

The monitoring program proposed will have reference sites above where the Project is expected to have any effects and naturally occurring monthly exceedances at these locations will be able to be understood in the context of measured values downstream where the Projects is expected to have an influence on parameter concentrations.

As requested by OW, TML will discuss appropriate incorporation of the results of forthcoming information related to water quality into Project design, monitoring, mitigation, and adaptive management plans.

Table 1-4: Scenario exceedances when applying monthly background source terms instead of seasonal for the Final EAC Project Case (2024)

Creek	WQG (mg/L)	Maximum monthly concentration exceeding (mg/L) in FEAC 2024 *with seasonal background ST*	Maximum monthly concentration exceeding (mg/L) in FEAC 2024 *with monthly background ST*	Background concentration (season or monthly average) for period of maximum monthly WQG exceedance	
				Seasonal (mg/L)	*Monthly (mg/L)*

1.7 IR# OW-043 (New IR)

1.7.1 Information Request

The organization of various ponds and their connectivity, as well as the lack of data associated with each pond is an obvious source of confusion in the application. This theme arises in many comments throughout the proponent's IR response. Discharges from sedimentation ponds (excluding Tenas Control Pond/North Management Pond and Rail Infrastructure Pond) are directed towards natural

ground. The Proponent plans to convey this water along natural flow pathways to eventually reach downstream watercourses. Despite use of pumps and other structures for controlled release, there is risk of overflow and higher amounts of release during high rain events, which may increase downstream erosion potential. The Proponent must provide a clear map of the location and connectivity of each pond along with an associated table that includes all the requested information from the IR.

1.7.2 Response

TML acknowledges the comment. Please see complete response and figures/tables to this comment in the SRK memo [Tenas Project Information Request Responses from Office of the Wet'suwet'en memo, SRK June 2025] Attachment OW-011-1.

Attachment OW-043-1 provides the map requested and demonstrates that the ponds are not readily connected to one another nor the Tenas Control Pond/North Management Pond. Attachment OW-043-2 provides the modelled water discharges, water quality predictions, operational period, mitigations and residual effects associated with erosion and sediment control for the ponds. TSS is not modelled from any pond but rather is a source control design requirement of each pond (ponds have been designed large enough for expected material) so that no pond will release higher than an average of 35 mg/L during a 1 in 10 year storm event at the end of pipe and survive a 1 in 200 year event as required by the regulations By the time this water reaches an actual water course via overland route through vegetation the TSS levels will be much lower than end of pipe levels thanks to natural attenuation by vegetation along the discharge route.

The sedimentation ponds are 100% controlled by pumping to a velocity reducing non-erosional structure like a concrete box which will slow water flows to a level that can then flow into the armored emergency spillway which reduces flows even further through the spillway itself. Water then flows to an apron discharge structure that finally discharges to the surrounding environment to ensure water velocities do not cause erosion in the receiving environment.

As a contingency to potential erosion and sediment control, a risk assessment will be performed with the OW for the likely discharge path for overland flow and if additional erosion sediment control measures are identified to be added such as silt fencing, ability to place floc blocks in storm events will be incorporated. This can be done immediately. If during this review, the engineered discharge system and/or sedimentation ponds also require modification to further reduce potential erosion and sediment control these can be completed. Another contingency will be the ability to install pump back systems in these sedimentation ponds to divert flows to the Tenas Control Pond if necessary, where TSS levels are expected to be addressed by the large settling time available in this ponds plus contingent flocculation/coagulation facilities which again can be done immediately. A final contingency would be secure an active mechanical system that can treat higher TSS inflow water to meet regulatory guidelines which again be done quickly as these systems are readily available within the province

TML will provide an updated discharge management plan during the permitting process for OW and regulatory agencies to review and provide feedback on.

During the permitting process, TML will provide detailed plans for the required EMA authorization applications including discharge management plans for the OW and regulatory agencies to review and provide input.

As requested by OW, TML will discuss appropriate incorporation of the results of forthcoming information related to additional sedimentation ponds to Indigenous interests or Indigenous nations into Project design, monitoring, mitigation, and adaptive management plans.

1.8 IR# OW-044 (New IR)

1.8.1 Information Request

Note that an IDZ will not be considered during permitting without an adequate BAT assessment. Given that a new BAT assessment has been performed with alternative treatment options, the IDZ study would need to be redone to account for water quality differences derived from various different treatment options. The comment does not address the need to also evaluate cumulative effects around the IDZ. In addition, the proposed frequency of monitoring for exceedances is inadequate given the risk to downstream fish. These ponds will be monitored monthly to evaluate toxicity results against authorized limits for lethality of Rainbow Trout. If exceedances exist, a number of actions are proposed to reduce exceedance, but given the frequency of monitoring (monthly) and the amount of time required for implementation of the proposed actions, it is possible exceedances (and downstream negative effects) could persist for a substantial amount of time (months) before any resolution. This presents a considerable prolonged threat to fish and ecosystem health. TML must correct these discrepancies.

1.8.2 Response

TML acknowledges the comment.

Please refer to Attachment OW-044-1 for the Updated 2025 IDZ report (SRK 2025e). The report updates the IDZ assessment based on latest findings of Best Achievable Technology (BAT) assessment and updated effluent discharge information from the Water and Load Balance (WLB) model for the Project (Attachments OW-038-1 and OW-038-3). The assessment was carried out following the Technical Guidance 11 (TG11) produced by the BC Ministry of Environment and Parks. The IDZ is in Goathorn Creek below the confluence with a tributary that receives Project discharge from the Tenas Control Pond (TCP) and North Management Pond (NMP) during operation and post closure, respectively. This also includes discharge from the sewage treatment plant during operation.

Three cases were defined based on conservative assumptions considering the in-stream flow and water quality of Goathorn Creek, and discharge rate and quality of Project effluent, using a combination of monthly maximum or average water quality concentrations with typical source terms along with mean flow or 7Q10 low-flows during effluent release period (OW-044-01), according to the following Table 1-5:

Table 1-5: Definition of IDZ assessment cases

Cases	Goathorn Creek		Project Effluent	
	Flow condition	**Water quality**	**Effluent discharge**	**Effluent quality**
Worst case	7Q10 low-flow (1) of the lowest dilution month	75th percentile background concentration	Maximum discharge for lowest dilution month	Maximum concentration with typical source terms
Reasonable worst case	Lowest 7Q10 flow during open water months	50th percentile background concentration	Maximum discharge for the same lowest 7Q10 month (open water)	Maximum concentration with typical source terms
Expected case	Mean flow during effluent release period (2)	50th percentile background concentration	Average discharge during effluent release period	Average concentration with typical source terms

Source: Attachment OW-044-1 (SRK 2025e)

Parameters identified as POCs in the BAT assessment and considered in this study are listed below:

- Nitrogen Nutrients: Nitrate, Nitrite
- Sulphate
- Metals: Aluminum (total), Cobalt (dissolved), Copper (dissolved), Iron (total), Nickel (dissolved), Zinc (dissolved)
- Oxyanions: Molybdenum (total), Selenium (total).

The modeled water quality of each POC in the Goathorn Creek was compared with the IDZ evaluation criteria for flow occupied within the IDZ and its length and width, based on TG11 guidance. For the worst case, nitrite and selenium do not meet WQG after complete mixing and aluminum exceeds the IDZ criterion for 100 m length during operation, while aluminum and selenium do not meet WQG after complete mixing in post-closure. This case is very conservative and unlikely to occur during very dry periods. Emphasis was placed upon the reasonable worst case and the expected case, which are conservative but provides realistic evaluation scenario. The results are summarized below.

During Operation:

- IDZ criteria to meet applicable WQGs are satisfied for nitrate, nitrite, sulphate, aluminum, cobalt, iron, nickel, zinc and molybdenum for the reasonable worst and expected cases.
- The IDZ extent of selenium exceeds the TG11 guidance (100 m length) for the reasonable worst case (153 m length), but meets the guidance for the expected case. WQG is exceeded for dissolved copper due to background concentration higher than the WQG, but the effluent concentration reaches background concentration after complete mixing.

During-Post Closure:

- POCs including nitrate, nitrite, cobalt, molybdenum, nickel and zinc do not register an IDZ, as the effluent concentrations are below the corresponding WQGs for the IDZ cases.
- IDZ criteria based on TG11 guidance is met for sulfate, aluminum, iron and selenium for the reasonable worst and expected cases. The guidance is exceeded for dissolved copper with background concentration higher than the WQG, but remains close to the background level after complete mixing.

The analyses of this study provided a range for spatial extent of IDZ for conditions anticipated for worst to expected cases as outlined in TG11. Based on the reasonable worst case and the expected case, a minimum IDZ length of 153 m and 44 m would be needed during operation and post-closure, respectively, to meet the instream WQGs of the POCs.

While there are other potential treatment options provided in the BAT (Attachment OW-038-3) these are only contingencies. The Final EAC Project Case (2024) does not have any parameter exceedances beyond the edge of the dilution zone besides baseline parameters that are already in exceedance. If in the future monitoring and the trigger action response plans indicate that a water treatment contingency needs to be implemented, a revised IDZ will be submitted as part of the notification for construction.

As illustrated by Attachment OW-043-1, the sedimentation ponds are not part of the WLBM and do not contribute to cumulative effects within the IDZ in Goathorn as their flows are either not directed towards Goathorn Creek's IDZ area or the pond is not operational when discharge is occurring from the Tenas Control Pond or from the North Management Pond. Furthermore, the sedimentation pond flows not included in the Project's WLBM are orders of magnitude lower than what is expected from the Tenas Control/North Management Pond. Finally, the ponds have been designed to not exceed a maximum average TSS concentration of 35 mg/L at the end of pipe.

Final Permit documents from the government will provide the required frequency of monitoring and what parameters need to be measured when the ponds are both flowing or not flowing.

As a contingency to potential erosion and sediment control a risk assessment will be performed with the OW for the likely discharge path for overland flow and if additional erosion a sediment control measures are identified to be added such as silt fencing, ability to place floc blocks in storm events these will be incorporated which can be done immediately. If during this review, it is identified that the engineered discharge system and/or sedimentation ponds also require modification to further reduce potential erosion and sediment control these, these modifications can be completed. Another contingency will be the ability to install pump back systems in these sedimentation ponds to divert flows to the Tenas Control Pond if necessary where TSS levels are expected to be addressed by the large settling time available in this ponds. Additional contingent flocculation/coagulation facilities will also have the ability to be done immediately. A final contingency would be secure an active mechanical system that can treat higher TSS inflow water to meet regulatory guidelines.

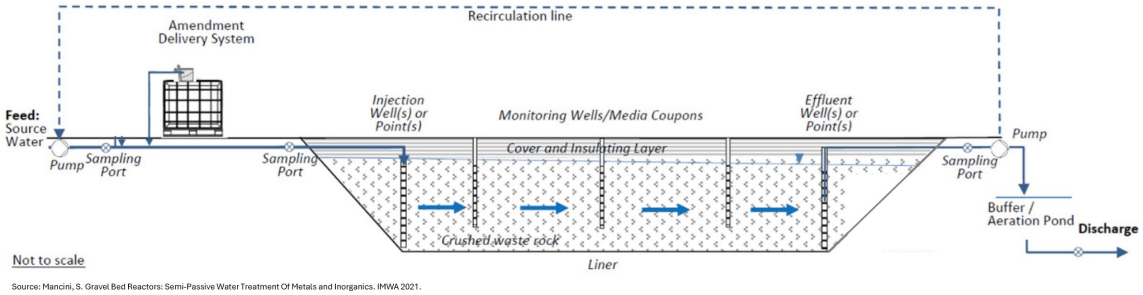
TML will provide an updated discharge management plan during the permitting process for OW and regulatory agencies to review and provide feedback on.

1.9 IR# OW-046 (IR# 176 – 20241115 TML Water Quality IR)

1.9.1 Information Request

Mitigation control scenarios are discussed and compared, including the pros and cons of expected changes in water quality. The most effective treatments for reduction of selenium and nitrate-nitrite in both control ponds are combinations of multiple mitigation strategies, many of which include the strategy of water quality treatment (listed as "mitigation control 5"). There are no plans or outcomes developed that describe how the water treatment facility would be designed or operate, some of the benefits are based on assumed targets met through treatment.

However, there are no actual plans or outcomes developed that describe how the water treatment facility would be designed or operate, some of the benefits are based on assumed targets met through treatment. This is acceptable but should be fleshed out further, and it should be confirmed that these targets can actually be met if this is considered a feasible option. The Proponent is also assuming the water quality treatment would persist past the end of closure as the model shows results out to 2100.



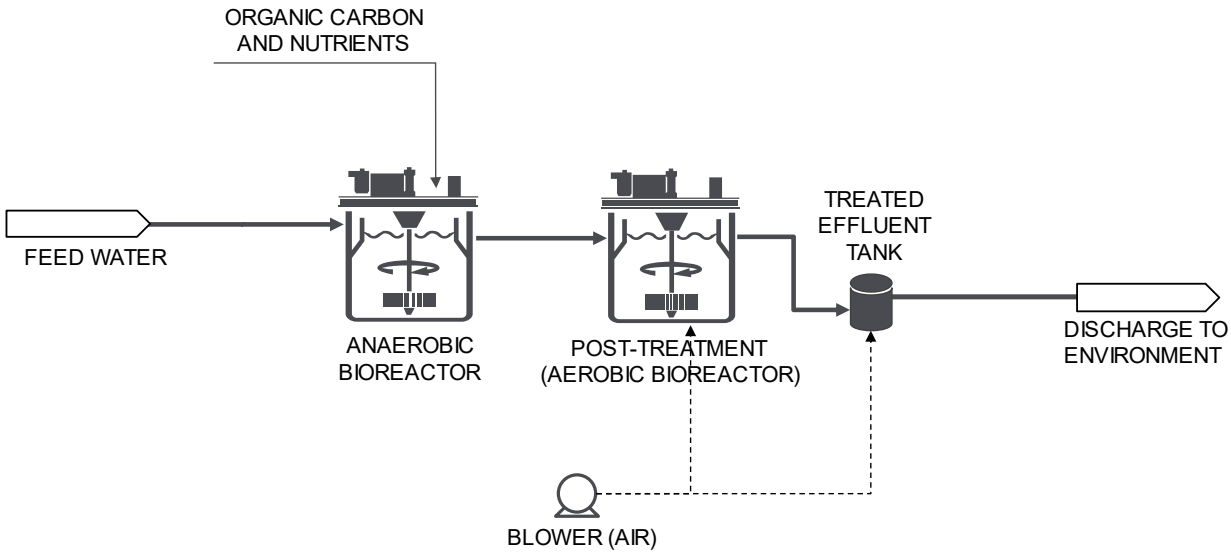
Additional information on water treatment facility is needed (design, standards, operation and duration) and should not be assumed if this is considered as an option, in conjunction with other mitigation strategies (it is included on the list of combined best options). There are also effects on streamflow in Four and Tenas Creek, which should be explored more with the water load balance model. Goat Creek was not included in the model outputs, although this is acknowledged by the authors. Impacts on Goat Creek should be included in additional assessment of further mitigation strategies.

1.9.2 Response

TML acknowledges the comment. Please see complete response and figures/tables to this comment in the SRK memo [Tenas Project Information Request Responses from Office of the Wet'suwet'en memo, SRK June 2025] Attachment OW-011-1.

Water treatment methods for reducing selenium and nitrate-nitrite were considered in the BAT assessment (Attachment OW-038-3) and include either an active In-situ gravel bed reactor (GBR) or anaerobic moving bed bioreactors (MBBR). The operation of a GBR is described in the BAT assessment report. A GBR is a pond or reservoir that has been backfilled with coarse rock/gravel, covered by an insulating layer (soil and/or organics) and fitted with injection and extraction wells. The operation of a GBR is illustrated in Figure 1-3. Mine water flowing to the injection wells is dosed with a source of easily degradable organic carbon such as methanol or glucose and other nutrients as required. Inside the GBR, microorganisms degrade the organic carbon.

For the Tenas Project, the GBRs would be constructed within the water management ponds using the rock that is already planned to be placed and submerged in the ponds. The treatment system would be operated by pumping mine contact water to the injection wells and dosing the water with a source of organic carbon (shown as amendment delivery system in Figure 1-3).



Source: Attachment OW-038-3

Figure 1-3: Schematic of a Gravel Bed Reactor

The degradation process of carbon consumes oxygen and oxidizes species such as nitrate, ferric iron (Fe^{3+}), selenate (SeO_4^{2-}), and sulphate (SO_4^{2-}) and produces reduced constituents such as ferrous iron (Fe^{2+}), selenite or elemental selenium (SeO_3^{2-}, Se^0) and sulphide (S^{2-}). Sulphide can form insoluble precipitates with dissolved metals such as copper, lead, cadmium, nickel, and zinc, which will be removed in the process. These precipitates will be permanently kept below water at the bottom of the management ponds and are not expected to re-enter the environment due to redox conditions presents.

The mining industry is in the second decade of adopting GBRs. A full-scale GBR with a treatment capacity of 20,000 m^3/day has been constructed at the Rainy River Mine in Ontario and currently operates as primary water treatment for the removal of copper and nitrate. At two coal mines in the Elk Valley in BC, saturated rockfill reactors (SRFs) – a variant of GBRs – are currently used to remove selenium and nitrate from mine water.

Figure 1-5 shows a simplified schematic of an anaerobic MBBR process. Feed water is pumped to the anaerobic bioreactor where organic carbon and nutrients are added. The bioreactor provides sufficient residence time for anaerobic microbes to degrade the organic carbon and complete the reduction process. A post treatment stage consisting of an aerobic bioreactor that removes residual organic carbon and reduced species produced by the anaerobic bioreactor (such as sulphides) treats the effluent from the anaerobic bioreactor. A solid-liquid separation step such as a clarifier, pond and/or filter may be required to remove residual biosolids. From the post treatment stage, the treated water flows to an effluent tank and from there it is discharged to the receiving environment.

Source: Attachment OW-038-3

Figure 1-4: Simplified Schematic of an Anaerobic Biological Treatment Process

Anaerobic bioreactor processes are common and conventional processes for removal or selenium and nitrate from mine water. For nitrate removal, it is the only process in common use. If anaerobic biological treatment were to be implemented for the Tenas Project, both nitrate and selenium would be targeted by the process. However, conventional anaerobic biological treatment would likely not be able to remove the selenium concentrations in untreated effluent that are generally modelled to be less than 0.020 mg/L and often less than 0.010 mg/L. Anaerobic biological treatment can generally only be relied upon to achieve a selenium concentration of 0.010 mg/L. Therefore, a membrane filtration stage would be required to pre-concentrate the untreated discharge before it is treated by the anaerobic biological.

For the Tenas Project, the MBBR process would be operated by pumping mine water from the Tenas Control Pond directly to the treatment plant and then discharging the treated water.

The assumed water treatment performance is based on knowledge of treatment processes that operate at similar sites. Therefore, both the estimates or assumed performances of the treatment processes and the limitations and potential risks associated with treatment processes are based on real-life examples and are therefore reliable for deciding what treatment processes or Best Management Practices are likely to be most suitable for the Tenas Project. However, as discussed in the BAT report (Attachment 6), estimated treatment performances must be verified by site-specific tests. Therefore, a key recommendation, which was adopted by TML, is to initiate pilot trials on site to verify the assumed performance of the selected treatment processes.

The updated water quality model scenario that evaluated water treatment options did assume that water treatment would continue until year 2100. However, the updated water quality model results shows that there would be no exceedances of water quality guidelines in the receiving environment even if no treatment is used during the mine's operations and post-closure phases.

The detailed design information requested by in the review comment will be provided as part of permitting for the two contingency options recommended by the BAT. Detailed design is outside the requirements of an environmental assessment. Implementation and operation of an active water treatment systems will be based on a trigger action response plan developed during permitting. The trigger action response plan will identify appropriate early trigger concentrations or concentration trends in the end of the pipe discharge, in the management and control ponds, and groundwater seepages that will cause TML to begin implementing and operating the treatment systems.

The highest rank options are to continue with the existing Base Case with Best Management Practices incorporated (Final EAC Project Case [2024]) or implement an active In-situ GBR in the management ponds. TML has committed to developing a pilot active In-situ GBR in the CPP Sedimentation Pond or alternate pond to improve this technology's TRL to at least an 8 for the targeted Parameters of Concern prior to the end of Year 4 of the Operation Phase.

As discussed above, in 2025, two studies were completed that evaluated the effects of implementing best management practices and best achievable water treatment technologies (SRK 2025d - Attachment OW-038-2; SRK 2025c - Attachment OW-038-3). Both studies made use of updated water quality model results that included potential effects on streamflow in Four and Tenas Creek and potential effects on Goathorn Creek was also included in the model assessment – see Attachment OW-038-2 for direct impact on Goathorn streamflow.

As requested by OW, TML will discuss appropriate incorporation of the results of forthcoming information related to additional sedimentation ponds to Indigenous interests or Indigenous nations into Project design, monitoring, mitigation, and adaptive management plans.

1.10 IR# OW-047 (IR# 154-1)

1.10.1 Information Request

The Proponent claims that the evaluation of how a 4-meter thickness of PAG left exposed in a management pond would affect water quality is not possible because of the way the pumping system is set up and that the management ponds are always built ahead of PAG placement to ensure that the PAG is below water level. We are concerned that the Proponent dismissed this request saying that under properly managed scenarios this would not be a concern.

We are concerned that the Proponent dismissed this request saying that under properly managed scenarios this would not be a concern. However, it doesn't provide information on the effects of exposed PAG to water quality under scenarios where the management pond techniques fail, such as failure of a pond dam or failure of the pumping system to work as designed. The Proponent must provide this information and include scenarios in the water quality model for estimating impacts where management actions fail, to provide a clear picture of the downstream impacts of PAG under less-than-ideal conditions, but conditions that could possibly occur if there are situations where proper management cannot occur (failure of pumping system or pond dam, or some other instance where a 2m cover of water cannot be maintained).

1.10.2 Response

TML acknowledges the comment. Please see complete response and figures/tables to this comment in the SRK memo [Tenas Project Information Request Responses from Office of the Wet'suwet'en memo, SRK June 2025] Attachment OW-011-1.

Under typical operations, SRK has tested a variety of climate conditions to verify whether water cover could be maintained during operations and in closure through Water and Load Balance Modelling (Attachment OW-038-1). Of note, a scenario considering 3 consecutive 1/200 dry year were applied in the WLBM during the years when water demand is highest (2040-2043). The higher water demand is due to the highest volume of PAG being placed in the West Management Pond during that period and the water is needed to fill the voids contained in the PAG. Water cover under this scenario could be maintained during that time at 0.5m, which was deemed acceptable for operational purposes (higher amount of water covering the PAG layer would prevent safe PAG dumping in the management pond), and up to the maximum water level of 1.0 m. Another scenario considered stochastic climate conditions throughout the life of mine and in post-closure to also test whether water cover could be maintained. Results show that water cover could be maintained throughout operations and in long-term closure (see results in Attachment OW-038-1).

In addition to water balance modelling under relevant climate scenarios, other contingencies exist that would allow to maintain water cover in the ponds:

- Water contained in Tenas Control Pond (operating capacity up to 850,000m3 with an additional contingency storage of 210,300 m^3 to manage large storm events) can be used to top up any management pond that would need it instead of discharging during the open water season (May until October).
- Seepage from the Pit during operations can be redirected to a different management pond when needed.
- Channel 02 (C02) capturing unimpacted runoffs North of the backfill could be redirected to any management pond were it needed.
- Water contained in the voids from the NAG/OVB cover (above the PAG layer) in the management ponds can be pumped to other management ponds when needed (volume of water for NMP, EMP and WMP is 0.840, 3.7 and 7.6 million m^3 respectively).

In case of a pump failure, similar contingencies will be relied upon for the relatively short period of time (likely no more than a few days) it would take to repair or replace the pump, including:

- Gravity seepage from backfill (instead of pumping) can be established to provide extra water cover for any of the active management pond (i.e. management pond with active PAG placement)
- Channel 02 can be redirected by gravity to EMP, which in turn can overflow into NMP
- The Project will operate a network of pumps for conveying water between all three management ponds, which adds redundancy to the system.

In a worst-case scenario, where a pump would have to be replaced and if a spare pump is not kept on site, a rental pump could be mobilized to site in less than one to two weeks. A lack of pumping for such short durations would not lead to the loss of water cover in any of the management pond below the

PAG level. This was illustrated by Figure 1-5 (scenarios with or without pumping from TCP to WMP, which requires the most amount of water to fill PAG voids), which shows that even without pumping from TCP, water cover can be maintained in WMP.

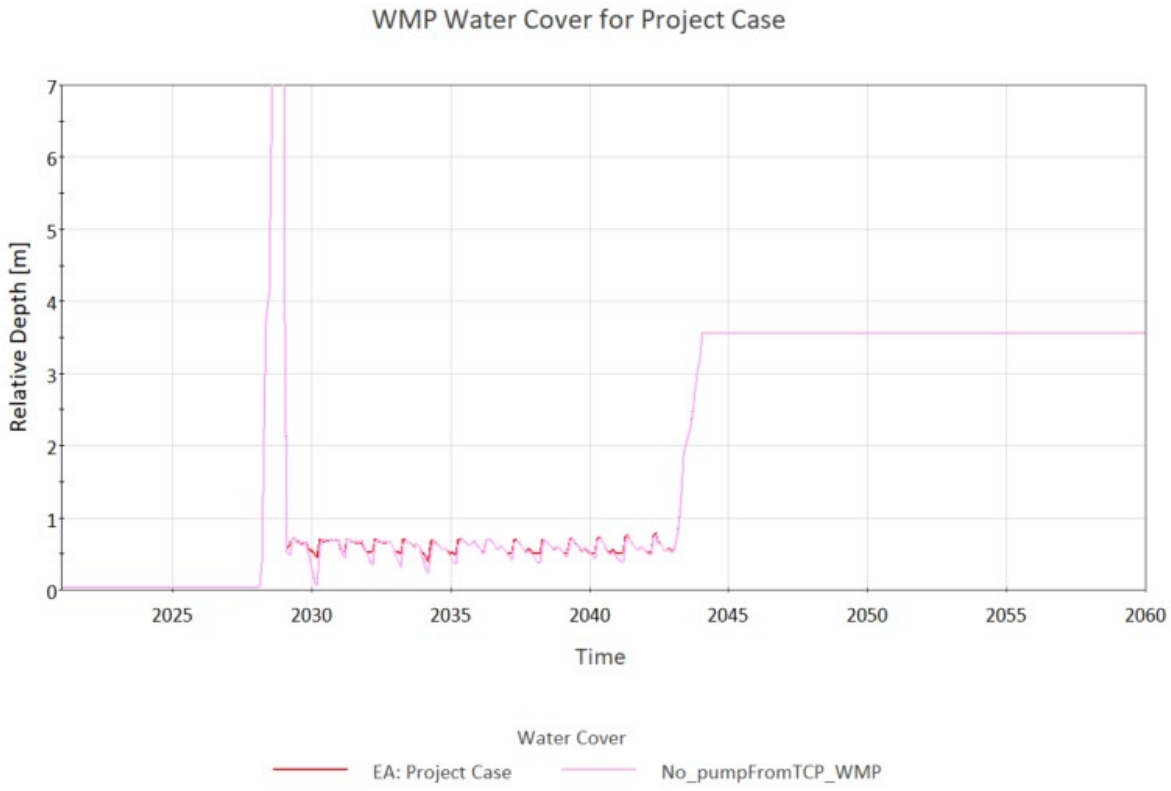


Figure 1-5: Water cover in West Management Pond with (in red) and without (in pink) pumping from Tenas Control Pond.

Dam breaches are very rare occurrences, but plans need to be in place in the very unlikely event that it happens. A dam breach is an extremely serious event that can be extremely hazardous to personnel and the environment.

That said, the risk associated with a detrimental increase in loadings from PAG materials temporarily exposed following a dam breach is very low to negligible, for the following reasons:

- Following a dam breach, priority would be given to repairing the breach and restoring the function of the dam. There is no credible scenario where this would not occur.
- Metal leaching from exposed PAG material is similar to exposed non-acid generating (NAG) material until the PAG begins to produce acid rock drainage (ARD).
- For the PAG material excavated at the Tenas Project, it is estimated that material must be exposed for 3 to 5 years before any ARD begins to develop.
- There is no credible scenario where PAG material would be left exposed for over 3 years following a dam breach to generate ARD.

Therefore, such a scenario will not be modelled.

- Permit conditions that state that PAG must not be exposed to air for more than a given number of months (six months, say) are common and such conditions are enforced by Provincial regulators.

As requested by OW, TML will discuss appropriate incorporation of the results of forthcoming information related to additional sedimentation ponds to Indigenous interests or Indigenous nations into Project design, monitoring, mitigation, and adaptive management plans.

1.11 IR# OW-048 (IR# 154-2)

1.11.1 Information Request

It is unclear where the information is associated with this IR. Within App D they cite a "SRK 2024a" (page 16) with the results of the model output using the various source terms but the reference is not included at the end of the document under "References". Appendix A- WaterBalanceReport... contains source terms but has not been updated to include a sensitivity like requested in the IR. We were unable to review this IR responses as we were unable to find the supporting information. Please provide this information.

1.11.2 Response

The sensitivity requested in the IR# 154-2 included the following request:

IR 154 b): *"Provide a sensitivity in the water quality model to allow PAG exposures on pit wall to understand how exposure of PAG may affect downstream water quality."*

A model sensitivity scenario was developed in this response to address this IR and is described below.

Introduction

In the current mine plan, pit walls are proposed to be covered gradually as mining progresses. It was determined that the only probable scenario where pit walls remain uncovered would be if mining stopped unexpectedly. In the unlikely event that mining stops during operations, it is plausible that some of the pit walls would be exposed for an extended period. Geochemical testing (SRK 2024c) indicates that several of the rock units exposed in the pit walls are potentially acid generating (PAG) and will produce acidity when all of the neutralizing minerals (e.g., carbonates) are consumed. Acidic drainage from the pit walls could therefore develop if they are left uncovered and the wall rock continues to oxidize. A conservative model scenario was developed considering operations to stop at the end of the construction of the East management Pont (EMP – Year 8 in the mine plan), as it represents the largest exposed pit wall surface area that would remain exposed if no other mitigation measures were implemented prior to the unplanned cessation of operations. It was assumed that it would take 15 years to resume operations and all pit wall surfaces that were not covered prior to Year 8 would remain uncovered during this period. If mining stops at that time, a pit lake would start forming

in the backfill collecting different inflows including the runoff from meteoric water flowing over the uncovered pit wall areas.

The following subsections describe the geochemical conceptual model, model development and the water quality results for the geochemical pit lake model.

Pit Lake Geochemical Conceptual

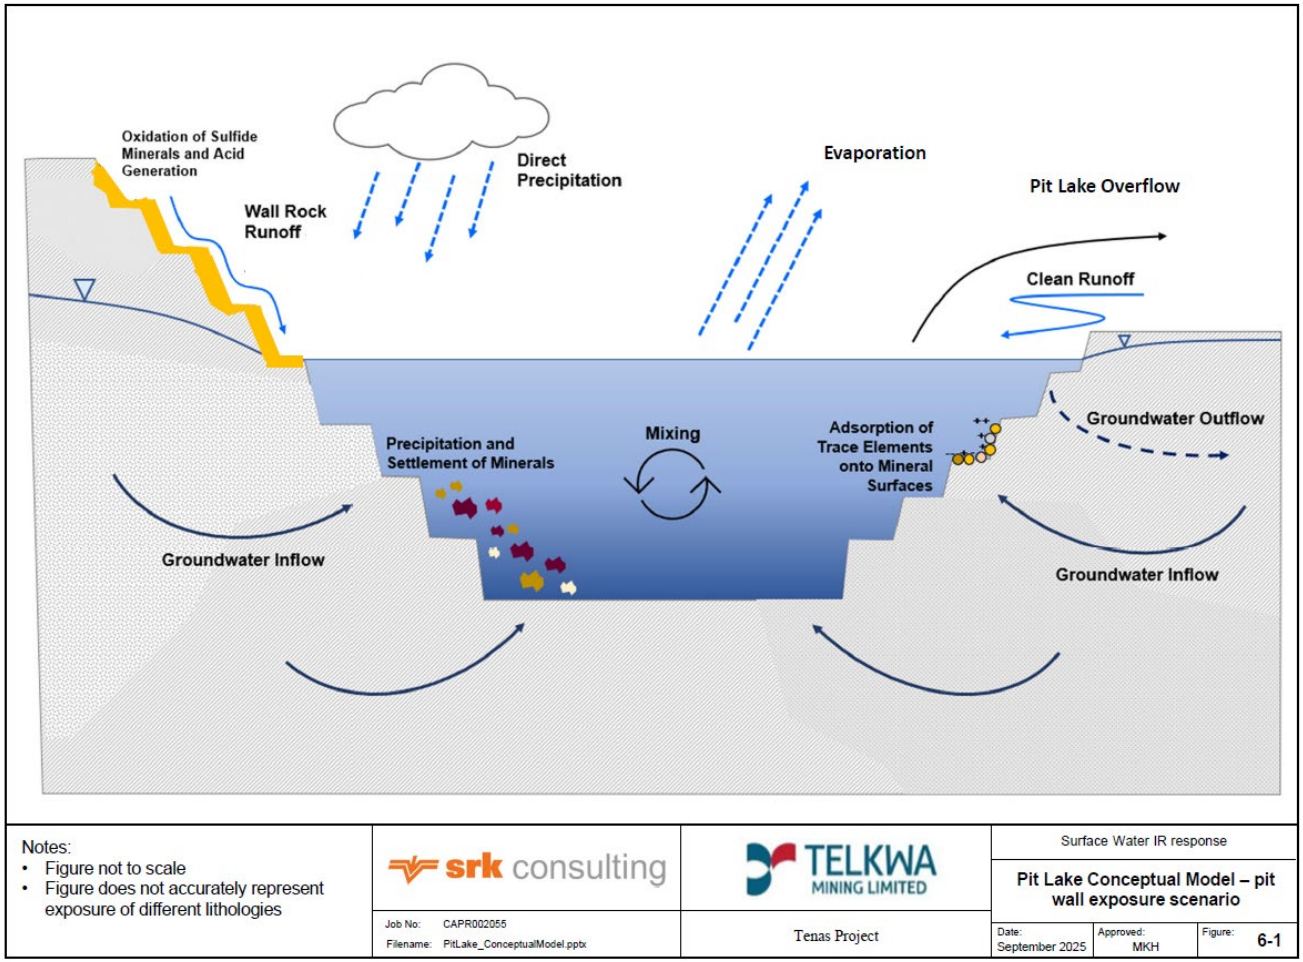
Mining of the Tenas Project will result in open pit walls that are exposed to atmospheric oxygen, which would continue to occur if they remain uncovered due to mining stopping unexpectedly. When exposed to oxygen, sulfides that are present in the open pit wall rock will oxidize according to reaction 1 (Rxn 1) producing sulfate, acidity, ferrous iron, and release of trace chalcophile elements.

$$FeS_{2\,(s)} + \frac{7}{2}O_{2\,(g)} + H_2O_{\,(l)} \leftrightarrow Fe^{2+}{}_{(aq)} + 2SO_4^{2-}{}_{(aq)} + 2H^+{}_{(aq)} \text{ (Rxn 1)}$$

Under oxidizing conditions, ferrous iron liberated during sulfide oxidation will subsequently oxidize to ferric iron in neutral pH producing additional acidity according to the following reaction:

$$Fe^{2+}{}_{(aq)} + \frac{1}{4}O_{2\,(g)} + 2\frac{1}{2}H_2O_{\,(l)} \leftrightarrow Fe(OH)_{3\,(s)} + 2H^+{}_{(aq)} \text{ (Rxn 2)}$$

Although oxidation of mine rock for the Tenas Project will release acidity, acidic conditions are not predicted to occur immediately since these materials also contain carbonate minerals that will neutralize the acid according to the following reactions:



$$CaCO_{3(s)} + H^+{}_{(aq)} \leftrightarrow HCO_3^-{}_{(aq)} + Ca^{2+}{}_{(aq)} \text{ (Rxn 3)}$$

$$CaCO_{3(s)} + 2H^+{}_{(aq)} \leftrightarrow H_2CO_{3(aq)} + Ca^{2+}{}_{(aq)} \text{ (Rxn 4)}$$

Depletion calculations (SRK 2024c) indicate that the lag times to acid generation are on the order of years (>5 years based on the average bulk rock properties). The lag time to acid generation prediction based on HCTs was confirmed by the barrel testing results. Barrel 6, which is a composite sample of rock from Zones 6 and 7, became acid generating in October 2023, four years after the barrel program was initiated. SRK (2024c) indicated that these zones were non-PAG based on their average bulk geochemical properties. However, the weighted barrel 6's NPR (0.5) was more closely aligned with the minimum and P5 NPR observed for these zones (see Table 4 in SRK (2024c)). The lag times to the onset of acid generation based on the Zone 6 and 7 minimum NPRs ranged from 3 to 5 years. To provide a conservative prediction of pit lake water quality, onset of acidic conditions of pit wall PAG rock was assumed to commence in Year 4 of the model.

Once mining stops, a lake will form as the pit fills with water, which will reduce the exposure of pit walls to atmospheric oxygen. Submerged wall rock will become isolated from atmospheric oxygen minimizing oxidation of inundated wall rock. A high wall will exist above the pit lake composed of approximately 30% of PAG-rock which will be acid generating once acid neutralizing minerals are consumed; the remainder of the pit walls are composed of non-PAG rock and overburden. It is assumed that the overburden and the non-PAG rock will be weathered containing limited sulfide and will not produce acidic conditions. Soluble oxidation products will be flushed from exposed open pit wall surfaces in the high wall by meteoric water contacting and mix together with other inflows (e.g., groundwater inflow) in the pit lake (Figure 1-6).

If the pit lake remains alkaline, several secondary mineral species will become supersaturated in the pit lake and precipitate from solution. Sorption of other element species will also occur which can also limit concentrations of these constituents. If the lake becomes acidic, the solubility of several dissolved species (e.g., sulfate) will increase. Mass will also be lost from the pit lake through advective outflows.

Source: https://srk.sharepoint.com/sites/NACAPR002055/Internal/Water%20Balance%20Modelling/Model/202309_Updated%20EA%20Case/PAG_Pitwall/Source_term_dev/Figure_OW48_1._PitLakeConceptual_modelpptx.pptx?web=1

Figure 1-6: Pit lake conceptual model

Geochemical Pit Lake Model Development and Inputs

A geochemical model was developed in the publicly available speciation and mass transfer code PHREEQC v.3 (Parkhurst and Appelo 1999) to evaluate pit lake water quality if mining stopped at the end of the PAG placement in the East Management Pond (EMP) in 2029. It was assumed that it would take 15 years to resume operations and all pit wall surfaces that were not covered prior to Year 8 would remain uncovered during this period.

Water balance modelling indicates that a lake will form in the mined-out pit if operations were to cease in Year 8 of the mine plan. Based on an average climate scenario, the open pit will require 15 years to reach its maximum storage capacity of 34 Mm^3 from pit wall runoff, groundwater inflows, direct precipitation, and other upstream catchments such as non-contact runoff and backfill seepage. Once the pit lake has reached its maximum water storage capacity, approximately 450,000 m^3/year is modelled to discharge to the West Management Pond, which eventually would discharge to Goathorn Creek on top of the regular discharge from the Tenas Project.

The geochemical model was developed to account for mixing of water flowing over the different zones of the pit walls, as well as the mixing of different water sources within the pit lake (e.g., groundwater inflows, etc.) The following assumptions were included in the water balance model to simulate these conditions:

- Catchments in the water balance model (SRK 2025b) for 2029 (Year 8) were assumed to be constant for the remainder of the scenario simulation, as mining is assumed to have stopped.
- Water from the Tenas Control Pond and the unimpacted catchment captured by the channel C02 around the East Management Pond would be diverted towards the pit lake during freshet, instead of into Four Creek, to expedite flooding of the pit to minimize oxidation of exposed wall surfaces.
- Groundwater inflows were considered constant based on prior groundwater modelling (SRK 2024b).

The water quality model was set up using annual timesteps over the shut-down period of 16 years. At each timestep, inflows to the pit were assigned a source term water quality and mixed based on their relative proportions using Equation 1 (EQ1):

$$C_{lake} = \frac{V_{lake,t_i} \times C_{lake,t_i} + \sum_{i=1}^{n} Q_i \times C_i - C_{lake,t-1} \times Q_{out}}{V_{lake,t_{i+1}} - E_{lake,t_i}} \quad \text{Eq 1}$$

Where:

- C_{lake}: predicted concentration in the pit lake
- $V_{lake,\ ti}$: volume of the pit lake at time i
- $V_{lake,\ ti+1}$: volume of the pit lake at the subsequent timestep
- $E_{lake,\ ti}$: evaporation from the pit lake at time i
- C_i: concentration of each inflow to the pit lake at time i
- Q_i: inflow volume to the pit lake from input source i

- $C_{lake,t-1}$: concentration of the pit lake at the previous timestep
- Q_{out}: outflow from the pit lake

Following mixing, supersaturated mineral phases were identified and selected for equilibration in the model based on commonly observed secondary mineral phases at mine sites (SRK 2024a). Sorption to ferrihydrite was considered using the default values of Dzombak and Morel (1990) which may limit parameters that form oxyanions (e.g. arsenic and selenium) and other trace elements from persisting in solution, should ferrihydrite precipitate in the pit lake. The lake was assumed to be fully mixed and in equilibrium with the atmosphere under oxidizing conditions. To account for this in the model, the redox potential (Eh) was fixed at 550 millivolts (pe=10). After each timestep, the solution was saved and brought forward to the next timestep as the input for existing lake chemistry.

Exposed wall rock surfaces will produce oxidative load that will be flushed by meteoric water. An annual wall drainage water quality was estimated by calculating the mass released from each stratigraphic zone using Equation 2:

$$C_{j,t} = \frac{L_j \times M_t}{Q_t} \qquad \textbf{Eq 2}$$

Where:

- Cj,t is the concentration of parameter j at time t
- Lj is the scaled field barrel release rate of parameter j
- Mt is the cumulative reactive mass of rock exposed along pit walls at time t
- Qt is the volume of water in contact with the pit walls at time t prorated to the surface area of each zone

The predicted water qualities for each stratigraphic zone were subsequently mixed in their relative proportions determined based on the site wide water balance model. As noted above, SRK (2024c) indicates that PAG rock will produce acidity after neutralizing minerals have been consumed by acid produced through sulfide oxidation. The timing to onset of acidic conditions is dependent on the available neutralization potential and rock sulfide concentrations and is variable by zone (see SRK 2024c). In the wall rock runoff source term derivation, all PAG zones were assumed to become acidic after four years. This represents the minimum time to acid onset for the average bulk properties of PAG rock in Zone 4 (SRK 2024c) and provides a conservative estimate of the wall rock runoff since the timing to the onset of acidic conditions is longer for all other stratigraphic zones and these are therefore assumed to become acidic much sooner than they would in reality. The predicted wall rock annual concentrations using Equation 2 were subsequently equilibrated using the geochemical modeling code PHREEQC to evaluate if the concentrations would be constrained through precipitation of secondary minerals and adsorption surfaces.

The model was set up to calculate water quality for the following constituents:

- General Chemistry: pH, alkalinity
- Major Ions: calcium, magnesium, sodium, potassium, sulfate, chloride
- Trace Elements (dissolved): aluminum, antimony, arsenic, barium, boron, cadmium, chromium, cobalt, copper, iron, lead, lithium, manganese, mercury, molybdenum, nickel, phosphorus, selenium, strontium, thallium, tin, uranium, vanadium and zinc.

Total metals concentrations were calculated based on the assumption of a maximum TSS discharge of 35 mg/L (SRK 2024a and SRK 2025b), and proportions of TSS comprised by various elements based on whole rock analysis for non-PAG and PAG rock. Total element concentrations were calculated by adding dissolved and particulate concentrations.

The following additional inputs and assumptions were included in the pit lake geochemical model:

- A damaged rock zone depth of 2m and a fracture frequency of 10% was used to calculate the reactive mass from blasted surfaces.
- A damaged rock zone depth of 0.1m and a fracture frequency of 10% was used to calculate the reactive mass load from free dig areas.
- Water balance model flows recharging the pit lake (i.e., direct precipitation, pumped flows from TCP, unimpacted catchment runoff from channel C02) were based on an average climate scenario (SRK 2025b).
- Yearly average water quality model results for Tenas Control Pond (in 2029) (SRK 2025b) were used to represent the quality of water pumped from the Tenas Control Pond to the pit lake.
- Background surface water and groundwater quality for unimpacted catchments and groundwater inflows (SRK 2025b), respectively, were used to represent the quality of these sources to the pit lake.
- Backfill inflow and load were not considered in this scenario as it was considered insignificant (no seepage yet from backfill, and small amount of rock volume in backfill)
- Load from talus on the pit benches was not included in the model.
- An alkalinity of 75 mg/L was assumed for non-PAG rock pit wall runoff, as well as for the Tenas Control Pond and C02 inflows.

The fully-mixed equilibrated concentrations were modelled between 2029 and 2045 (16 years in total).

Pit Lake Model Results

The pit lake model results show that the pit lake water does not become acidic after 16 years, despite the acidification of the PAG zones in the pit wall. This is due to the relatively low contribution of PAG zones (30%) in the total pit wall runoff inflow. Additionally, the proportion of wall rock runoff to other pit lake inflows decreases from 20% to less than 10% as the pit lake floods. After 16 years, concentrations of most parameters begin to reach steady-state. An increase in concentrations of sulfate as well as some metals were observed over the modelled period, such as iron, cadmium, cobalt, dissolved nickel and zinc, due to the acidification of the PAG zones in the pit wall. Other metals decreased over time (e.g. arsenic from sorption to precipitated ferrihydrite). Copper and aluminum also decreased over time, though the decrease in concentrations was less pronounced than for arsenic. pH remained

around 8.5 throughout the simulation, with a slight decrease (<0.2 pH units) over time, which would be explained by the acidification of the pit wall runoffs in Year 4 of the Pit Lake model. Trends over time for all dissolved and totals parameter concentrations can be found in Attachment OW-048-1.

The predicted pit lake water quality in 2045 (Year 16 of the Pit Lake model simulation) is presented in Table 1-6. Predicted concentrations are compared against water quality guidelines for Goathorn Creek since this will be the tributary the lake will be dewatered to when mining resumes. The following constituents were screened to be parameters of concern (POCs) based on the comparison to water quality guidelines in Goathorn Creek (Table 1-6): sulfate, total aluminum, total chromium, dissolved cobalt, total iron, total molybdenum, dissolved nickel, total selenium, total thallium and dissolved zinc. These parameters had been identified previously as POCs in the Best Achievable Technology Assessment (BAT) [SRK 2025d][1]. The source of these parameters is the acidification of the PAG zones in the pit wall after four years of being left exposed. However, because of the small contribution of pit wall runoff to the total inflows, the pit lake water remains neutral (pH ~8.5) throughout the simulation.

[1] The BAT report did not have total thallium as a POC as it was issued prior to the latest WQG update in March 2025.

Table 1-6: Summary of predicted pit lake water quality compared against Goathorn Creek water quality guidelines

Pit Lake Dewatering Evaluation

For operations to resume, the pit lake would need to be dewatered. To evaluate the impact of dewatering on Goathorn Creek during the open water season, three different dewatering scenarios were included in mass balance calculations with the following inputs:

- Seasonal background 50th percentile concentrations for Goathorn Creek (open-water season [SRK 2025b])

- Water quality model results for the pit lake in 2045 (Year 16).
- Pre-mining Goathorn Creek flows calculated by the rainfall-runoff model in the water balance (SRK 2025b)
- Four different pit lake discharge rates (4 scenarios) of 5,000, 10,000, 15,000, and 30,000 m^3/d during the open-water season (May until October)

Model results for the above modelled scenarios are summarized in Table 1-7 to Tabe 1-11, and represent the maximum monthly concentration after mixing with streamflow in Goathorn Creek. The model results showed a few exceedances of water quality guidelines in all four discharge rate scenarios, including dissolved cobalt, dissolved copper, dissolved nickel, total selenium, total thallium, and dissolved zinc. Of note, the dissolved copper exceedance is expected to be driven by high background concentrations, as highlighted by SRK (2025c), and the discharge from the pit lake contributes very marginal load to the creek (i.e. less than 1% of load in the stream). The only other exceedance that occurs for all months during the open water season is dissolved cobalt (under the highest discharge rate of 30,000 m^3/d), but the remainder of the exceedances are expected in the fall, mainly in September, when dilution capacity is reduced. Detailed exceedances for each month are provided in Table 1-8 to Tabe 1-11 for each discharge rate scenario. These results indicate that a variable discharge rate would be preferred to minimize any exceedances during the open-water season. A detailed discharge management plan would be developed, and the discharge rate at which the pit lake is dewatered would take into account the available dilution capacity in the stream, as well as available contingencies in order to resume Operations. Several contingencies are available to further mitigate these potential exceedances:

- Variable discharge rates, with increasing discharge rates during peak based on available dilution capacity in the stream.
- Use dilution from other sources, such as water from TCP, as well as unimpacted water from C02 channel to mix with the pit lake effluent to lower the impact of the dewatering discharge from the pit lake into the stream.
- In the very unlikely possibility that the pit lake became acidic, despite this model scenario results, lime could be considered to manage pH and other problematic metal concentrations.

As requested by OW, TML will discuss appropriate incorporation of the results of forthcoming information related to additional Project scenarios to Indigenous interests or Indigenous nations into Project design, monitoring, mitigation, and adaptive management plans.

Table 1-7: Monthly maximum model result concentrations in Goathorn Creek for three discharge rates: 5,000, 10,000 and 15,000m3/d, compared against baseline concentrations and water quality guidelines.

Note: 1 Parameters exceeding the water quality guidelines are highlighted in red.

2 Nitrogen species were not modelled in this Pit Lake scenario as the backfill seepage is insignificant in this scenario based on prior modelling (SRK 2025b). Other parameters that were not modelled were fluoride, beryllium and silver as they were no sources based on the barrel release rates.

3 These model results only apply for the open-water season (from May until October), and it was found that the monthly maximum was found for September for all parameters, due to lower flows at the end of summer.

To help OW better assess how TML is protecting the Environmental Flow Needs, provide details on how and/or TML will manage flows to avoid high risk levels and maintain environmental flow needs (reduction of <10% of mean average by season) during operation. To help OW better assess how TML is protecting the Environmental Flow Needs, provide details on how and/or TML will manage flows to avoid high risk levels and maintain environmental flow needs (reduction of <10% of mean average by season) during operation.

Commit to appropriate planning for contaminant areas, which requires a proactive approach to mitigating contaminant leakage (rather than attempting to mitigate once problems have been identified);

1.12.2 Response

TML acknowledges the comment. Please see complete response and figures/tables to this comment in the SRK memo [Tenas Project Information Request Responses from Office of the Wet'suwet'en memo, SRK June 2025] Attachment OW-011-1.

TML is committed to developing detailed liner designs, construction methodologies and monitoring to ensure that the liner systems installed for the management and control ponds limit seepage to the modelled values provided in the Final Water and Load Balance Report. Please refer to Attachment OW-118-1 for the Liner Design Report completed by SRK (SRK 2024d).

As requested by OW, TML will consider any forthcoming information from the OW and the Houses and, as appropriate, will consider how this information informs Project design, monitoring, mitigation, and adaptive management plans.

1.13 IR# OW-120 (New IR)

1.13.1 Information Request

To help OW better assess how TML is protecting the Environmental Flow Needs, provide details on how and/or TML will manage flows to avoid high risk levels and maintain environmental flow needs (reduction of <10% of mean average by season) during operation. To help OW better assess how TML is protecting the Environmental Flow Needs, provide details on how and/or TML will manage flows to avoid high risk levels and maintain environmental flow needs (reduction of <10% of mean average by season) during operation.

Consider the appropriateness of water and load balance models and correct seepage migration rates and timing of peak contaminant concentrations;

1.13.2 Response

TML acknowledges the comment. Please see complete response and figures/tables to this comment in the SRK memo [Tenas Project Information Request Responses from Office of the Wet'suwet'en memo, SRK June 2025] Attachment OW-011-1.

SRK is addressing the last part of this IR related to "Consider the appropriateness of water and load balance models and correct seepage migration rates and timing of peak contaminant concentrations;".

SRK uses standard and accepted practices that integrate inputs from regional groundwater models into the water and load balance model to represent the changes from mine activity to the stream flow and water quality, combining groundwater inputs and rainfall runoff model for each creek. More information on how these are linked together can be found in IR OW-038 and in Attachment OW-038-1, and OW-038-4.

As requested by OW, TML will consider any forthcoming information from the OW and the Houses and, as appropriate, will consider how this information informs Project design, monitoring, mitigation, and adaptive management plans.

1.14 IR# OW-122 (New IR)

1.14.1 Information Request

For Surface Water, Ground Water, and Aquatic Resources VCs, TML must:

Provide the cited document in Appendix D: "SRK 2024a" (page 16), which is missing from the end of the document under "References". Appendix A- Water and Load Balance Model Report.

1.14.2 Response

TML acknowledges the comment. Please see complete response and figures/tables to this comment in the SRK memo [Tenas Project Information Request Responses from Office of the Wet'suwet'en memo, SRK June 2025] Attachment OW-011-1.

TML acknowledges the comment. Please see response to OW-039.

Please refer to Attachment OW-038-1 for the Final Water and Load Balance Report.

As requested by OW, TML will consider any forthcoming information from the OW and the Houses and, as appropriate, will consider how this information informs Project design, monitoring, mitigation, and adaptive management plans.

1.15 IR# OW-124 (New IR)

1.15.1 Information Request

For Surface Water, Ground Water, and Aquatic Resources VCs, TML must:

Provide additional information and figures for the Water and Load Balance Model Report that we have not been able to locate, including:

-Final figures presented in "Attachment IR 356-1 as the attachment with that name at the end of App F contains no information;

-Figures for each of the requested scenarios in the IR (Tributary receiving discharge above confluence with Goathorn Creek, and Goathorn Creek below confluence with tributary receiving discharge) and projected water quality from baseline through to post-closure;

-Updated figures from the WLBM report (Fig 2.2-2.4 of App 4.3) that originally showed incorrect connections of the three creeks (Four Creek, Tenas Creek, Goathorn Creek); and

-TML's response to the IR, labelled "Final EA Water and Load Balance results", or Attachment IR 356-1.

1.15.2 Response

TML acknowledges the comment. Please see complete response and figures/tables to this comment in the SRK memo [Tenas Project Information Request Responses from Office of the Wet'suwet'en memo, SRK June 2025] Attachment OW-011-1.

Please see responses to OW-040 and OW-041.

As requested by OW, TML will consider any forthcoming information from the OW and the Houses and, as appropriate, will consider how this information informs Project design, monitoring, mitigation, and adaptive management plans.

1.16 IR# OW-125 (New IR)

1.16.1 Information Request

For Surface Water, Ground Water, and Aquatic Resources VCs, TML must:

Use climate change predictions in the understanding of potential impacts throughout the operation and post-closure periods (e.g., changes in flow and changes in stream temperature due to changes in flow and air temperature).

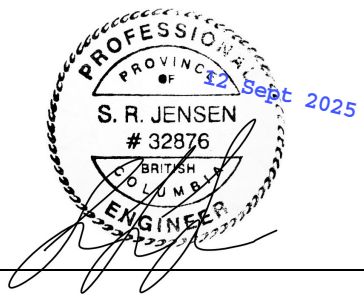
1.16.2 Response

TML acknowledges the comment. Please see complete response and figures/tables to this comment in the SRK memo [Tenas Project Information Request Responses from Office of the Wet'suwet'en memo, SRK June 2025] Attachment OW-011-1.

Climate change is included in the Water and Load Balance model for the Project using modelled climate rate of change to precipitation and temperature as inputs to the WLBM, according to the latest IPCC report (AR6) and latest available GCMs (global circulation models), as described in Attachments OW-125-1 and OW-038-1. It also includes climate change impacts to runoff (in the streams) and evaporation. An excerpt from the report (Attachment OW-125-1) describing the work follows:

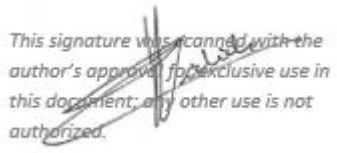
"This climate change assessment was based on results from GCMs included in CMIP6 and the corresponding IPCC Sixth Assessment Report (AR6) (Masson-Delmotte, 2021)."

"Climate change scenarios for RCP4.5, RCP6.5 and RCP8.5 were evaluated for the Project Area. The effects of the RCP4.5 scenario were used to generate mean annual and monthly temperature and precipitation correction factors, which also affect runoff and evaporation rates…"



Climate (daily precipitation and temperature) was adjusted in the WLBM until the end of the model simulation (2100) with adjustment factors as described in Attachment OW-038-1. Further, climate inputs are drivers of the streamflow modeling in the water balance model, through the rainfall-runoff models for each stream. Effects of climate change on streamflow is therefore carried forward through the adjustments to temperature and precipitation.

Change in temperature in the streams was evaluated in a mass balance approach, external to the WLBM, based on baseline temperature data for Goathorn Creek and assuming that temperature for the effluent water is equal to the air temperature (corresponding to the maximum air temperature from the WLBM). The maximum air temperature from the WLBM accounts for climate change. The use of air temperature as a proxy for effluent temperature is considered conservative and therefore the change in temperature recorded in the creek is expected to be conservative as well.



As requested by OW, TML will consider any forthcoming information from the OW and the Houses and, as appropriate, will consider how this information informs Project design, monitoring, mitigation, and adaptive management plans.

Executive Summary

A water and load balance model has been developed in support of the BC Environmental Assessment Certificate Application (EA) and joint application submission for a BC *Mines Act* permit and BC *Environmental Management Act* discharge permit for the Tenas Project (the Project) in northwest British Columbia. The Project consists of an open pit, a series of management ponds which will contain submerged potentially acid-generating materials, a coal processing plant, water management infrastructure, ancillary facilities, and rail infrastructure. The mine will take 1.5 years to construct and will operate for 21 years. Decommissioning and reclamation will take approximately 4 years with a further 50 years being assigned to the Post-closure phase.

Inputs to the model include groundwater modeling results, climate and hydrology datasets, performance and Operations of mining elements, water management infrastructure, catchment areas, geochemical source terms and baseline water quality. Model results provide expected and worst-case water quantity and quality, during and after mining is complete. Sensitivity analyses conducted in the model are used to understand what variables the model results are most sensitive to. Where applicable, model results were calibrated using baseline information. Results are summarized in terms of water quantity and quality changes to the surrounding watercourses which may be expected to occur in Construction, Operation, Decommissioning and Reclamation, and Post-closure phases.

Modeling was completed in GoldSim software package, which uses a daily time step and reports monthly average results. Hydrologic components of the model were calibrated to regional and local streamflow datasets and encompass interactions between surface water and groundwater. Streamflow is generated on a daily timestep based on precipitation and temperature datasets, which include an orographic gradient adjustment. Both precipitation and temperature have additional adjustments included to account for climate change, which projects an increase in temperature year-round and an increase in precipitation for most months, through the year 2100.

The load balance component is based on the conservation of mass, assuming complete mixing for each prediction node and time step. Geochemical characterization results are included to estimate mass of constituents released per mass of mine rock stored in various mine waste facilities such as a backfill in the open pit. The in-stream water quality is calculated based on the mixing of Project discharge with background loading estimated from baseline monitoring of surface and groundwater quality.

Within the proposed Project area, the model simulates the flux of water and mass. Monthly withdrawals of water because of diverted catchment areas and monthly discharges into the downstream environment are estimated. A further 2.5% of water was withdrawn from Goathorn Creek to evaluate the contingency of withdrawing water for Project demands though not required by the model. Prediction nodes were selected to represent expected conditions in the downstream environment and are evaluated in relation to a baseline condition, which estimates streamflow and quality through 2100 without influence of the proposed Project.

Multiple Project alternative assessment cases were selected to understand the range of potential effects from the Project throughout the life of mine. These cases incorporate variability in hydrologic conditions, groundwater conditions and geochemical source terms. The main results reported describe the Project

Case, which incorporates Project design mitigation measures and expected inputs for geochemical source terms and average hydrology. Results for each alternative assessment case are presented in Appendix F (water quantity) and Appendix G (water quality). The Project Case model conditions are incorporated to simulate the expected, or most likely estimate based on available information. Where input assumptions are uncertain, more conservative assumptions were made. Preliminary model results were used to develop mitigation measures which were applied in subsequent model versions as appropriate.

A prior report was submitted as part of the 2022 EAC application, and while the main structure and assumptions of the model remained the same, the following changes to inputs were made:

- Review and update of water quality guidelines with respect to recent provincial publications, used for the screening of water quality modeling results and identification of potential effects.
- Review and update the Tenas Project climatic records, based on additional data from the local station since the development of the EA baseline report (SRK 2024a).
- Review of streamflow model performance against measurements collected in 2022, along with implementation of an alternative dynamic streamflow model.
- In addition to climate records and streamflows, the climate change model has been updated to match current approved scientific requirements. All three updates are summarized in the updated hydrometric report (SRK 2024a).
- Update of background source terms incorporating seasonality (summer and winter conditions) in the model based on updated baseline data.
- Update of geochemical source terms related to barrel monitoring undertaken over the past four years which was used for quality predictions (SRK 2024b).
- Update of source terms related to the non-PAG backfill in the open pit to account for methodology of constructing this backfill in thinner lifts from the bottom up and progressive reclamation through the addition of overburden and surface soil (topsoil) covers (Okane, 2024).
- Review and update to the groundwater model which led to updated calculations to estimate the load in the creeks through groundwater seepage from the Project (SRK 2024c).

Project Results

- Sufficient water is expected within the Project area to maintain the minimum 0.5 m water cover above PAG materials within 6 months of rock placement on average, and 1.5 m of water cover throughout the rest of Operations and during Post-closure.
- Process and potable water demand as well as water to mix with sewage effluent will be met throughout operation based on available water in the Open Pit sump, keeping Tenas Control Pond as a contingency.
- Project discharge ranging from 9,000 m^3/day to 24,700 m^3/day from the Tenas Control Pond will include pumped flows and overflows via the spillway into a tributary of Goathorn Creek. Additional discharge to the Bulkley River is anticipated from the Rail Infrastructure Sedimentation Pond at a

rate of up to 260 m^3/day. In closure, Project discharge will occur from the North Management Pond to the tributary of Goathorn Creek at a rate of up to 28,800 m^3/day.

- Discharging facilities (Rail Infrastructure Sedimentation Pond, Tenas Control Pond and North Management Pond) have the following parameters of concern identified in their effluent (80% of corresponding water quality guideline calculated for the receiving stream) during active discharge periods under Project Case conditions: nitrate-nitrogen, nitrite-nitrogen, sulfate, total aluminum, dissolved cadmium, dissolved cobalt, dissolved copper, total iron, total molybdenum, total nickel, total selenium, total thallium, dissolved zinc.

Receiving Environment Results

Water Quantity

Effects to surface water quantity were evaluated based on relative change over baseline conditions. A parallel pre-mining model was run in tandem with each assessment case using baseline conditions, and monthly percent change was calculated by comparing the proposed conditions with mining relative to pre-mining results. Results are summarized in relation to changes to mean annual discharge, monthly discharge, and low and high flows.

- Four Creek prediction nodes, including WQ03, WQS21, WQS20 and WQS03DS, show as high as 37% reduction and as high as 48% increase to monthly streamflow during operation. These results reflect the maximum change to catchment area and baseflow because of mining Operations. Diversion channels and mine plan optimizations help to reduce the Project footprint as much as possible. However, the open pit and the Management Ponds continue to route water that would have otherwise drained to Four Creek towards Goathorn Creek via the Tenas Control Pond discharge, resulting in a reduction of catchment area, while the C02 channel diversion results in an increase in catchment area in portions of Four Creek.
- Tenas Creek is expected to experience up to a 10% reduction in monthly streamflow during low flow periods (April and August) during operation because of open pit groundwater drawdown and catchment area reductions. The seepage from Management Ponds counters this effect by the end of operation and into Post-closure, resulting in a long-term change to mean annual discharge of less than 6%.
- Goathorn Creek flows are expected to be reduced by up to 8% during low flow months in operation. Flows downstream of the Project discharge are expected to increase by up to 6% in operation during high flow months and 11% in Post-closure due to routing of water through the Project infrastructure that would otherwise have reported to the Tenas Creek catchment. The change to mean annual discharge is less than a 3% reduction in operation and Post-closure.
- The Project may reduce monthly average flows in the Telkwa River downstream of Goathorn Creek by less than 2% in operation and an increase of 1% in Post-closure due to seepage from Management Ponds. Bulkley River monthly streamflow changes are negligible (less than 0.1% change during any phase of the Project).

Water Quality

Effects to surface water quality were evaluated based on screening against selected water quality guidelines (WQG) as well as variability within the historical monitoring record. Baseline monitoring data show the streams are naturally elevated for total aluminum, total iron, and dissolved copper and have experienced periods above the WQG values. Exceedances for modelled results are summarized by model cases and stream:

Project Case

Under expected conditions, in terms of hydrology, groundwater and source terms:

- Exceedances of the dissolved cobalt WQG may occur in Four Creek in Closure only for a few years (4 years) in Post-closure.
- Exceedances for dissolved copper WQG may occur in Goathorn Creek in winter and summer during the Operations and Post-closure phases, but results are within the natural variability of baseline monitoring data (i.e., less than the 95th percentile from baseline datasets). Because these exceedances are driven by naturally elevated concentrations of dissolved copper in the background, the concentrations do not decrease over time.
- In Telkwa River, exceedances of the total aluminum and dissolved copper WQG occur in summer months during the Operations phase in the Project Case. The results for total aluminum are less than the natural variability recorded in the baseline monitoring data (i.e. less than the 95th percentile from baseline datasets). Exceedances of the WQG of dissolved copper are experienced in summer throughout operation phase only but results are less than the 50th percentile from baseline data.

Alternative Project Case 2 (High Source terms)

Under the upper-case geochemical source term conditions, the following water quality results are noted:

- The total selenium WQG is exceeded in both summer and winter months during Post-closure by up to 1.6 times in Four Creek. The long-term winter and summer results in 2100 are below the WQG.
- The dissolved cobalt WQG is exceeded in both summer (maximum monthly only) and winter months (monthly maximum and average) up to 4.3 times the guideline in Four Creek.
- The nitrite-nitrogen WQG is exceeded in winter months by up to 1.7 times the guideline in Four Creek with some exceedances in summer months.
- The total selenium WQG is exceeded in Tenas Creek at downstream prediction nodes WQS22 and WQS04 in winter months during Post-closure by up to 1.5 times the guideline.
- The dissolved cobalt WQG is exceeded in winter months only up to 1.8 times the guideline in the downstream prediction nodes from the Project in Tenas Creek.
- Exceedances for total selenium by up to 1.5 times the WQG in Goathorn Creek, occurring only in Post-closure during the winter months. These exceedances are below the WQG by 2100.

- Exceedances for dissolved cobalt by up to 1.1 times in prediction nodes in Goathorn Creek during Operations due to higher discharge from the Project, and in WQS05 (most downstream node) in Closure up to 1.1 times the guideline due to groundwater seepage.

Alternative Project Case 5 (Low flows)

Under 7Q10 low flow conditions, the following water quality results are noted:

- The total selenium WQG is exceeded in both summer and winter months during Post-closure by up to 2.7 times in Four Creek. The long-term winter and summer results in 2100 are below the guideline.
- The nitrite-nitrogen WQG is exceeded in winter months by up to 2.9 times the guideline in Four Creek with some exceedances in summer months.

Other observations from the water quality modelling results:

- Groundwater seepage from management ponds into portions of Tenas, Goathorn, and Four Creek is expected to increase the total dissolved solids concentration and conductivity of the stream above baseline levels. In Tenas and Four creeks, the model results are within 10% of the 95th percentile from baseline monitoring. In lower reaches of Goathorn Creek, however, the model results are greater than 10% above the 95th percentile from baseline monitoring. These changes to Goathorn Creek persist into steady-state conditions.

The effects to both stream water quantity and quality were further evaluated in terms of the affected area within the spatial boundaries of the Project, including the local stream watersheds, the local study area (LSA) and the regional study area (RSA).

- In terms of water quality:
  - The modelled prediction nodes that experience long-term exceedances above water quality guidelines include the downstream portions of Four Creek only, which represents an area equal to 5.7 km^2. This affected area represents approximately 3% of the LSA and 0.4% of the RSA.
  - The modelled prediction nodes that experience valuess of other parameters (Total dissolved solids and specific conductivity) greater than 10% above the 95th percentile of the baseline monitoring records include downstream Goathorn Creek (WQSEA1, WQS06, WQS05), which represents an area equal to 6.7 km^2. This affected area represents approximately 3% of the LSA and 0.5% of the RSA.
- In terms of water quantity:
  - The modelled prediction nodes that experience a change to mean annual discharge greater than 10% reduction or 30% increase include WQS21, WQS20 and WQ03DS, which encompasses an area equal to 7.6 km^2. This affected area represents approximately 3.6% of the LSA and 0.5% of the RSA.
  - A change in seasonal flow distribution greater than 10% reduction or 30% increase in any given month under average conditions is predicted to occur at WQS03, WQS21, WQS20 and

WQS03DS. This change encompasses an area equal to 11 km^2, which represents approximately 5% of the LSA and 0.8% of the RSA.

- High flows are expected to be reduced over baseline conditions for all prediction nodes which will experience a reduction in catchment area. For the segment of Four Creek which will experience a net increase in catchment area, downstream of the diversion channel, an engineering control structure will limit the discharge during extreme events, sending excess water to the East Management Pond. Similarly, the Tenas Control Pond will have the ability to control high flood events through an additional attenuation capacity up to the 1 in 10-year flood event. As a result, the increase to high flows is expected to be minimal.
- Low flows are expected to be reduced in Operations along sections of Tenas and Four creeks because of drawdown of the groundwater table around the open pit. It is expected that extreme low flows will be similarly affected.

1 Introduction

1.1 Background

Telkwa Mining Limited (TML) are proposing to develop the Tenas Coal Deposit (the Project) in northwest British Columbia. The Project is located approximately 25 km southwest of the town of Smithers within the Telkwa River watershed and will comprise of an open pit, backfill, external material stockpiles, Management Ponds, Control Ponds, a coal processing plant, and rail infrastructure area. The Tenas Project's total mine life is 25 years including Construction, Operation, Decommissioning and Reclamation phases.

SRK Consulting (Canada) Inc. have developed a water quantity and quality model based on the proposed water management designs for the Tenas Project in support of the Environmental Assessment Certificate application (EA). The EA has been prepared in accordance with the BC Environmental Assessment Office (BC EAO) Guidelines for Preparing Environmental Assessments (BC EAO 2016) and the approved Application Information Requirements document issued in 2020.

In May 2020, the EAO issued an Application Information Requirements (AIR) document that provided the requirements of the EA (EAO, May 2020). This report supports the requirements of the EA including:

- Part A, Section 1.3, Project Design and/or Alternative Means of Carrying out the Project.
- Part B, Section 3.5, Assessment Methodology and Mitigation Measures.
- Part B, Section 4.0, Environmental Effects Assessment, Surface Water Intermediate Component.
- Part E, Management Plans and Management Strategies.

The objectives of the water quantity and quality model (Water and Load Balance Model) are defined in this report, along with the model inputs, assumptions, and results. Results of the model are used to inform the EA at the regional study area level.

This report is an updated version of the Water and Load Balance Model report submitted in August 2022 as part of the Projects EA submission. Various inputs to the WLBM were also updated since 2022 and have been integrated into this revision. The following inputs and changes were made:

- Review and updates to water quality guidelines based on provincial publications, used for screening of water quality modeling results and identification of potential effects.
- Review and update the Tenas Project climatic records, based on additional data from the local station since the development of the EA baseline report (SRK 2024a).
- Review of streamflow model performance against measurements collected in 2022, along with implementation of an alternative dynamic streamflow model.
- In addition to climate records and streamflows, the climate change model has been updated to match current approved scientific requirements. All three updates are summarized in the updated hydrometric report (SRK 2024a).

- Updated background source terms incorporating seasonality (summer and winter conditions) in the model.
- Update of source terms related to barrel monitoring undertaken over the past four years which was used for quality predictions as provided in (SRK 2024b).
- Update of source terms related to the non-PAG backfill to account for methodology of constructing this dump in lifts from the bottom up and progressive reclamation through the addition of overburden and surface soil (topsoil) covers as provided in (Okane 2024).
- Review and update to the groundwater model which led to updated calculations to estimate the load in the creeks through groundwater seepage from the Project (SRK 2024c).

Details about the updates to the inputs can be found in Section 3.

1.2 Scope of Work

This report presents the inputs, methodologies, and results of the water and load balance model ("the model"). As part of this work, the following were completed:

- Develop conceptual water balance flow diagrams.
- Compile climatic and hydrologic inputs.
- Develop water balance model and evaluate effects of the Project against baseline flow conditions.
- Modify water management infrastructure as required to achieve desired objectives.
- Develop background water quality source terms and geochemical source terms for load balance model.
- Develop load balance model and evaluate effects of the Project against baseline water quality conditions.

1.3 Model Objectives

Geochemical characterization studies have shown that a portion of waste rock from mining activities is expected to be potentially acid generating (PAG) material. To minimize oxidation of this material and the generation acid drainage and/or metal leaching, PAG rock will be stored in Management Ponds to maintain a perpetual water cover. One of the primary functions of the model is to test the ability of the Project water management infrastructure to maintain water cover.

The objectives of the model and water management plans include:

- Ensuring a minimum of 0.5 m water cover is maintained in Management Ponds within 6-months of PAG rock placement and a minimum 1.5 m throughout the rest of life of mine and Post-closure.
- Ensuring sufficient water is available to meet coal preparation plant (CPP) demand throughout Operations.
- Estimating the quality and quantity of water to be discharged to the receiving environment.

- Estimating the quality and quantity of water in the receiving environments at discharge locations and at prediction nodes in the receiving environment.
- Providing a basis for determining water management infrastructure requirements and water treatment requirements (if any).
- Providing a basis for the estimation of water management costs and water treatment costs (if any).

2 Model Overview

2.1 Regulatory Requirements and Commitments

Water takings for the Project are expected to be subject to the provincial *Water Sustainability Act* via a license for the use of surface and/or groundwater. The Project is expected to be subject to the federal *Fisheries Ac*t via the future *Coal Mining Effluent Regulations* which are currently in development (ECCC 2018), as well as the provincial *Environmental Management Act* via a Waste Discharge Authorization permit.

The *Coal Mining Effluent Regulations* are expected to specify end of pipe limits for total suspended solids (TSS), nitrate, and selenium for new and existing coal mines.

In the BC provincial jurisdiction, end of pipe limits for discharge of excess water to the environment may be specified in an Effluent Discharge Permit (EDP) issued by the BC Ministry of Environment (BC MOE) under the provincial *Environmental Management Act,* in addition to established surface water quality guidelines (WQG) for receiving environments. In advance of an EDP, the long-term average BC Approved Water Quality Guidelines or BC AWQG (ENV 2025a) and the BC Working Water Quality Guidelines or BC WWQG (ENV 2025b) for freshwater aquatic life were applied for the evaluation of results from the load balance. Canadian Council of Ministers of the Environment (CCME) Water Quality Guidelines for the Protection of Aquatic Life (CCME WQG) are applied for parameters for which there is no BC AWQG or BC WWQG.

The WQG incorporated for the Project are summarized in Section 3.9.

2.2 Model Description

2.2.1 Simulation Approach

The model uses a daily time step, and reports results as monthly averages throughout the life of mine through the year 2100. The year 2100 was selected based on the current extent of available global circulation models for climate change evaluation.

Water quantity results were generated using two sets of hydrologic conditions, both of which account for climate change:

- Historical hydrologic conditions based on select years from the historical record including a composite year with monthly historical records corresponding to monthly average conditions and resulting in similar annual precipitation to the mean annual precipitation, a 1 in 100-year dry and a 1 in 10-year wet historical year. Details on this methodology are described in Section 3.1.1. Climate change adjustment factors were applied to temperature and precipitation inputs (Section 3.1.5).
- Monte Carlo simulation using a weather generating (WGEN) software with climatic data, including daily precipitation and daily temperature, for the Project area. A total of 100 model runs were completed using this approach. Climate change adjustment factors were applied to the daily generated temperature and precipitation values. At the end of 100 model runs, all results were

compiled, and probability distributions of the results were generated (i.e., 5th, 50th and 95th percentiles). Details of this methodology are described in Section 3.1.2.

Water quality predictions were completed using deterministic model runs (i.e., a single run with no probabilistic elements for climatic variables) with average hydrologic conditions to be consistent with the derivation of source terms.

2.2.2 Governing Equations

The water and load balance model operates based on conservation of mass. The water balance component tracks all inputs, outflows, and available storage at the Project. The water balance can be represented in a simplistic form as follows:

$$Water\ Storage = Water\ Input - Water\ Output \quad \text{(Eq. 2.1)}$$

Where the total water inputs include groundwater and precipitation, and water outputs include groundwater, evaporation, process water demand, discharge offsite and water loss to rock void space. Storage is available in various Project facilities.

The load balance for the Project was developed to evaluate loadings from Project components to the receiving environment. The load balance and resultant receiving water quality predictions were used as a tool to iteratively refine water management infrastructure for the Project throughout the life of mine.

The load balance assumes fully mixed conditions at each prediction node and time step. The mass balance does not account for some physical, chemical, and/or biological processes such as aerobic and anaerobic degradation, sorption and desorption, oxidation and reduction, dissolution and precipitation, and incomplete mixing within receiving environments.

Loadings and concentrations were calculated for each Project component, and loadings were generated for each corresponding receiving environment node in the water balance. Two types of loadings included in the load balance:

- Direct loadings based on defined input source terms.
- Linked loadings from reservoirs (from one reservoir to another).

Direct loadings are calculated based on the concentrations of source terms (eq. 2.2).

$$Direct\ Loading\ [mg] = Inflow\ Volume[m^3] \times Source\ Term\ Concentration\left[\frac{mg}{L}\right] \times 1000\ L/m^3 \quad \text{(eq. 2.2)}$$

Linked loadings (eq. 2.3) from reservoirs are calculated based on the calculated concentration (eq. 2.4) for the reservoir and associated inflow from the water balance.

$$Linked\ Loading\ [mg] = Inflow[m^3] \times Concentration[\frac{mg}{L}] \times 1000\ L/m^3 \quad \text{(eq. 2.3)}$$

$$Concentration = \frac{Mass\ (mg)}{Volume\ (L)} \quad \text{(eq. 2.4)}$$

2.3 Project Overview

The Project is located approximately 25 km southwest of the town of Smithers and is in the Telkwa River watershed, amongst the smaller watersheds of Tenas, Four, and Goathorn creeks (Figure 2-1). Workings will consist of an open pit, generation of both PAG and non-PAG rock as well as overburden material, Management Ponds, sedimentation ponds, a Coal Processing Plant (CPP), and rail infrastructure. The Project's total mine life is approximately 25 years including the Construction, Operation, Decommissioning and Reclamation phases. The Post-closure phase will occur after the decommissioning and reclamation phase are completed and will have an unspecified timing but will likely be approximately 50 years.

Downstream water users include fish populations in Four, Tenas and Goathorn creeks as well as Telkwa and Bulkley Rivers. The Village of Telkwa is located downstream at the confluence of the Telkwa and Bulkley Rivers, and further downstream on Bulkley River is the Town of Smithers following by Witset.

2.3.1 Project Infrastructure

Project infrastructure incorporated into the model is described below. Figure 2-1 presents the Project infrastructure footprint at the end of the life-of-mine.

Sedimentation Ponds

Sedimentation ponds provide residence time for sediment removal and water storage. Ten ponds will be included at the Project, including the Tenas Control Pond, the Coal Processing Plant (CPP) Sedimentation Pond, the Rail Infrastructure Sedimentation Pond, the Explosives Facility and Explosives Magazine East and West Tenas Access Corridor, Gravel Quarry 1 and 2, and Rock Quarry Sedimentation Ponds. Due to their small footprints (less than 0.01 km^2), disconnectedness from the main mining water management system, primarily TSS as the only POC, and timing, the Explosives Facility, Explosives Magazine, East and West Tenas Access Corridor, Gravel Quarry 1 and 2, and Rock Quarry Sedimentation Ponds Sedimentation Ponds were not included in the water and load balance model.

The Tenas Control Pond will be constructed downstream of all mining infrastructure and will also serve as the secondary water supply source to the CPP[1] as well as providing water supply to the Management Ponds. Excess water will be pumped from Tenas Control Pond to a tributary of Goathorn Creek, which will include a minimum discharge rate during open water months (May until October) to mix with treated sewage effluent.

The CPP Sedimentation Pond and Rail Infrastructure Sedimentation Pond are local facilities at the CPP area and rail infrastructure area, respectively. Inflows to these ponds will include drainage from associated infrastructure, and outflows will consist of evaporation and discharges to downstream creeks and rivers via pumping systems and emergency spillways.

Management Ponds

The Project will include three Management Ponds for subaqueous storage of PAG rock and processed rock: North Management Pond (NMP), East Management Pond (EMP) and West Management Pond (WMP). All Management Ponds will be lined to reduce seepage losses to the environment. Upon completion of PAG rock placement within each facility, a non-PAG rock cover will be placed across the top of PAG, followed by a layer of overburden to reduce evaporation losses.

The NMP ring-dyke dam will be constructed during pre-mining at the downstream extent of the open pit and will store PAG rock during the first years of mining. Due to its geometry, all inflows other than direct precipitation will be pumped into the NMP, including water from Tenas Control Pond, subsequent Management Ponds, and inflows from the open pit. Outflows include groundwater seepage and evaporation, overflow via gravity spillway to the Tenas Control Pond, and pumped flow to the subsequent Management Ponds.

[1] Primary water supply source to the CPP is the open pit sump.

The EMP will consist of a dam along the northern extents of the facility, upstream of the NMP. PAG rock placement in the EMP will begin once the NMP is full. A division dam will also be constructed to separate between the subsequent WMP. Inflows will include natural upstream runoff, direct precipitation, and pumped flows from Tenas Control Pond, NMP and the open pit. Outflows include groundwater seepage and evaporation, and discharge via pump or spillway to the NMP and EMP.

The WMP will consist of a dam along the northern and western extents of the facility, adjacent to the EMP dam and directly upstream of the NMP. WMP will consist of a storage area on natural ground as well as a portion of the open pit, referred to herein as the In-Pit WMP and Ex-Pit WMP. Like the EMP, inflows to the WMP will include natural upstream runoff, direct precipitation and pumped flows from the other Management Ponds and the open pit. At closure, the backfilled open pit will discharge via gravity through a rock drain directly into the WMP. Outflows include groundwater seepage and evaporation, and discharge via pump or spillway to the NMP and EMP.

Open Pit

A single open pit will be mined throughout Operations and will be backfilled with Non-PAG rock. The open pit is dewatered via pumping from a sump to the active Management Pond[2] during active mining.

Non-PAG rock is backfilled into the open pit throughout Operations. At closure, Non-PAG rock is covered with overburden and active dewatering will cease, allowing the remaining areas to flood and form the End Pit Lake. Discharge at closure will occur through the Non-PAG rock towards the WMP.

Coal Processing

Coal processing will occur on-site at the CPP. The CPP will produce coal that will be transported to the Rail Infrastructure Area for transport off-site, as well as processed rock which will be deposited in Management Ponds with PAG rock.

2.3.2 Project Stages

Four Project stages are described in Table 2-1.

[2] A Management Pond is considered active when PAG is being placed in it.

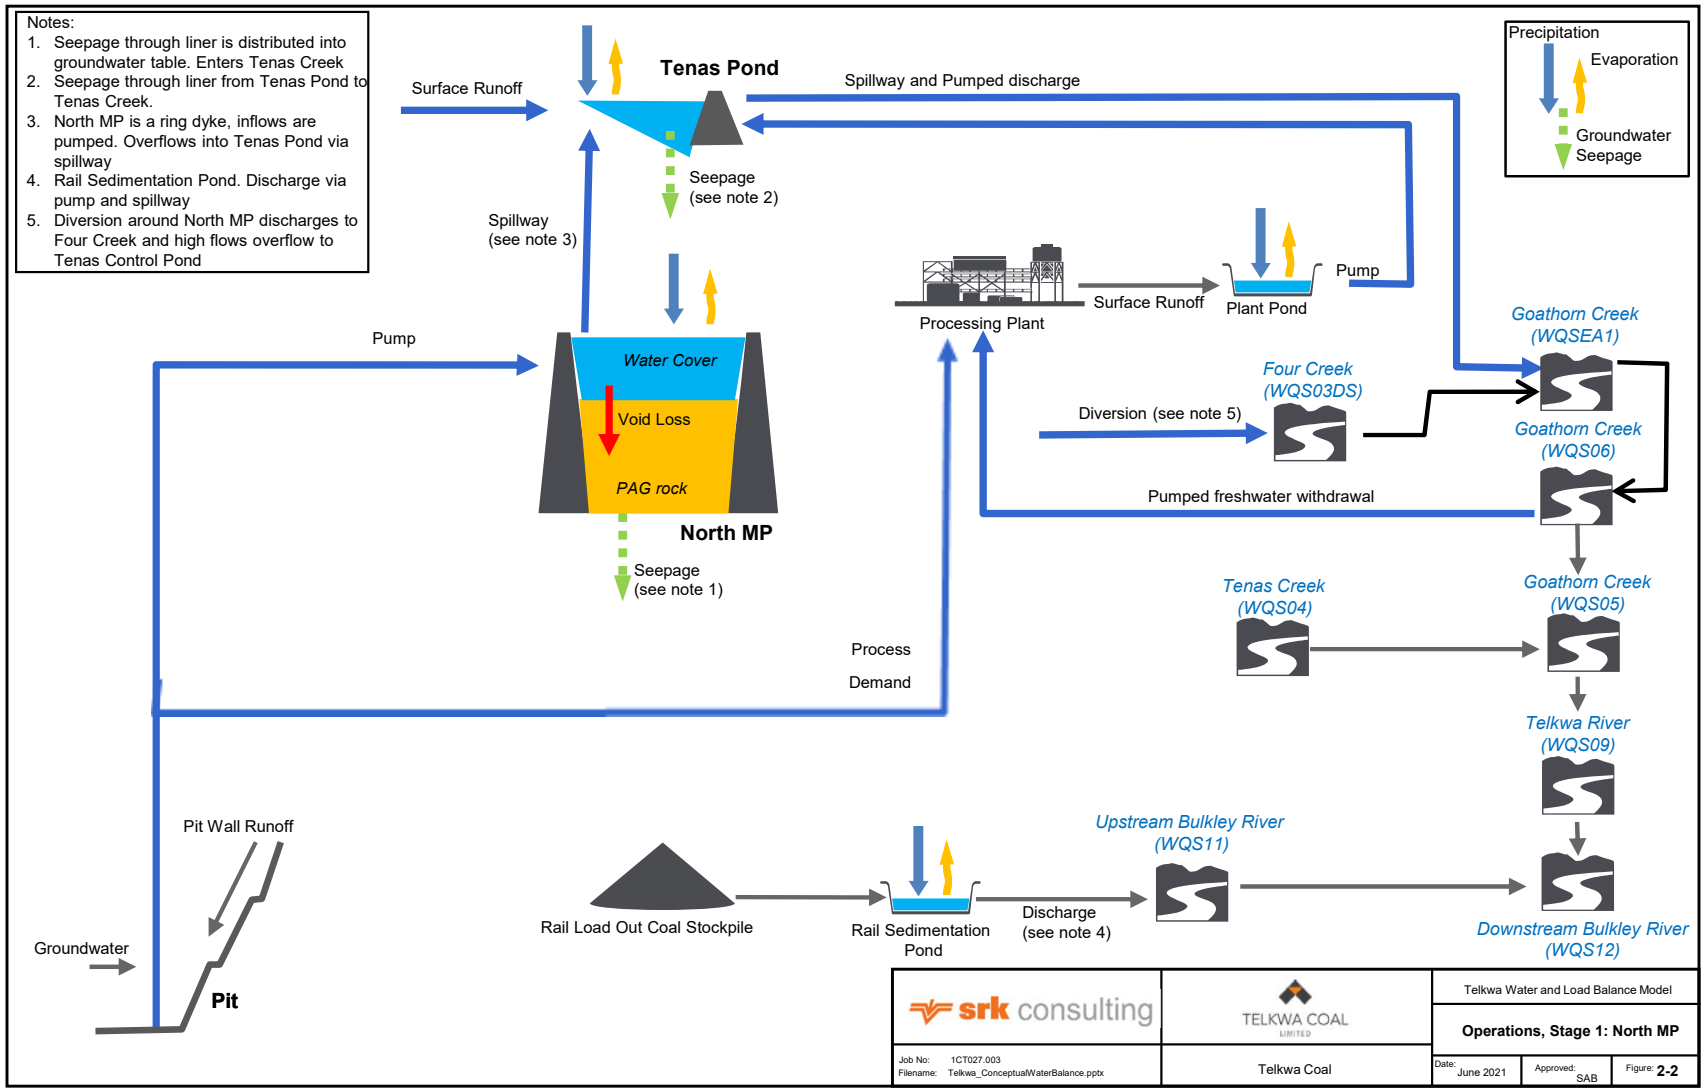

Table 2-1: Project Phases

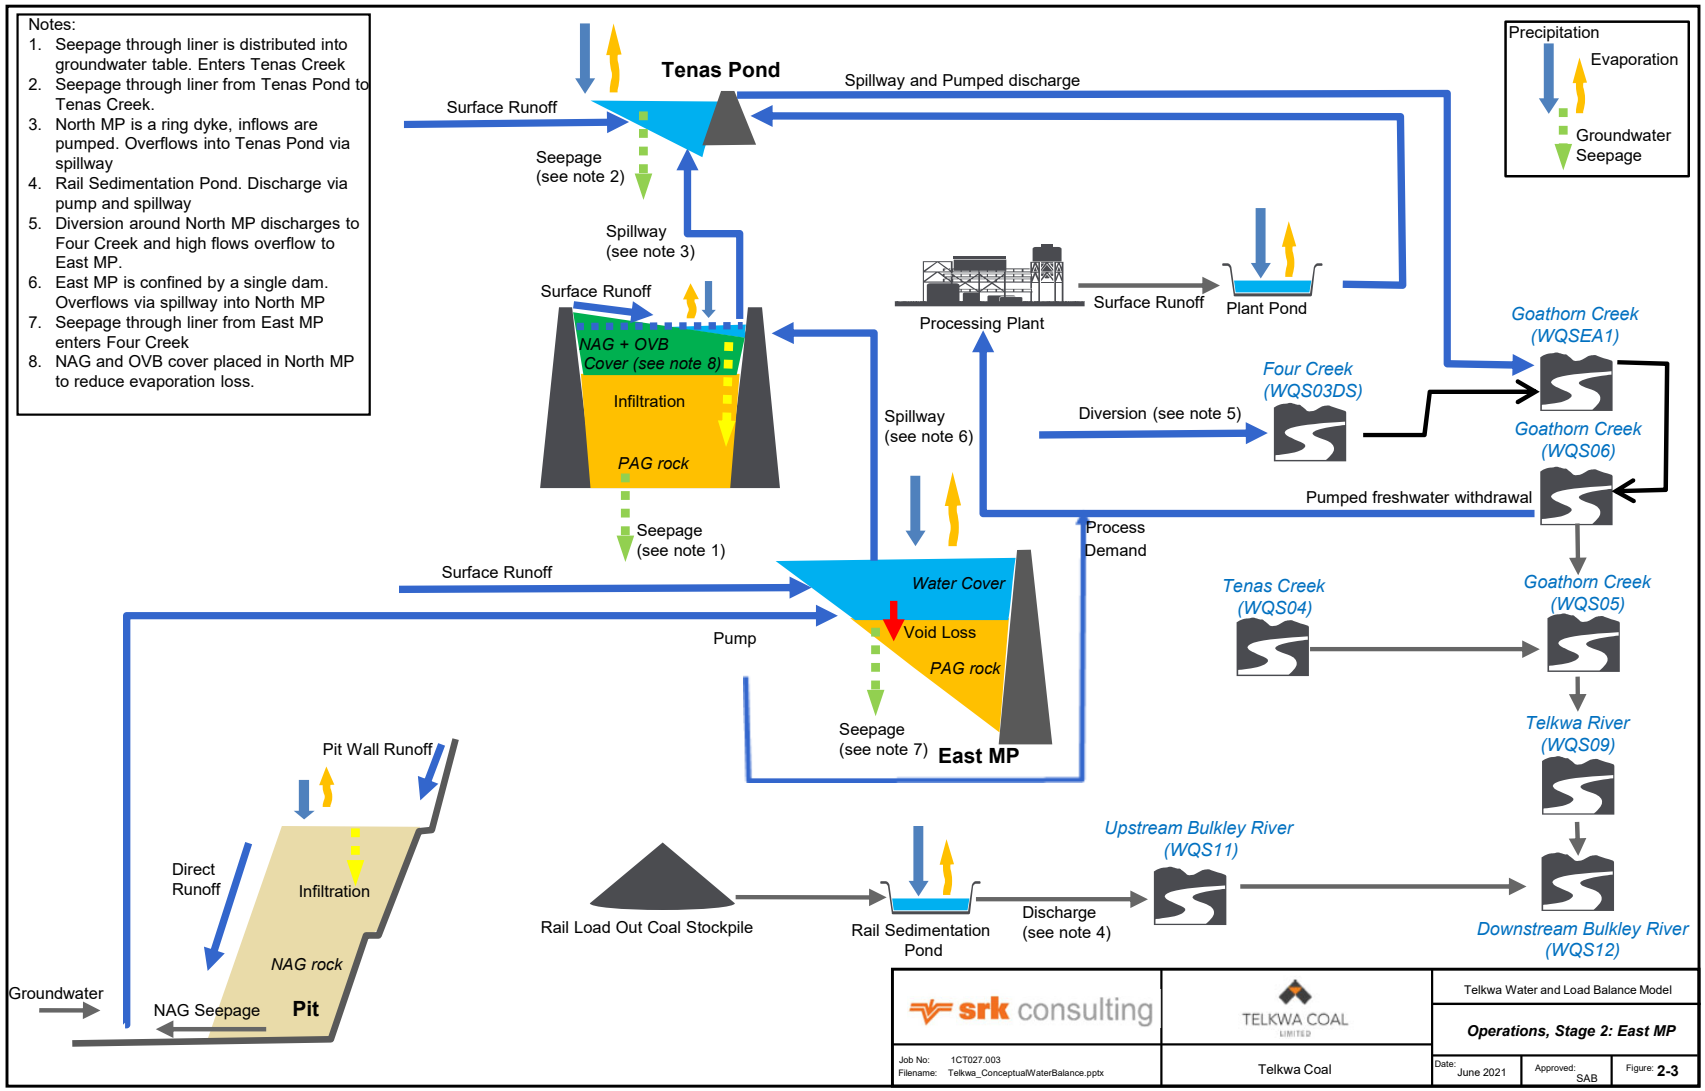
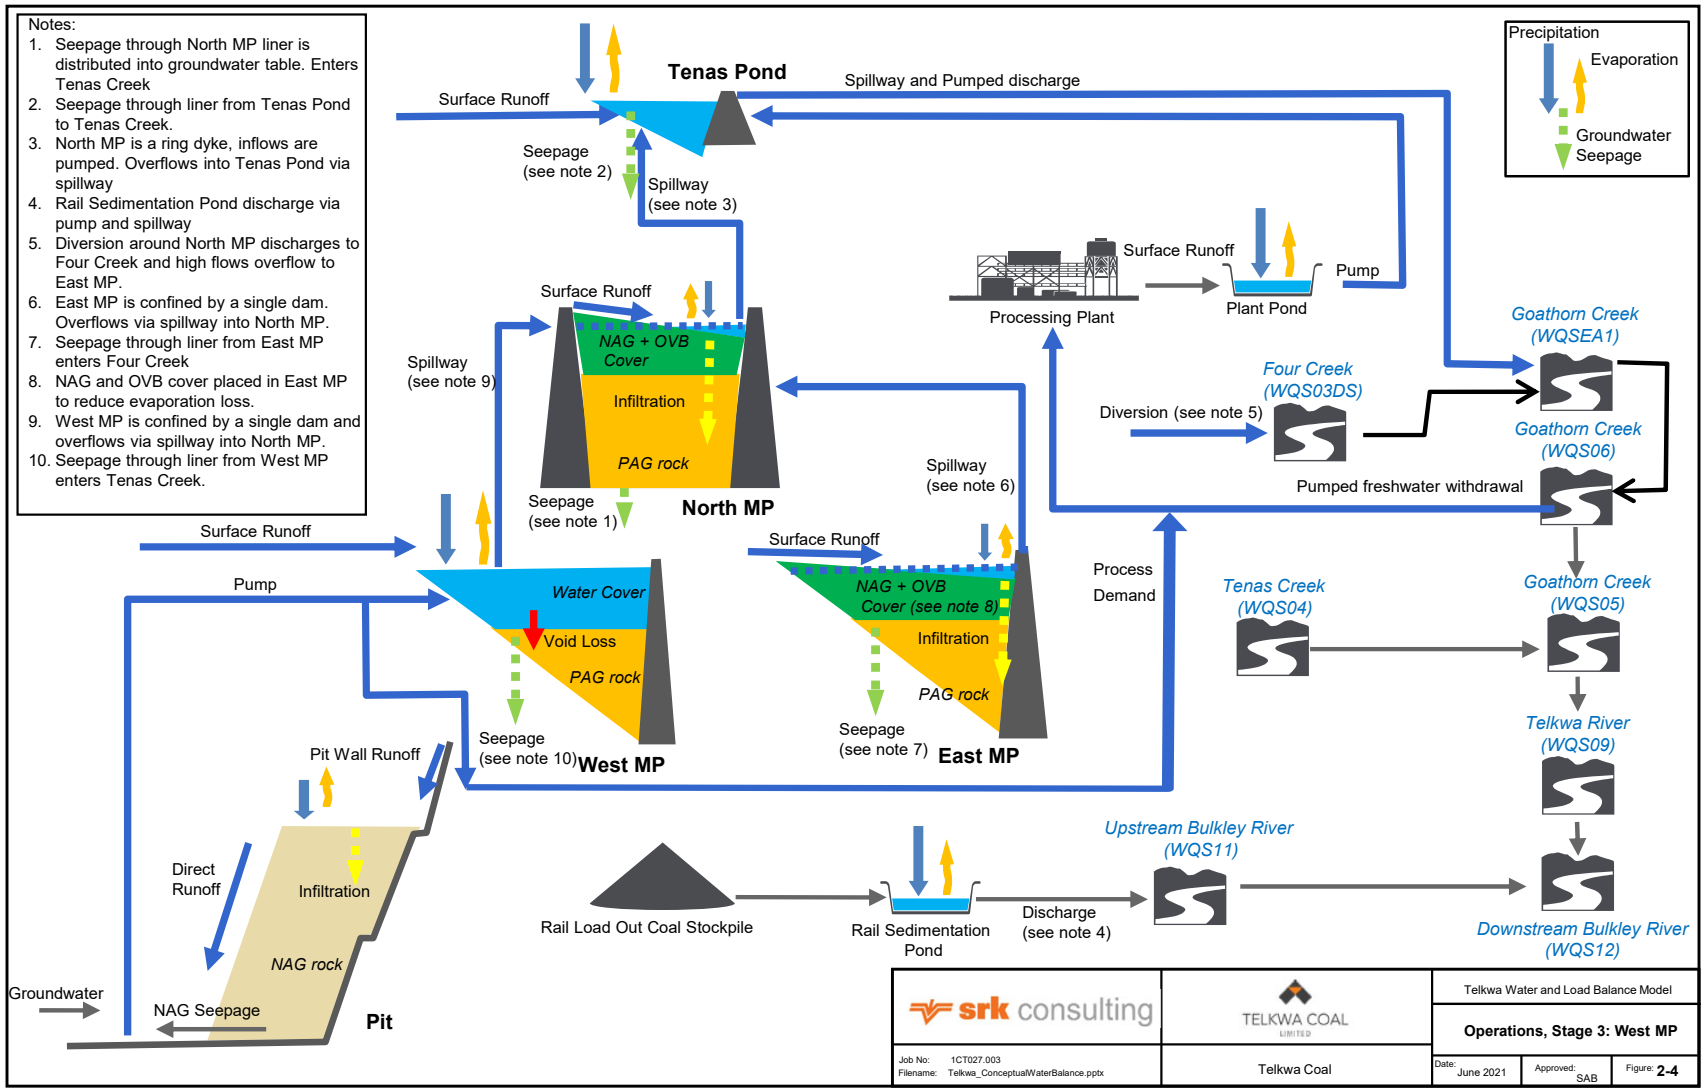
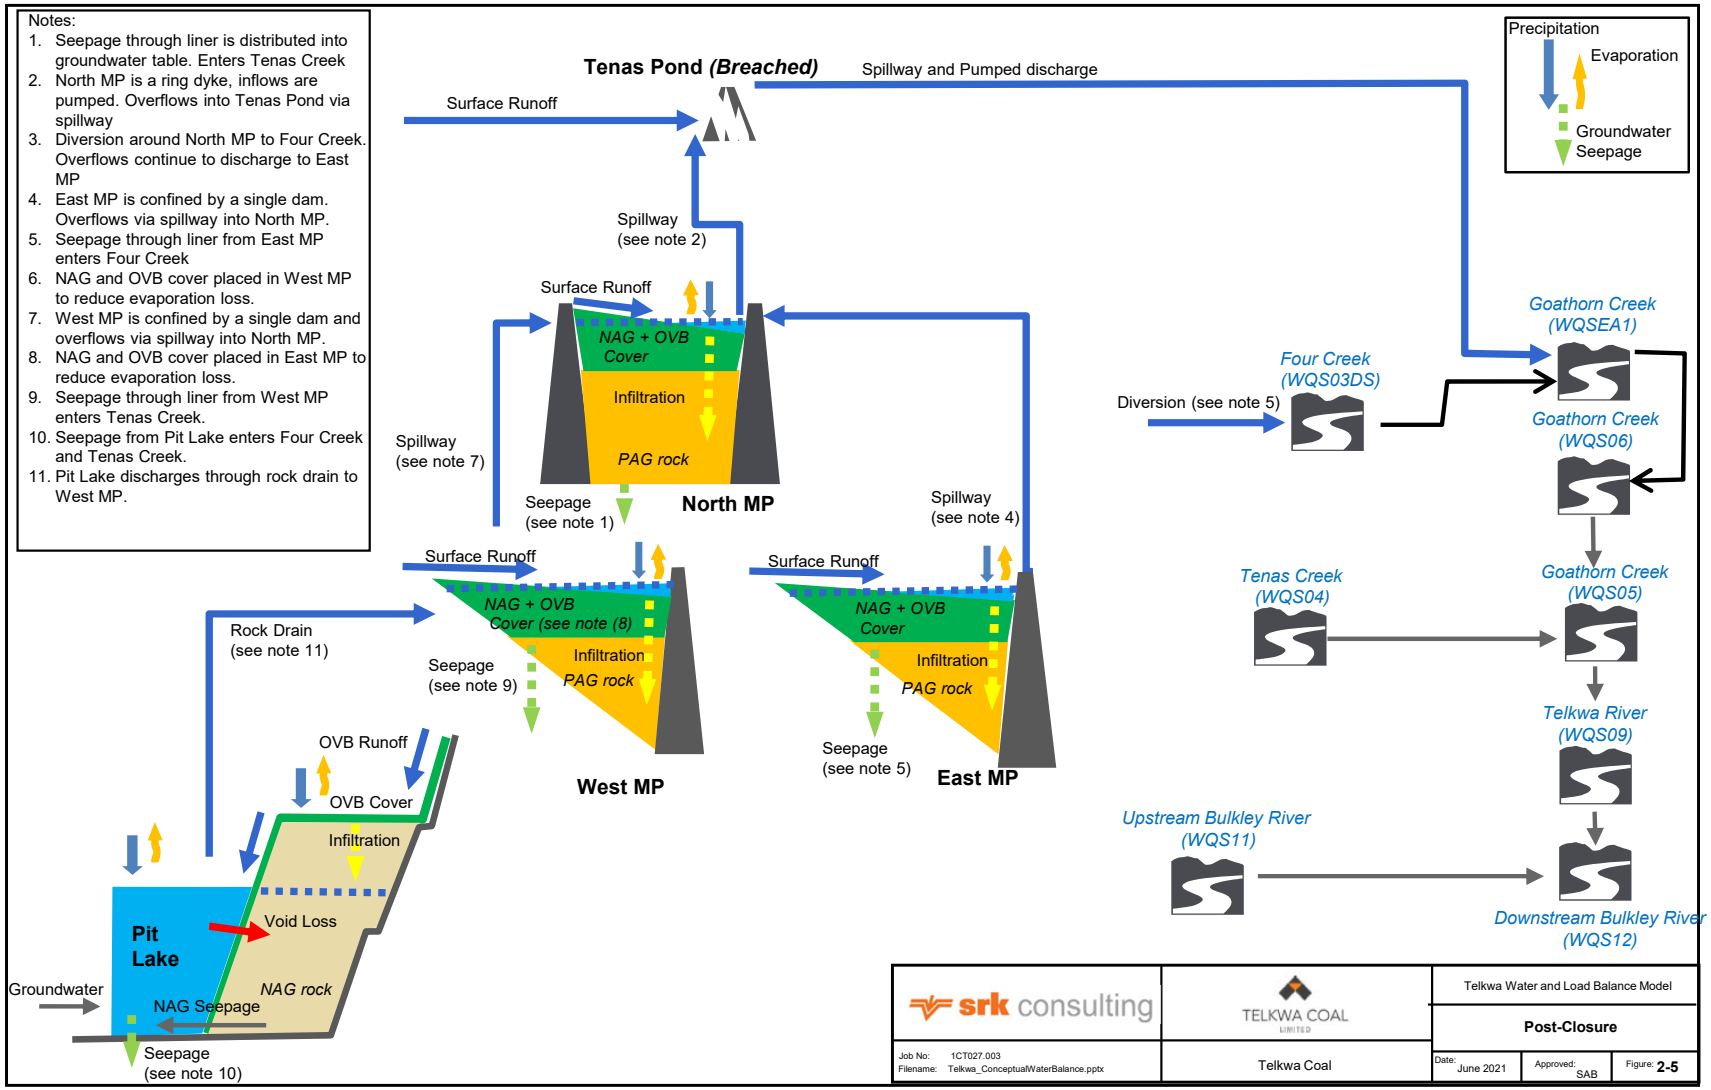


Project Stage	Project Years	Modelled Calendar Year	Length of Phase (years)	Description of Activities
Construction	-0.5 to 0	2020	1.5	Site clearing, soil salvage, open pit development, building construction, service and haul road development, Rail Infrastructure construction, bridge construction and development of onsite utilities and services. Development of mine rock, and overburden storage piles, stockpiling of reclamation material such as soil, overburden, and other materials suitable for reclamation. Development of water management systems and management ponds for storage of potentially acid generating (PAG) materials.
Operation	1 to 21	2022	21	Development of the open pit through drilling, blasting, loading, and hauling functions. Development of mine rock, and overburden storage piles, stockpiling of reclamation material such as soil, overburden, and other materials suitable for reclamation. Development of water management systems and management ponds for PAG storage. Conducting coal processing, stockpiling of raw coal prior to processing, and stockpiling of processed coal prior to shipping. Progressive reclamation will be accomplished during operation including, where available, reclamation activities such as sloping, topsoil placement and revegetation.
Decommissioning and Reclamation	22 to 25	2043	4	Decommissioning of infrastructure onsite plus reclamation activities, including sloping of storage piles, backfill materials, and placement of reclamation materials including growth media, overburden and non-PAG rock for management pond covers and revegetating surfaces that are planned to be reclaimed.
Post-closure	26 to 50	2047	53	Approximately 10 years of Active Post-Closure. This involves the filling of the open pit with water, monitoring of vegetation growth and water quality for both groundwater and surface water and wildlife. Control and sedimentation ponds may still be needed for settling of total suspended solid levels. The management ponds are left as dry land reclamation except for portions that will be left as open water. Passive closure when the control and sedimentation ponds are no longer required for settling of total suspended solid (TSS) levels and the management ponds are covered and reclaimed except for portions left as open water. Telkwa Coal Limited (TCL) will monito site



Note: Modelled Calendar year have been used historically, starting in 2020. Future modelling revisions will likely update these dates to reflect actual start date of mining.



2.3.3 Flow Diagrams

The water balance conceptual flow diagrams are provided in Figure 2-2, Figure 2-3 and Figure 2-4 for Operations with the NMP, EMP and WMP, respectively, as well as in Figure 2-5 for Post-closure.

2.4 Overview of Predictions

2.4.1 Prediction Nodes

Model prediction nodes were selected to characterize upstream and downstream conditions in relation to the Project and its discharges. Creeks and rivers which were identified as providing habitat to fish and aquatic life have multiple prediction nodes. Node locations were typically located at historic water quality monitoring sites, with several additional prediction nodes beyond the water quality campaigns on Four Creek and Tenas Creek.

Table 2-2 summarizes the prediction nodes in terms of their geographic location and the stream in which they are located. Justification for node selection is also presented, based on coordination with other EA value component disciplines and review of potential effects from the Project. Node locations are also presented on Figure 2-6 with the final footprints of the Project. Of note, the prediction node WQSEA1 was added after the first version of this report based on feedback during the EA review process.

Table 2-2: In-Stream Prediction Nodes

Prediction Node	Receiving Environment	Justification for Node Selection	Coordinates NAD 1983 UTM Zone 9N

2.4.2 Modelled Assessment Cases

Multiple assessment cases were developed to understand the range of potential effects from the Project throughout the life of mine. Cases incorporate variability in hydrologic conditions, groundwater conditions and geochemical source terms:

- **Background concentrations**: Concentration (in mg/L of water) of each water quality parameter applied to streamflow or groundwater generated from natural catchments. All assessment cases consider the median (50th percentile) water quality data. The upper percentile (95th) is used for screening purposes of model results.
- **Geochemical source terms**: Concentration (in mg/L of water from a given source) or loading rate (in mg per kg of mine rock placed over time) source terms were developed from review of geochemical datasets. Results are presented for the base case source term, which is most likely to occur, and a high source term for a reasonable worst case.
- **Hydrology:** Streamflow and Project discharge are driven by precipitation and temperature inputs and calibrated runoff parameters. Hydrologic scenarios are further described in Section 3.1. and include:
  - Repeated average year precipitation and temperature,
  - Consecutive wet or dry year precipitation,
  - Stochastically generated daily precipitation, and
  - A low flow condition using the 7-day low flow in a 1 in 10-year return period (7Q10).
- **Groundwater seepage**: Groundwater modeling results were incorporated into the model (Section 0). Two cases are presented, including the expected groundwater conditions and sensitivity case seepage (high hydraulic conductivity) rates.

A Pre-Mining Case was simulated in parallel to each assessment case to evaluate the effects of the Project for surface water quantity with respect to a similar baseline. The hydrologic scenario applied to each assessment case was mirrored in the Pre-Mining Case for the same years, enabling comparisons with identical assumptions without mining influences. The assessment considers effects in relation to surface water quantity based on the percent change over Pre-Mining Case (i.e., without effects of mining) conditions.

Table 2-3 presents a summary of assessment cases applied in the model. Relevant results include water quantity and water quality in the receiving environment (Stream) as well as within Project infrastructure (Project).

Table 2-3: Summary of Modelled Assessment Cases

Assessment Case	Background Concentrations	Geochemical Source Terms	Hydrology	Groundwater Seepage	Relevant Results	Purpose
Project Case	Median from Baseline	Typical	Average Annual Precipitation	Expected Groundwater Conditions	Stream and Project Water Quantity, Water Quality	Applied and evaluated for all prediction nodes, forming the basis of the effects assessment of the Project
Alternative Case 1	Median from Baseline	Typical	Average Annual Precipitation	Increased hydraulic conductivity Groundwater Conditions	Stream and Project Water Quantity, Water Quality	Considers higher seepage rates from Project infrastructure and higher drawdown from open pit and the effects on Four Creek and Tenas Creek baseflow rates and winter (low flow) water quality
Alternative Case 2	Median from Baseline	High	Average Annual Precipitation	Expected Groundwater Conditions	Stream and Project Water Quality	Considers higher loading rates from Project to downstream environment and the associated in-stream water quality. Used for Initial Dilution Zone model scenarios in Goathorn Creek (SRK 2025b)
Alternative Case 3	n.a.	n.a.	Consecutive 100-year Dry Events	Expected Groundwater Conditions	Project Water Quantity	Minimize water available for water covers
Alternative Case 4	Median from Baseline	Typical	Consecutive 10-year Wet Events	Expected Groundwater Conditions	Stream and Project Water Quantity, Water Quality	Maximize Project discharge rates and the effects to receiving environment (Goathorn Creek) in terms of flow rates and water quality

Assessment Case	Background Concentrations	Geochemical Source Terms	Hydrology	Groundwater Seepage	Relevant Results	Purpose
Alternative Case 5	Median from Baseline	Typical	7Q10 Low Flow with Average Annual Precipitation[1]	Expected Groundwater Conditions	Stream Water Quantity, Water Quality	Project influence on low flow conditions. Water quality predictions used in Initial Dilution Zone model (SRK 2025c)
Alternative Case 6	n.a.	n.a.	Stochastic Precipitation	Expected Groundwater Conditions	Project Water Quantity	Effect on water covers and Project discharge rates
Alternative Case 7	Median from Baseline	Typical	10% increased Annual precipitation	Expected Groundwater Conditions	Stream and Project Water Quantity, Water Quality	Effect on Project discharge rates and water quality in receiving environment
Pre-Mining Case	n.a.	n.a.	Variable to coincide with selected assessment case	Pre-Mining	Stream Water Quantity	Baseline conditions without Project interaction (i.e., no-mining condition)

n.a. = not applicable

2.4.3 Spatial Boundaries of Assessment

Two spatial boundaries were considered in the EA for surface water:

- the Local Study Area (LSA).
- the Regional Study Area (RSA).

The LSA is defined where direct discharges occur to watercourses within the vicinity of the mine (e.g., Tenas Creek, Four Creek, and Goathorn Creek), to the edge of the mixing zone in the Telkwa River, and downstream of the Rail Infrastructure Area in the Bulkley River. The total area of the LSA is 208.3 km^2.

The RSA, which encompasses the LSA, extends to monitoring location WQS12 in the Bulkley River, approximately 2km downstream of the confluence with the Telkwa River, and includes the Telkwa River catchment area to be consistent with other valued component boundaries. The RSA continues upstream of the confluence of the Telkwa River to the Bulkley River at Quick Water Survey of Canada station (08EE004), which captures conditions upstream of the Rail infrastructure Area. The total area of the RSA is 1430 km^2.

Spatial boundaries are presented in Figure 2-7, where the LSA is a purple dashed line, and the RSA is a green dashed line.

2.4.4 Predicted Parameters

The following types of model results are presented for water quality and water quantity to support the EA Application.

Water Quantity Results

Internal Project Results:

- Ability of the Project to maintain the minimum water cover requirements for all Management Ponds throughout life of mine.
- Ability of the Project to meet process water demands at the CPP.
- Project discharge rates to Goathorn Creek tributary.

Receiving Environment Results:

- Relative change to streamflow under a no-mining condition (Pre-Mining Case). Monthly percent change over Pre-Mining conditions were calculated at each node and summarized per Project stage.

Water Quality Results

Parameters included in the model are summarized in Table 2-4. Other parameters estimated outside of the model include temperature, pH, conductivity, total suspended solids, total dissolved solids, PAHs, and turbidity. Estimates for these parameters were developed based on relationships to modelled parameters, or qualitatively.

Internal Project Results:

- Monthly average and maximum concentrations within Management Ponds as well as all discharging facilities, including the Tenas Control Pond and the Rail Infrastructure Sedimentation Pond. Note that due to their small footprints (less than 0.01 km^2), disconnectedness from the main mining water management system, primarily TSS as the only POC, and timing, the Explosives Facility, Explosives Magazine, East and West Tenas Access Corridor, Gravel Quarry 1 and 2, and Rock Quarry Sedimentation Ponds Sedimentation Ponds were not included in the Goldsim water and load balance model but will discharge runoff to the downstream environment. Changes to water quality downstream of these ponds is expected to be minimal based on use of best management practices. Total suspended solids will be controlled with sedimentation pond designs.
- Results are screened against the WQG as outlined in Section 2.1, as well as against baseline conditions.

Receiving Environment Results:

- Monthly average water quality results at each prediction node, screened against the WQG.
- For each period and each Project stage, both the average and maximum monthly results are presented for winter and summer conditions:
  - Winter extends from November through April (frozen conditions)

– Summer extends from May through October (open-water season).

Table 2-4: Water Quality Parameters Modelled in the Load Balance

Boron, total	Iron, dissolved	Molybdenum, total	Sodium, dissolved	Zinc, total

2.4.5 In-Stream Characteristics

Changes from the Project on streamflow are characterized in accordance with guidance documents for the EA Application. Surface water has been identified as a valued component, of which water quantity and water quality are each sub-components. The characterization of effects (magnitude, frequency, duration, context, reversibility, and extent) is discussed in the EA Application.

Surface water quantity results are evaluated in terms of:

- Change to mean annual discharge, based on percent change between mean annual discharge in Project Case conditions and Pre-Mining conditions.
- Change to seasonal flow distribution, based on percent change between monthly average discharge in Project Case conditions and Pre-Mining conditions.
- Change to low flows, based on percent change between the 7Q10 in Alternative Assessment Case 5 and Pre-Mining conditions.

Surface water quality results are evaluated in relation to WQG, in context with the natural variability from baseline monitoring data.

3 Model Inputs and Assumptions

3.1 Climate and Hydrology

SRK prepared a hydrometeorological characterization report for the Project to support water management designs and water balance modeling (SRK 2024a). Outputs from the analyses relevant to the water balance include:

- Average lake evaporation rates.
- Long-term temperature and precipitation records developed from Smithers Airport and other regional datasets and corrected for the Project location and prediction node catchments.
- Rainfall-runoff models calibrated for each stream.

Inputs to the water balance are summarized in the following sections.

3.1.1 Historical Climate Conditions

The Project-specific precipitation record includes 77 years of data, from 1943 to 2022. Annual precipitation values were compared with the annual frequency analysis results presented in the hydrometeorological characterization report (SRK 2024a), and select years were identified to simulate dry and wet conditions. Average conditions were represented by a composite year made from average monthly precipitation from the synthetic record. Table 3-1 presents the historical precipitation datasets incorporated into the model for select hydrologic conditions, including the 100-year dry and 10-year wet.

Table 3-1: Historical Precipitation Data Incorporated for specific Hydrologic Conditions in the Model

Hydrologic Condition	Return Period (years)[1]	Frequency Analysis Results for Annual Precipitation (mm/a) [2]	Corresponding Historical Year with Similar Annual Precipitation	Historical Annual Precipitation (mm/a)
Wet	10	798	1957	799
Mean	n.a.	676	Composite	666
Dry	100	454	1970	467

Source:https://srk.sharepoint.com/sites/NACAPR002055/Internal/200_Review%20New%20Climate%20and%20Streamflow%20Data/Met_Data/TenasStation_Review%20of%20Average%20Year_202403_njs.xlsx?web=1

Notes:

1. Frequency analysis described in SRK 2024a.
2. Return periods were selected based on available historical information.

The precipitation inputs used to simulate mean hydrologic conditions were updated. Instead of selecting a year from the historical record which matched the mean annual precipitation, a synthetic year was generated, with monthly precipitation sums that matched the monthly average precipitation distribution, as well as the mean annual precipitation. This provided a better approximation of monthly

average conditions and is run as the base condition climate to simulate the historical mean hydrologic conditions.

Sensitivity analyses (Section 2.4.2) were prepared to assess three consecutive wet or dry years applied at critical periods throughout the life of mine:

- Three consecutive dry years were applied at the most critical period for water demand, during operation of all three Management Ponds. The Project discharge during this period is minimized, which influences downgradient streamflow.
- Three consecutive wet years were applied at the most critical period of the mine life, at the end of Operations when the Project footprint is maximized and the Management Ponds approach their maximum capacity. This period produced the highest annual discharge rates and therefore increases stream water quantity and impacts stream water quality.

Under all historical precipitation conditions, the historical temperature record coinciding with precipitation inputs was used.

3.1.2 WGEN and Stochastic Hydrology

The weather-generating (WGEN) model stochastically generates daily precipitation and minimum and maximum air temperature based on monthly statistics. WGEN generates precipitation independently of other variables and air temperature is dependent on the occurrence of rain. The long-term timeseries for air temperature and total precipitation developed for the Project were used as inputs to generate statistical parameters for the WGEN model.

Precipitation is first determined by the probability of consecutive precipitation days, then the precipitation amount is generated according to a gamma distribution. The monthly probabilities of a wet day occurring after a wet day, *P(W/W)*, or dry day, *P(W/D)*, are given in Table 3-2. A wet day is defined as having more than 0.25 mm of precipitation. Table 3-3 shows the fitted gamma distribution parameters (α and β). The WGEN methodology is described in (Richardson and Wright, 1984).

Table 3-2: Probabilities of Wet or Dry Day Occurrence

Month	P(W/W)	P(W/D)

Source: https://srk.sharepoint.com/sites/NACAPR002055/Internal/ Water Balance Modelling/Mode/Updated EA Case/TelkwaEAModel_v41.gsm

Air temperature is generated based on the occurrence of precipitation, and the seasonal change in the means and coefficients of variation for minimum and maximum air temperature fitted with a sinusoidal curve:

$$u_i = \bar{u} + C\cos\left(\frac{2\pi}{365}(i - 200)\right), i = 1, \ldots, 365$$

Where u_i is the air temperature or coefficient of variation value on day *I,* $\bar{u}$ is the mean of u_i, *C* is the seasonal amplitude, and *i* is the amplitude position in days. Richardson and Wright (1984) recommends a *i* of 200 days. The maximum daily air temperature is highly dependent on the occurrence of precipitation; however, the minimum daily air temperature is not, and statistics were generated using both wet and dry days. These parameters are presented in Table 3-4, where temperature is presented in units of Kelvin.

Table 3-4: WGEN Air /temperature Parameters

Parameter	Value
Mean of maximum air temperature (dry) (K)	281
Mean of maximum air temperature (wet) (K)	279.8
Amplitude of maximum air temperature (wet or dry) (K)	13.6
Mean coefficient of variation of maximum air temperature (wet or dry)	0.0184
Amplitude of coefficient of variation of maximum air temperature (wet or dry)	-0.00529

Parameter	Value
Mean of minimum air temperature (wet or dry) (K)	269.9
Amplitude of minimum air temperature (wet or dry) (K)	9.763
Mean coefficient of variation of minimum air temperature (wet or dry)	0.0188
Amplitude of coefficient of variation of minimum air temperature (wet or dry)	-0.0.0112

3.1.3 Prediction Node Climate Adjustments

Based on the range of terrain and elevation bands within the watersheds of each prediction node, an adjustment to climate parameters was required to develop streamflow estimates in each stream. Detailed methodology for the climate adjustments is presented in Appendix A.

The long-term Project temperature and precipitation records were adjusted using the Parameter-elevation Relationships on Independent Slopes Model (PRISM) to estimate climate parameters for each of the local hydrometric stations within each stream. An average monthly precipitation for each hydrometric station watershed was derived from the gridded PRISM monthly precipitation model. These monthly precipitation values were compared against the monthly precipitation estimates for the Project, and a ratio was calculated for each month and each station (Table 3-5).

Table 3-5: Monthly Precipitation Correction Factors applied to Project Precipitation based on PRISM

Month	Tenas Hydro	Four-Hydro	Goathorn Hydro	Telkwa Hydro	Bulkley Hydro
Jan	1.84	1.30	1.88	2.06	1.74
Feb	1.68	1.19	1.71	1.89	1.81
Mar	2.00	1.42	2.03	2.29	2.07
Apr	1.81	1.39	1.87	2.05	1.83
May	1.28	1.04	1.26	1.31	1.14
Jun	1.18	1.15	1.23	1.19	1.09
Jul	1.11	1.13	1.16	1.10	1.03
Aug	1.28	1.03	1.28	1.31	1.17
Sep	1.52	1.09	1.53	1.60	1.33
Oct	1.53	1.09	1.56	1.79	1.70
Nov	1.92	1.37	1.94	2.20	1.95
Dec	1.92	1.36	1.96	2.22	1.93

Appendix A

A similar process was employed for temperature. A monthly average temperature for each hydrometric station watershed was derived from the gridded PRISM monthly temperature model. These monthly temperature values were compared against the monthly temperature estimates for the Project, and a correction addend was calculated for each month and each station (Table 3-6).

Table 3-6: Monthly Average Temperature Correction Addends (in degrees Celsius) applied to Project Average Temperature based on PRISM

Month	Tenas Hydro	Four-Hydro	Goathorn Hydro	Telkwa Hydro	Bulkley Hydro
Jan	-0.45	-0.24	-0.52	-0.45	-0.27
Feb	-0.88	-0.37	-0.98	-1.03	-0.73
Mar	-1.27	-0.43	-1.54	-1.66	-0.93
Apr	-1.64	-0.68	-1.96	-2.13	-1.19
May	-1.74	-0.78	-2.03	-2.29	-1.26

Appendix A

The daily temperature and precipitation time series adjusted for each streamflow station were used to calibrate rainfall-runoff model inputs (Section 3.1.7) as well as in the water balance model.

3.1.4 Evaporation

Lake surface evaporation for the Project was developed using the Morton CRWE shallow lake evaporation (SRK 2024a). Based on the Project temperature record, as well as modelled solar radiation, relative humidity and wind speeds from the Smithers Airport station, the estimated mean annual evaporation for the Project is 598 mm. Table 3-7 presents the monthly average lake evaporation rates applied in the model.

Table 3-7: Historical Project Monthly Open Water Evaporation Rates (mm)

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Year
Monthly Evaporation (mm/mo)	0	0	0	64	101	111	120	101	52	0	0	0	598
Daily Evaporation (mm/d)	0		0	2.1	3.3	3.7	3.8	3.3	1.7	0	0	0	n.a

Source: SRK 2024a

The evaporation rates were assigned an adjustment factor calculated for each pond, depending on the dominant wind direction (S-W), and the longest width based on the dominant direction for each pond, according to the following table 3-8:

Table 3-8: Adjustment factor for evaporation rate for each pond of the Project

Changes to evaporation rates for Management Ponds when they become covered are described in Section 3.4.4.

3.1.5 Climate Change

Climate change was evaluated for the Project in terms of rates of change using monthly adjustment factors for three published projection periods. Dates to effect climate change in the model were selected as the center of each published projection period. All scenarios, hydrologic conditions and water management cases include climate change. Selection of climate change scenario for the purpose of the Project evaluation and model are reported in SRK2024a as well as methodologies for developing rates of change are presented.

Daily precipitation rates were multiplied by monthly adjustment factors presented in Table 3-9, where a value of 100% represents the use of historical data, a value less than 100% represents a decrease in monthly precipitation, and a value greater than 100% represents an increase in monthly precipitation. Results indicate a net increase in precipitation for most months with an annual adjustment factor

increasing over time, except for the last decade of this dataset. These values were interpolated to have changes for each decade in the WLBM based on values reported in SRK 2024a.

Table 3-9: Daily Precipitation Adjustment Factors for Climate Change

Date	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Ann

Source: SRK 2024a

Note: Red text reflects a decrease over baseline conditions. A decrease for the decade starting in 2020 indicate that it's decreasing compared to historical baseline average.

Daily temperature changes were included as a net increase or decrease to historical values, as presented in Table 3-10. A value of 0 represents no change from historical temperature data, where a value greater than 0 represents a net increase in daily temperature in degrees Celsius (°C). The annual trend is a net increase in temperature for all months of the year.

Table 3-10: Daily Mean Temperature Increase for Climate Change (°C)

Period	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Ann

Source: SRK 2024a

Climate inputs are drivers of the streamflow modeling in the water balance model, as described in Section 3.1.7. Effects of climate change on streamflow is therefore carried forward through the adjustments to temperature and precipitation.

3.1.6 Snowmelt

The SNOW-17 snow accumulation and ablation model developed by the National Weather Service River Forecast System (NWSRFS) was implemented in GoldSim to model snowmelt for the Project. The main processes included in this model are dividing precipitation into rain or snow, accumulation of snowpack, energy exchange, heat deficit in the snowpack, ground melt and snowmelt as a snow water equivalent (Anderson 2006). Model inputs include temperature and precipitation, based on the selected climate scenario, and input parameters to model a column of snow. Details on model inputs and calibration using a regional snow gauging station are described in SRK 2024a.

The routine in Goldsim produces an excess water term daily, which is the sum of rainfall and snowmelt.

3.1.7 Project Runoff Model

Runoff is frequently presented as the depth of water distributed evenly throughout the watershed area. Since the Project is located within the Goathorn Creek, Tenas Creek, Four Creek, Telkwa River and Bulkley River watersheds, rainfall-runoff models were calibrated for each stream based on the excess water produced from the snowmelt model described in Section 3.1.6.

Constant variables including the lag time, minimum baseflow and recession coefficient, along with monthly runoff coefficients, were adjusted to fit the modelled daily flow to the observed daily flow at each stream. A Nash Sutcliffe Efficiency (NSE) function was included in GoldSim, comparing the modelled vs. observed flow results. Model calibration results are described in SRK 2024a and summarized in Table 3-12.

Impacted catchments, including open pit wall areas and Management Ponds or other ponded areas, incorporated a different set of monthly runoff coefficients. Basin lag and recession were not incorporated

for these types of catchments, allowing all runoff to report to the downstream node in a single timestep. Open pit walls were assumed to consist primarily of exposed mine rock, resulting in fewer losses to infiltration than natural runoff. In this case, a monthly runoff coefficient of 0.8 or 1.0 was used, based on the corresponding values for natural catchments. Pond surfaces were assumed to have runoff coefficients equal to 1.0 year-round. Model inputs for open pit wall and pond areas are also presented in Table 3-12.

Table 3-12: Rainfall-Runoff Model Inputs

Location		Goathorn	Telkwa	Tenas	Bulkley	Four	Project	Open pit Wall	Waterbody
Minimum Unit Baseflow [L/s/km^2]		1.4	4.1	0.43	3.5	0.3	0.69	n.a	n.a

Source: SRK 2024a

Note: runoff coefficients and the baseflow value for the Project are the average for Tenas, Four and Goathorn Creeks

Runoff from overburden stockpiles was assumed to mimic natural runoff conditions, based on the expectation that dumps will be vegetated once completed, and were assigned the same parameters as natural catchments. Runoff for Non-PAG rock are discussed in Section 3.67.

3.1.8 Low Flow Model

Low flow conditions are an important indicator of stream stability in terms of its capacity to provide habitat for fish and aquatic life, as well as other users. The water and load balance model incorporates a baseflow rate calibrated on historical records (Section 3.1.7), which represents typical monthly average low flow conditions. The baseflows were selected based on review of the extended historical records at each hydrometric station, converted to unit baseflows ($m^3/s/km^2$) and applied to each modelled prediction node (SRK 2024a, summarized in Table 3-12). However, the model is unable to simulate more extreme low flow conditions, such as the 7-day low flow for specific return periods.

Low flow conditions were evaluated in two ways:

- Change to low flow conditions were developed external to the water and load balance model based on a ratio of modelled baseflow and the statistical 7-day low flow for a 1 in 10-year return period event (7Q10). Baseline 7Q10 conditions were calculated for each stream based on the extended long-term flow records. A ratio of modelled baseflow over statistical 7Q10 was calculated for each stream or river, based on the unit 7Q10 and the unit baseflow inputs. This ratio was applied to the modelled low flow conditions, which are the same under average precipitation and the 100-year dry conditions based on the constant baseflow input, to calculate the corresponding 7Q10 under post-mining conditions. Percent change relative to Pre-Mining 7Q10 was calculated for each stream node.
- Change to water quality under low flow conditions were evaluated in the Initial Dilution Zone model (SRK 2025c) and are not presented in this report.

3.2 Mine Plan

A mine plan summarizing tonnages and/or volumes of overburden, PAG, and non-PAG rock and PAG processed rock was provided by Telkwa Mining Limited as input to the water and load balance. Cumulative annual volumes of open pit capacity, Non-PAG backfill, PAG material and processed rock are presented in Table 3-13.

Table 3-13: Mine Plan Annual Volumes

Year	Mine Year	Cumulative Non-PAG Backfill Volume (Mm^3)	Cumulative PAG Volume (Mm3)	Cumulative Processed Rock Volume (Mm3)
2021	-1	-	-	-
2022	1	1.16	0.33	0.04
2023	2	2.61	1.54	0.23
2024	3	3.72	3.09	0.41
2025	4	7.55	4.80	0.58

Source: /NACAPR002055/Internal/Water Balance Modelling/Inputs/MasterInputs_TelkwaEA_Rev09_sab_ccm.xlsm

3.3 Catchment Areas

The expansion of mining footprints and resulting reduction in natural catchments contributing to each facility is captured in the varying catchment area timeline. A total of 13 catchment regions were delineated and sub-delineated based on varying land types.

Appendix B includes catchment area figures for each phase of the Project, as well as summary tables with model input areas for each catchment and sub-catchment. Tables are also provided for the changing catchment areas of downstream prediction nodes, while figures for the pre-mining and post-mining prediction node areas are presented in Appendix A.

3.4 Management Ponds

Each Management Pond was modelled with two reservoir elements in GoldSim: one representing the free water volume and one representing the water in the void space of deposited PAG rock and processed rock. Inflows including precipitation and runoff or pumped water from other facilities are linked to the free water reservoir. Outflows from the free water reservoir include evaporation, pumped water to other facilities, and water lost (infiltration) to the void space of placed rock. The only outflow from the rock voids reservoir is seepage into the ground, which is replaced by infiltration from the free water reservoir. This approach enables the separation of water quality in the rock voids from water quality in the free water body, which accounts for the difference in retention time of each facility. Retention time in the rock voids reservoir is the quotient of the void volume and the groundwater seepage rate. The retention time in the void space of the placed waste rock is much longer than the flushing time of the free water reservoir.

Free water reservoirs are used to track the water cover depth above PAG and processed rock to ensure the minimum water cover of 1.0 m is achieved during placement of PAG and 1.5 m after management pond is completed. Water more than target water cover depths is pumped or discharged via spillway from the pond to manage the water level (SRK 2021d). Controls to manage water cover depths are to:

- Activate pump at a rate of 9,000 m^3/day from Tenas Control Pond to any given Management Pond when that ponds' water cover depth is less than 0.50 m.
- Activate pump at a rate of 9,000 m^3/day from any given Management Pond to the Tenas Control Pond when water cover depth exceeds 0.70 m.

Pumping rates were determined based on a monthly water balance for the Tenas Control Pond, presented in the Water Management Design Technical Report (SRK 2021a).

3.4.1 Management Pond Volumetrics

Management Pond capacity and water cover thicknesses are calculated in the model based on stage-storage relationships developed from the final dam and open pit configuration of each facility (Appendix C).

Table 3-14 presents the design levels and volumes for each Management Pond, including the dam crest, spillway invert and cumulative volume, as well as the cumulative PAG rock, processed rock, Non-PAG rock and overburden volumes deposited in each pond. Volumes include total volume occupied by material, including void space. The void volumes were assumed to be 30% of the total volume for placed Non-PAG (and overburden) and PAG rock, and 15% for processed rock. These void volumes are conservative and are expected to be smaller due to natural compaction that will occur during placement in shallow lifts.

Table 3-14: Summary of Management Pond Levels and Capacities

Parameter	NMP	EMP	WMP	Notes
Total Saturated PAG Rock Volume [m^3]	2,386,000	11,561,000	27,432,000	Total volume with water in voids,
Total Saturated Processed Rock Volume [m^3]	3004,000	858,000	2,614,000	Total volume with water in voids,
Top of PAG Rock Elevation [masl]	825.2	847.3	846.9	Based on stage-storage curves (Appendix C)
Non-PAG Rock Cover average approximate Thickness [m]	1.5	1.5	1.5	Selected by TCL and SRK
Non-PAG Rock Cover Volume [m^3]	425,000	1,5750,000	1,422,000	Based on stage-storage curves (Appendix C)

3.4.2 PAG Rock Deposition

The PAG rock deposition schedule by volume for each Management Pond is presented in Figure 3-1.

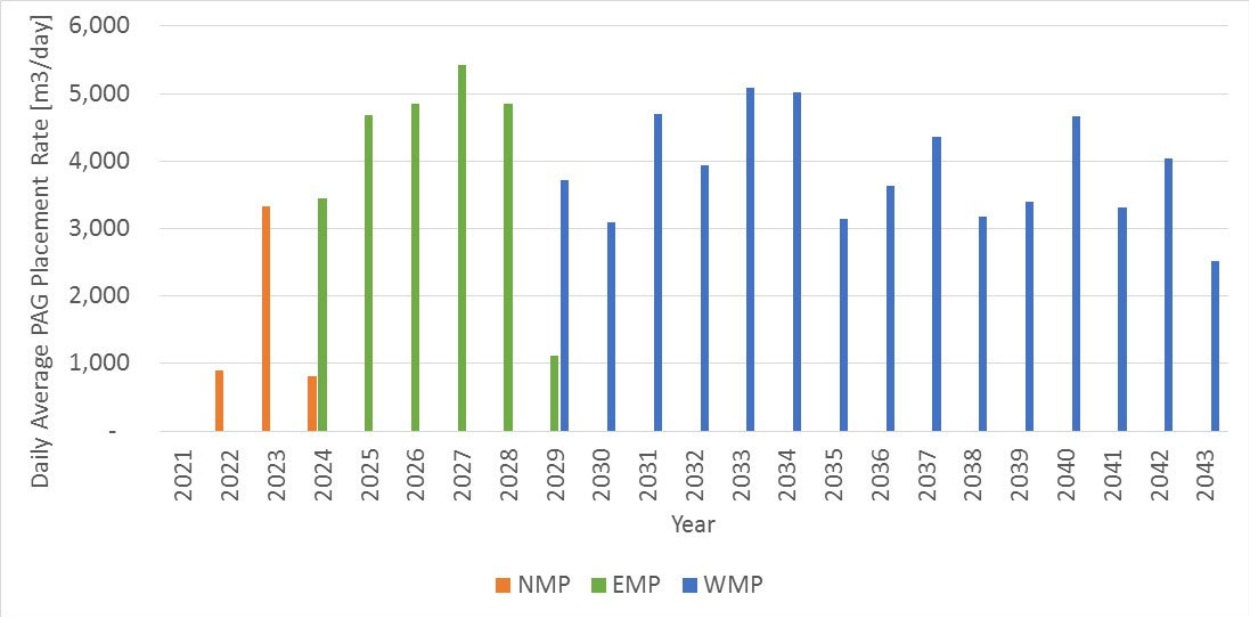

Figure 3-1: Annual Average PAG Placement Rates, m^3/day

Source: /NACAPR002055/Internal/Water Balance Modelling/Inputs/MasterInputs_TelkwaEA_Rev09_sab_ccm.xlsm

3.4.3 Processed Rock Deposition

Processed rock from the CPP is deposited in the active Management Ponds, comingled with PAG rock deposition. The deposition rate of processed coal is 500 m^3/day on average.

3.4.4 Management Pond Covers

Upon completion of PAG rock and processed rock deposition in each Management Pond, a cover system will be constructed to provide the following:

1. Reduce evaporative losses by decreasing the water vapor gradient between the water and atmosphere.
2. Isolate PAG rock from potential human and environmental influence and exposure (i.e. from oxidation from oxygen ingress).
3. Help return the landscape to pre-mining conditions.

The cover design is discussed in Appendix C of the Water Management Technical Design Report (SRK 2021a).

Evaporation rates from the Management Ponds once covered were reviewed as part of the scoping-level cover design. Covers will be vegetated with plant species that meet closure objectives. Based on existing vegetation in the area, a forest of black spruce and aspen will be planted across the Management Pond covers as part of progressive closure of each facility. Actual evapotranspiration rates from similar forests

range from 252 mm/year to 450 mm/year (SRK 2021a, Appendix C). Based on this range, it was assumed that the cover would reduce annual evaporation rates from the Management Ponds to 400 mm/year, or effectively reducing evaporation by 25% over an open-water body. A sensitivity analysis was performed on this assumption, which considered the ability of Management Ponds to maintain minimum water covers without the benefit of the cover (i.e., evaporation rates are equal to open-water conditions). Results are discussed in Section 4.1.1.

3.4.5 Management Pond Dams and Buttresses

Seepage and runoff from Management Pond dams and buttresses will be captured in peripheral ditches and conveyed to the Tenas Control Pond.

The dams and long-term buttresses constructed for each Management Pond will be constructed with Non-PAG rock and overburden. The volume of Non-PAG rock and overburden will be approximately equal throughout the life of mine. Modeling assumes that the water chemistry of buttress and dam runoff and seepage will be the average of the Non-PAG rock and overburden source terms.

Once construction of each dam and buttress are complete, a compacted overburden layer will be placed over each facility to reduce the infiltration rate into the structures from 40% to 10% of precipitation (Section 3.7). This will be followed by layer of growth media and/or soil for final vegetation planting for the decommissioning and reclamation and Post-closure phases. Runoff from the cover will have overburden source term and seepage will have the average of the Non-PAG rock and overburden source terms. Runoff and seepage rates are described with the waste rock hydrology conceptual model (Section 3.7).

3.5 Water Supply

Tenas Control Pond supplies water for the Project. Water is distributed to three locations:

- the Management Ponds to maintain water covers over PAG rock.
- mixing with the treated effluent from the sewage treatment plant discharge during May through October.
- the CPP if not enough is available from the Open Pit sump.

3.5.1 CPP Process Requirements

The CPP water demand is approximately 15,000 m^3/month based on the processing rate of 1.05 million tonnes per annum. A maximum water demand of 130 litres per tonne, and an allowance of 3,625 m^3/month for wash bays and dust suppression (all rates provided by TML) were also implemented. Water is supplied by the sump located downstream of the Open Pit, collecting seepage from the backfill, then from the Tenas Control Pond as a contingency if the Pit sump is unable to provide enough for process water throughout Operations. The water balance completed for the EA shows that the Pit sump can always provide water for process and therefore Tenas Control Pond is not required as a water supply source. A contingency water supply source from Goathorn Creek was also simulated at a rate equal to

2.5% percent of the pre-mining flow rate. This source is configured to be utilized as needed based on low water volumes in the Project area, however the modelled removal of water from Goathorn Creek at node WQS06 occurs throughout the entire Project Operations period for the purpose of the EA. This condition is discussed in model results (Section 4.1.2). The water balance completed showed that this contingency is not required.

3.5.2 Management Pond

Management Ponds are required to maintain a minimum water cover above stored PAG rock and processed rock to reduce the risk of oxidation (Section 3.4) and subsequent acid rock drainage. Water supply requirements for the Management Ponds vary throughout the life of mine and are expected to increase with increasing PAG rock and processed rock volumes. The Management Ponds collect flows from active open pit mining and natural runoff from undisturbed catchment areas. Any deficits are made up by pumping from the Tenas Control Pond, supplied by a pumping system with a capacity of 9,000 m^3/day.

3.5.3 Sewage Effluent

The sewage treatment plant will discharge 5,000 m^3 of treated effluent per year into the tributary of Goathorn Creek (Radloff 2021) during the open-water season (May through September). A dilution rate of 10:1 is required, which will be supplied by a minimum discharge rate from the Tenas Control Pond of 8,300 m^3/month during the discharge period (50,000 m^3/year).

3.5.4 Tenas Control Pond Operations

The Tenas Control Pond design is presented in SRK (2021d), which includes a maximum operating level, an emergency spillway, a minimum operating level, and a contingency storage volume to attenuate storm events. Target volumes are used in the model to trigger actions including discharge to environment or pumps to Management Ponds. The following triggers have been included:

- The design volume of the Tenas Control Pond to its spillway is 1,060,300 m^3. The design stipulates that a minimum of 210,300 m^3 of storage be maintained as contingency for storm events (SRK 2021d). The model does not simulate storm events and uses an upper bound equal to the target maximum operating volume of 850,000 m^3, thereby ensuring that the contingency storage is maintained. Pond overflows in the model represent depletion of contingency storage and the model was optimized to ensure overflows do not occur under average hydrologic conditions.
- Discharge to Goathorn Creek tributary at a rate of 15,000 m^3/d or less is enabled when the Tenas Control Pond volume exceeds 500,000 m^3, which only occurs during open water season months (May to October). This volume was selected as part of pond optimization to avoid depletion of contingency storage during average conditions. Discharge during winter months is prevented through active discharge throughout open water season to avoid reduced dilution capacity in Goathorn Creek at that time.

- Pumping to Management Ponds for water cover supply is disabled when the pond volume is reduced below 50,000 m^3/month. This target volume ensures that a minimum volume is available for sediment control and potentially to provide process water supply.

The Tenas Control Pond stage-storage curve is presented in Appendix C.

3.6 Collection Channel Efficiency

A diversion channel south of the EMP (channel C02) will divert runoff to Four Creek. Ditch bypass contributes to water availability to maintain the Management Pond water cover. A sensitivity analyses was completed on the dich efficiency for this system to ensure water cover could be maintained without relying on ditch bypass (20% of flows).

3.7 Waste Rock Hydrology

The hydrologic model for waste rock storage facilities differs from natural catchment hydrology, due to the lack of overburden and vegetation and the ability of dumps to temporarily store water in their void space (assumed to be 30%). During active material placement, all rock piles, including Non-PAG rock backfill, dams, and buttresses, are modelled as water reservoirs, accumulating inflow until the internal moisture content reaches a specified level. At the specified saturation level, water is assumed to discharge as seepage from the toe of the facilities, where it is captured by collection channels and diverted to downstream management and/or control ponds.

Figure 3-2 presents the conceptual model and Table 3-15 summarizes the model inputs and assumptions.

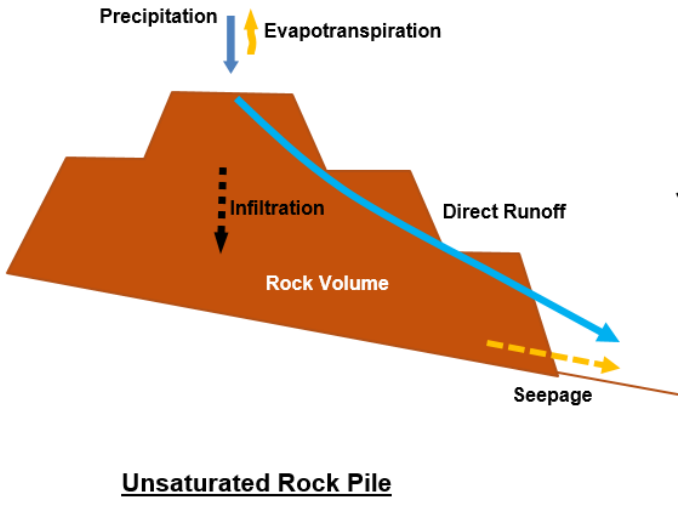

Figure 3-2: Conceptual Waste Pile Model for Unsaturated Rock

Source: Z:\01_SITES\Telkwa Coal\1CT027.003_2020 EA Water Management\500_Water_Balance\ConceptualModel\Planning\TelkwaWB_Planning_01292021.pptx

Open Pit Backfilled Material during Operations and closure

The seepage produced by the backfill (Non-PAG and overburden) during Operations and closure were modeled separately to the SRK Goldsim water balance model. The seepage was estimated in parallel to the development of a source term for the Non-PAG backfill, as described in Okane 2024, and these seepage rates were used as an input to the SRK Goldsim water balance model. Okane used a different framework to SRK to estimate seepage from the backfill with the use of a Wetting-up and Draindown model, but the resulting seepage are of the same order of magnitude as the SRK water balance model and therefore acceptable as inputs for the Goldsim model. Okane's model differs in that the backfill is separated into different mine rock layers, and considers hydraulic conductivity for each layer, as new rock is being placed (Okane 2024).

All Non-PAG rock will be covered with overburden at the end of Operations, reducing infiltration and increasing direct runoff rates, and approximately 70% of total rock volume placed in the open pit will be Non-PAG with the remainder is overburden which is also non-PAG.

Once the mine rock backfill is saturated, seepage is conveyed to the West Management Pond.

Other Unsaturated Rock Piles

Other unsaturated rock piles include the rock dams and buttresses of Management and Control Ponds. The model assumes fixed percentages of precipitation falling on unsaturated rock pile areas will become runoff, evaporate, or infiltrate. Water that infiltrates will be stored in the rock pile until the pile reaches the target moisture content of 7.0% by mass, after which any additional water will discharge as seepage at the toe of the pile.

The mine plan currently states that dams and buttresses will be 30% Non-PAG rock and 70% overburden material by volume. Seepage water chemistry is modeled based on a combined source term developed by SRK assuming the mixed material proportion detailed above (SRK 2024b). This assumes that overburden will be distributed throughout the rock pile, ensuring that water is in contact with both materials equally limiting the chance of preferential flow pathways in the Non-PAG rock which could result in Non-PAG rock dominated seepage water chemistry. Seepage will be lagged with a recession value, like natural runoff rates. A recession value of 0.995 was selected for seepage to simulate a relatively smooth outflow.

Table 3-15: Assumptions for Saturated and Unsaturated Rock Piles

Parameter	Unsaturated Rock	Saturated Rock	Justification
% of Precipitation that Infiltrates	40%	10%, based on Okane water balance modelling	Okane 2024 for Saturated Rock
% of Precipitation as Direct Runoff	10%	Varies per month based on natural runoff rates	
% of Precipitation that Evaporates on surface	50%	50%, based on Okane water balance modelling	Based on monthly water balance

Parameter	Unsaturated Rock	Saturated Rock	Justification
Target Moisture Content which enables Seepage	7%[1]	~30%, based on Okane models (Okane 2024)	Based on SRK experience with operational waste rock dumps (unsaturated)
Runoff Recession Value	0.995	Unknown, part of Okane's internal modelling	Selected to create an even outflow with minimal response to peak rainfall events

Note: [1] 7% by mass of placed rock

3.8 Groundwater

A regional groundwater model was developed for the EA. The model estimated groundwater fluxes, discharge, and recharge from the Project (SRK 2024c). Model results assume that management and control ponds are lined, including the in-pit portions of the WMP which are in contact with overburden. All non-overburden contact areas in the WMP in-pit area are not lined. Two modelled scenarios were considered:

- Expected groundwater scenario corresponds to the best fit model inputs, calibrated against head observations and average annual baseflows in each stream. This condition produced a normalized root mean square error (NRMSE) of 3.2% for hydraulic heads and 3.6% for baseflows (SRK 2024c).
- A sensitivity groundwater scenario corresponds to an outlier condition where the hydraulic conductivities are maximized, while the calibration target is held near the minimum generally accepted in British Columbia (10% NRMSE [Normalized Root Mean Square Error]). This condition emphasizes the potential groundwater flows into the open pit, underneath the waste and water management facilities, and into the creeks (SRK 2024c).

Four snapshot periods were evaluated in the groundwater model:

- End of Year 1: The North Management Pond and Tenas Control Pond are filled with water and PAG rock. No other Management Ponds are active. Connections to the open pit are dictated by the facility footprint and depth currently and active dewatering is occurring.
- End of Year 7: The East Management Pond is filled with water and PAG rock, joining the North Management Pond and the Tenas Control Pond. The open pit extents have increased, and active dewatering continues.
- End of Mining: The West Management Pond is filled with water and PAG rock, joining the North and East Management Ponds and the Tenas Control Pond. The open pit is filled to the maximum level but the open pit is still being actively dewatered.
- Post-Closure: All Management Ponds remain in-place, however the Tenas Control Pond has been breached and no longer stores water. Dewatering from the open pit has ended and the end pit lake and saturated waste rock have formed.

Groundwater connections are incorporated into the water and load balance model based on three components: direct connections to Project infrastructure, changes to stream baseflow, and load transport to streams.

3.8.1 Groundwater Flow Rates through Project Infrastructure

Instantaneous connections occur between the groundwater system and each mining facility, including the open pit, Management Ponds, and the Tenas Control Pond. Groundwater inflows and groundwater seepage loss connected to each facility occur on a daily timestep throughout the model period and are presented in Table 3-16 for the expected case groundwater model scenario and in Table 3-17 for the high case groundwater model scenario.

Table 3-16: Expected Case Groundwater Connections to Mining Facilities throughout Life of Mine [m^3/day]

3.8.2 Changes to Stream Baseflow

The change in water levels within the Management Ponds, Control Ponds, and the open pit affect the groundwater discharge rates to each downstream creek and river. The calibrated rainfall-runoff model included a constant unit baseflow for each major creek, which is applied to each associated prediction node. The baseflows were simplified in the groundwater model calibration (SRK 2024c). To understand the change to baseflows because of the mine, the groundwater model predicted baseline baseflow and baseflow during mining at each prediction node for each scenario. The rate baseflow changed between baseline conditions and mining conditions were directly applied to the baseflow component for each prediction node in the water balance model.

The baseflow dominates the total streamflow during winter months but represents a minor portion of the total streamflow during the open-water season, even during the late summer flows. Baseflow rates in the receiving environment increase or decrease, depending on location in relation to the open pit and the Management Ponds. These changes are linearly interpolated between each snapshot for each prediction node. Table 3-18 presents the rate of change to prediction node baseflows under base case groundwater modeling conditions, and Table 3-19 presents the results for sensitivity groundwater case conditions.

Four Creek baseflow contribution

A recent study (SLR 2025) specifically analyzed data collected for the groundwater system and streamflow regime of Four Creek and developed a water balance model to examine whether Four Creek exhibits perched conditions. Perched conditions would imply that baseflow found in the Creek are disconnected for part or all of the reach of the Creek. Their conclusions suggest that perched conditions are likely "*due to the presence of fine till in the shallow overburden which acts as a low permeability layer inhibiting water from percolating down to the main deep groundwater table.*[SLR 2025]. This implies that changes to the groundwater table due to mining (i.e. drawdown from open pit and raised levels in Management Ponds) would not impact the baseflows in upstream Four Creek.

Other reasons that support their results are as follow:

- *"Vertical hydraulic gradients consistently show negative values, indicating that Four Creek is a losing stream, where water from the creek seeps outwards into the shallow subsurface.*
- *Conductivity measurements along Four Creek show minimal variation except for a few locations. These conductivity measurements suggest contributions to streamflow along Four Creek come from direct precipitation and recently fallen precipitation that arrives at the creek as interflow along the creek's length.*
- *Discharge measurements collected along the length of the channel network do not indicate the presence of consistent groundwater contributions to baseflow."* [SLR 2025]

While these results indicate perched conditions that would disconnect prediction nodes WQS03, WQS20, and WQS21, this report and the WLBM uses the results from the hydrogeological model (SRK 2024c) as these are considered more conservative in terms of changes to Four Creek.

Table 3-18: Rate of Change to Baseflow for Prediction Nodes throughout Life of Mine under Base Case Groundwater Conditions (SRK 2024c)

Node	Stream	End of Year1	End of Year7	End of Mining	Post-Closure
WQS01	Tenas Creek	-0.1%	-0.2%	-0.4%	-0.3%

Source: Z:\01_SITES\Telkwa Coal\1CT027.003_2020 EA Water Management\500_Water_Balance\Inputs\Groundwater\Telkwa_Summary_2020_GW_model_results_Draft_20201203_gf_sab_rev03.xlsx

Under the sensitivity case groundwater model predictions, there is no baseflow to Four Creek at WQS20 and WQS21 (i.e., 100% reduction in Table 3-19). Rate of change to combined streamflow, including runoff contributions, is discussed with the model results.

3.8.3 Contaminant Plume from Project Infrastructure

Water outflows from the Management Ponds, Tenas Control Pond and the open pit into the groundwater system take place instantaneously. However, there is a natural lag between the timing of seepage at the source and seepage being observed within the various stream prediction nodes. Particle tracing within the groundwater model revealed that a portion of seepage reaches the adjacent reach of Tenas Creek before end of mining, but that most of the seepage will not be observed until well past closure.

The model assumes the following:

- Seepage contributions into Tenas Creek prediction nodes WQS02 and WQS22 begin at end of Year 7 and increase linearly to their end of mining.
- Seepage from each Management Pond is delayed 25 years from infiltrating into the facility to reaching prediction nodes. This timing is conservatively early based on the particle tracing results.
- Tenas Control Pond is decommissioned in closure; however, the seepage plume is assumed to continue contributing to the streams for 25 years beyond its decommissioning. Modeling assumes the pond is decommissioned 5 years after the start of closure, and seepage is assumed to continue to discharge to the creeks for an additional 25 years.

The contaminant load reaching each prediction node is calculated based on the percentage of particles leaving each Management Pond, open pit or Control Pond that reach each node under steady-state conditions, considering the dilution of the mine seepage into the total groundwatershed for each stream calculated by the groundwater model. Results for expected case conditions are presented in Table 3-20 and sensitivity case groundwater seepage conditions in Table 3-21.

Table 3-20: Percentage of Groundwater Seepage from each Mining Facility Reporting to Downstream Prediction Nodes under Expected Case Groundwater Conditions (SRK 2024c)

Facility	Node	Phase			
		End of Year1	End of Year7	End of Mining	Post-Closure
North Management Pond	WQS04	0%	0%	7%	67%

	WQS03DS	0%	0%	0%	0%
Saturated Open pit Backfill	WQS02	0%	0%	0%	8%
	WQS03DS	0%	0%	0%	8%
	WQS04	0%	0%	0%	58%
	WQS05	0%	0%	0%	100%
	WQSEA1	0%	0%	0%	42%
	WQS22	0%	0%	0%	25%

Notes:

1. Seepage from the Tenas Control Pond is reduced to zero from 1/1/2074 onwards to reflect the decommissioning of the facility.
2. End Pit Lake discharge to groundwater only occurs under Sensitivity Case groundwater modeling predictions and is therefore excluded from Table 3-20 (base case).

3.9 Water Quality Objectives

The following sections present the proposed in-stream guidelines and end of pipe limits.

3.9.1 In-Stream Guidelines

The long-term average BC Approved Water Quality Guidelines or BC AWQG (ENV 2025a) and the BC Working Water Quality Guidelines or BC WWQG (ENV 2025b) for freshwater aquatic are applied in the evaluation of results from the load balance for most cases, exceptions are laid out below. When both a dissolved and a total guideline was found for a parameter (e.g. nickel), only the dissolved value was kept. Canadian Council of Ministers of the Environment (CCME) Water Quality Guidelines for the Protection of Aquatic Life (CCME WQG) are applied for parameters for which there is no BC AWQG or BC WWQG. WQG values for various parameters depend on the water quality in the receiving environment itself. WQG values are established for different potential receiving environments, based on average background concentrations (i.e., pre-mining conditions). When guidelines depend on hardness, the median hardness from baseline datasets within each creek was selected. Post-mining stream hardness will be higher than baseline and are presented with water quality results in Section 0.

In the case of selenium, the CCME WQG is 0.001 mg/L, which was developed as an alert concentration for early detection of selenium concerns. The BC Ministry of Environment proposed a guideline value of 0.002 mg/L by comparing ambient selenium surface water concentrations in British Columbia (ENV 2014), Alberta and across Canada. With the review of existing toxicological data, the CCME advise that the BC WQG for selenium can be applied across Canada based on jurisdiction's needs and policy goals (ECCC 2021). For this reason, the BC WQG for total selenium was selected as the in-stream target threshold concentration for the Project.

The BC WQG for total mercury is dependent on the in-stream concentration of methyl mercury (MeHg) and can range from 0.02 µg/ for streams where MeHg represents 0.5% or less of total mercury, 0.01 µg/L for streams where MeHg represents 1.0% of total mercury, and 0.00125 µg/L for streams where MeHg represents more than 8.0% of total mercury. Concentrations of MeHg were not measured as part of the baseline monitoring program. The detection limit for total mercury in baseline datasets is 0.0025 µg/L, which is greater than the lowest BC WQG of 0.00125 µg/L for higher proportions of MeHg. The geochemical characterization found mercury concentrations in the humidity cell data were always below the detection limit of 0.01 µg/L. For these reasons, mercury is not expected to be a parameter of concern for the Tenas Project, and the mid-range BC WQG (0.01 ug/L) was used to assess model results.

In the case of total molybdenum, the BC wildlife (ruminant) long-term Chronic WQG was chosen as it was the most stringent (WQG=0.034mg/L) and was applicable for the Project.

There was no BC WQG (Approved or Working), and no CCME guideline for Total Strontium. Therefore, the ECCC FEQG (environment guideline for Aquatic Life was applied as a default (WQG= 2.5mg/L).

Proposed long-term average WQG for the protection of freshwater aquatic life and human health at the Project are summarized in Table 3-22.

Table 3-22: Proposed Long-term Average Water Quality Guidelines for Freshwater Aquatic Life in receiving Environments

Source: https://srk.sharepoint.com/sites/NACAPR002055/Internal/Water%20Balance%20Modelling/Results/20240516_UEA_to%20BAT%20Team/New%20Results%20to%20BAT%20Team/BAT_Calcs_05042024/Telkwa_BAT_assessment_BCWQGused_15072025.xlsx?web=1

Notes:

* Guidelines determined by baseline receiving water quality.
** Short-term maximum BC AWQG are provided for fluoride and total and dissolved iron.
*** All chromium in baseline monitoring data is assumed to be Cr(VI)
**** The guideline for total mercury is dependent on the methyl mercury concentrations of the receiving environment, which is not measured in the baseline data. The mid-range guideline was selected, which assumes a concentration of MeHg that is 1.% of total mercury. since the lowest limit is below the detection limit of the baseline monitoring data.

3.10 Source Term Summary

The load balance considers multiple scenarios of source term combinations, based on alternative rock management strategies and ranges in geochemical source terms.

Two PAG rock exposure scenarios were considered, including a 6-month exposure period (typical exposure), and a 12-month exposure period (high case exposure). The longer exposure period simulates a scenario where the PAG rock may oxidize for a longer period, and therefore generate more soluble load that will be flushed from surfaces when placed in the management ponds.

For baseline surface water and groundwater concentrations 50th (P50) and 95th percentile (P95) source terms were developed. Specifically, seasonal surface water concentrations were applied in the model following the open water season (May to October) and the frozen winter season (November to April).

Base case and high case source terms were developed for non-PAG rock runoff, pit wall rock runoff and coal stockpile runoff. The base case uses geochemical inputs that are representative of the average bulk properties of the mine rock. The high case source term is calculated assuming the drainage from each source is in equilibrium with gypsum (i.e., sulfate concentrations are increased to gypsum saturation) and scaling up elemental concentrations assuming the base case element sulfate ratios are preserved. Additional detail on the source term derivation methods is provided in Appendix E, as well as in Okane's report specifically for the backfill Non-PAG seepage (Okane 2024).

Table 3-23 shows a summary of geochemical source terms developed for the Project where each source term represents an estimate of water quality (mg/L), or parameter loadings (kg/t of rock) contributed by a Project component. The following sections provide more detailed explanations of the source terms included in the load balance.

Table 3-23: Summary of Load Balance Source Terms

Source Term	Units	Applies to
Background Groundwater Concentration	mg/L	Groundwater inflows to open pit and Management Ponds
Background Surface Water Concentrations	mg/L	Applied to undisturbed catchments. Includes separate terms for Telkwa River, Bulkley River, Four Creek, Tenas Creek and Goathorn Creek based on two different seasons: open water season (May to October) and a winter season (November to April).
Backfill Non-PAG seepage	mg/L	Applied to the backfill in the Pit in Operations in Closure, from Okane's 2024 report. Was blended with overburden, and considered progressive cover
Non-PAG Runoff/Seepage Concentration	mg/L	Non-PAG waste rock storage piles, also applied to infrastructure pad surface areas, rail infrastructure area and CPP area. Was blended with overburden for the dams and buttresses
Coal stockpile runoff	mg/L	Applied to temporary coal stockpiles in the Rail Infrastructure area
Open pit wall runoff	mg/L	Applied to exposed open pit wall area
Processed Rock Runoff Concentration	mg/L	Applied to surface runoff volume from coal stockpiles in the Rail Infrastructure area

PAG Rock Flush Rate	kg/t	PAG waste rock backfill to Management Ponds
NAG Rock Flush Rate	kg/t	Non-PAG waste rock backfill to the Management Ponds
Coal Reject Flush Rate	Kg/t	Coal reject to the Management Ponds
Blasting Residue	mg/a	Non-PAG, PAG and coal waste rock volumes
Sewage Treatment Plant Effluent	mg/L	Applied to effluent water from sewage treatment plant into Tenas Pond

Source: Generated in report.

3.10.1 Background Water Quality

Background water quality has been monitored since at least the early 1980s. Baseline water quality monitoring specific to the Project was initiated in 2017 by ERM and has continued since. There is a considerable amount of existing surface water and groundwater quality baseline information available.

Available water quality data were reviewed in support of the EA, and statistics were developed for both surface water and groundwater. Detailed baseline water quality characterization is presented in ERM 2021, including reference to the certified laboratories that conducted sample analysis and quality assurance completed with result compilation, and were updated in 2024 with new available data up to May 2024.

Groundwater Quality

50th and 95th percentile background groundwater chemistry for wells in the Project area was used for groundwater inflows to the open pit. Total or dissolved concentrations for each parameter were applied depending on whether the WQG for the parameter applies to total or dissolved fractions. For some parameters of particular interest for the Project (namely, aluminum, chromium, copper, and iron), both total and dissolved concentrations were applied regardless of whether the WQG for the parameter applies to total or dissolved fractions.

Background groundwater chemistry is summarized in Appendix D. In processing the background and receiving water quality data, values presented as less than the method detection limit were assumed equal to the method detection limit to be conservative.

Groundwater in the overburden and bedrock wells exceed CCME WQG for fluoride on average. Groundwater exceedances of WQG for total metals are likely an artefact of high TSS concentrations and were corrected accordingly to match observed dissolved concentrations. Both overburden wells and bedrock wells exceed the BC WQG for dissolved cadmium on average.

Surface Water Quality

50th and 95th percentile background surface water quality in Tenas Creek, Four Creek, and Goathorn Creek was applied for the Tenas area, as well as excess water from overburden and topsoil stockpiles. Background surface water quality is summarized in Appendix D. The data used to produce the 50th and 95th background surface quality for the Receiving Environment used in the water and load balance model

comes from the water quality baseline study done between 2017 and 2019 (ERM 2019) and updated with water quality data up to 2024.

50th and 95th percentile background surface water quality in each of Four Creek, Goathorn Creek, Tenas Creek, Telkwa River, and Bulkley River was applied as receiving water quality for associated prediction nodes. Receiving environment water quality is summarized in Appendix D.

In processing the baseline water quality data, values presented as less than the method detection limit were assumed to be equal to the method detection limit to be conservative.

Based on grab samples, all surface water streams have occasionally exceeded the BC AWQG for total aluminum and exceedances typically occur during the spring freshet.

Based on grab samples, most surface water streams have exceeded the BC AWQG for dissolved copper, namely Goathorn Creek, Telkwa, and Bulkley River.

Based on grab samples, surface water Telkwa River, and Bulkley River have exceeded the short-term BC AWQG for total iron.

3.10.2 Non-PAG backfill Seepage Source Terms

Supporting information on the geochemical and reactive transport modelling for the Non-PAG backfill source terms can be found in Okane (2024). Concentrations accompanied by seepage rates (as described in section 3.7) were detailed for two cases, a base case representative of typical conditions and a high case for higher loadings due to higher oxidation in the backfill:

The monthly seepage flow rates and corresponding monthly concentrations can be found in Appendix E and in Okane 2024.

3.10.3 Open Pit Wall, Coal Stockpile, and Non-PAG runoff Source Terms

Estimated source term ranges for non-PAG runoff for dams and buttresses of Management Ponds and Tenas Control Ponds, coal stockpile runoff, and open pit wall runoff are summarized in Appendix E. Base case and high case source terms were developed. As described in Section 3.10, the base case uses geochemical inputs that are representative of the average bulk properties of the mine rock and the high case source term is calculated assuming the drainage from each source is in equilibrium with gypsum. Element concentrations are scaled-up in the high case assuming the base case element sulfate ratios.

Open pit wall source terms were generated for three periods throughout the life of mine based on the exposed pit wall area at the end of deposition of PAG rock in each management pond. The model conservatively incorporates a constant source term for pit wall runoff based on the maximum source term concentration for each element across the three periods. Runoff from pit wall areas is expected to be neutral throughout Operations. Modeling assumes that 95% of open pit walls will be covered by end of closure, including all areas that have the potential to become acid-generating.

Source terms for non-PAG rock, coal stockpiles and open pit walls are dissolved element concentrations. Particulate element concentrations were calculated for ponds discharging to the environment based on

an assumed TSS concentration of 35 mg/L and proportions of TSS comprised by various elements based on whole rock analysis for non-PAG and PAG rock. Total element concentrations were calculated by adding dissolved and particulate concentrations (Appendix E).

Particulates were assumed to be filtered in groundwater pathways. All groundwater loadings to downstream prediction nodes were assumed to be dissolved concentrations only.

3.10.4 PAG Rock, Coal Rejects (Processed Rock), and Non-PAG Flushing Terms

Supporting information on the derivation of flushing source terms are presented in Appendix E.

Loading from PAG rock, coal rejects and non-PAG rock used in the management pond covers is assumed to be flushed from the rock when it is placed in the management ponds into the ponded water within an average of one year of placement. Annual PAG rock and unit coal reject and non-PAG rock flushing rates were prepared for the following two scenarios:

- Typical Exposure Scenario: assuming PAG rock is stored on surface for six months.
- High Exposure Scenario: assumes PAG rock is stored on surface for 12 months.

3.10.5 Nitrogen Species derived from Blasting

Nitrogen loading from blasting with ammonium nitrate and fuel oil (ANFO) explosives was accounted for using estimates of explosive usage and the annual tonnages of waste rock. Explosive characteristics were developed based on Fergusson and Leask 1988 and SRK experience (Table 3-24). Typical ammonium nitrate and nitrogen contents, and nitrogen distribution were applied to estimate concentrations of ammonia, nitrate, and nitrite, based on volumes of waste rock reported in the mine plan. Nitrogen losses were decreased from typical values as the mine plan integrates the use of blasthole liners, which would significantly reduce the nitrogen losses in the system (conservatively by a factor of 4). Delayed release and natural attenuation of nitrogen species have not been accounted for within the water and load balance at this time to be conservative, and it is assumed that all nitrogen species are flushed from waste rock on an annual basis.

Table 3-24: Explosive demand and characteristics

Parameter	Units	Value
Powder Factor	g/m^3 waste rock	500
Explosive Loss	%	1.25[1]
Explosives Mix		
% Bulk ANFO	%	75
% Bulk Emulsion	%	25
Quantities in Ammonium Nitrate		
% Nitrogen	% of ANFO	35
Nitrogen Composition		
% Nitrate	%	87
% Nitrite	%	2
% Ammonia	%	11

Source: Z:\01_SITES\Telkwa Coal\1CT027.003_2020 EA Water Management\500_Water_Balance\Model\EA_Modeling\TelkwaEAModel_v24.gsm

Note: [1] This value is assuming the use of blasting liners, based on a mix of ANFO (25%) and emulsion (75%)

Nitrate, nitrite, and ammonia loading were added to each Management Pond or Tenas Control Pond based on the mass of PAG or Non-PAG rock upstream of each facility.

The ANFO model assumptions accounts for operational controls and mitigation measures during blasting to reduce the potential release of blast residuals such as the use of blasting liners. A high case of 5% explosive loss is also used along with the high case source term to look at potential higher nitrogen residue released.

3.10.6 Sewage Treatment Plant

A sewage treatment plant will operate onsite and will discharge treated effluent to Goathorn Creek tributary at a rate of 5,000 m^3/year from May through September. The effluent water quality for parameters in the model are presented in Table 3-25 (Radloff 2021).

Table 3-25: Sewage Treatment Plant Effluent Water Quality

Parameter	Units	Value
Nitrate (as N)	mg-N/L	36.9
Nitrite (as N)	mg-N/L	0.1
Total Ammonia (as N)	mg-N/L	1.9

Source: Z:\01_SITES\Telkwa Coal\1CT027.003_2020 EA Water Management\500_Water_Balance\Model\EA_Modeling\TelkwaEAModel_v24.gsm

3.11 Model Quality Assurance and Quality Control

SRK's quality assurance and quality control (QA/QC) procedures include:

- Verification that all model elements were correctly linked.
- Cross-checking of flows and source terms to ensure model elements not duplicated or missed.
- Cross-checking of model elements and mine phases to ensure the timing of events is accurate as per the EA mine plan.
- Confirmation that the inputs and assumptions were correct and consistent with other EA models.
- Verification of model functions and expressions to ensure are working as intended.
- Professional judgement and experience to evaluate if results reflect the understanding of the conceptual model.

3.12 Uncertainty, Complexity, and Conservatism

Project Case Results and Mitigation Measures

The Project Case model conditions, including the source terms and average hydrologic conditions are incorporated to simulate the expected (typical), or best estimate, based on available information. An appropriate level of conservativism was used for model assumptions as described in the sections above. Mitigation measures were incorporated into the water management plan to address impacts to water quantity or quality.

The alternative assessment cases are intended to represent the reasonable worst case, or the upper bound of expected changes to water quality and quantity. Mitigation measures have not necessarily been incorporated to address potential water quality or quantity considerations identified in the Alternative Assessment cases. Contingency planning and/or adaptive management may be more appropriate if concentrations exceed the Project Case estimates. These contingencies were modelled separately in the mitigation report (SRK 2025b) and assessed in the framework of a Best Available Technology Assessment report (SRK 2025a).

4 Model Results

Model results are presented in the following sections for all assessment cases described in Section 2.4.2.

Results are grouped into sub-sections on water quantity and water quality.

4.1 Project Water Quantity Results

4.1.1 Water Cover

Water balance results are used to determine whether the minimum water cover thickness of 0.5 m during PAG placement can be maintained in all Managements Ponds within 6-months of PAG rock placement and 1.5 m for the rest of the life of mine and closure. The depth of the water cover 30 days after rock placement is also predicted.

Water cover results for each relevant assessment case area summarized in the following sections.

Project Case

Monthly average water cover results for the Project Case are presented in Figure 4-1, including the PAG rock elevation (red), the water surface elevation (black), the monthly average water cover depth (green) and the 30-day lagged water cover depth (blue). A temporary (4-month) reduction in NMP water cover occurred in the winter of 2024 due to the small footprint of the Project at that time. Water in EMP and WMP is stored there prior to adding PAG, but is quickly drawn back to between 0.5 m and 1.0 m for operational purposes during PAG placement. Water is occasionally pumped from Tenas Control Pond to NMP, EMP and WMP while PAG is being placed to maintain water cover, but these pumping events are infrequent. Since the duration of low water cover in NMP is less than 6 months (duration of exposure in source terms), and the water cover is not depleted, results show that the minimum water cover can be maintained in operation and closure. The 30-day lagged water cover is always above 1.0 m under average conditions outside of PAG placement. The system is sufficiently robust for average conditions.

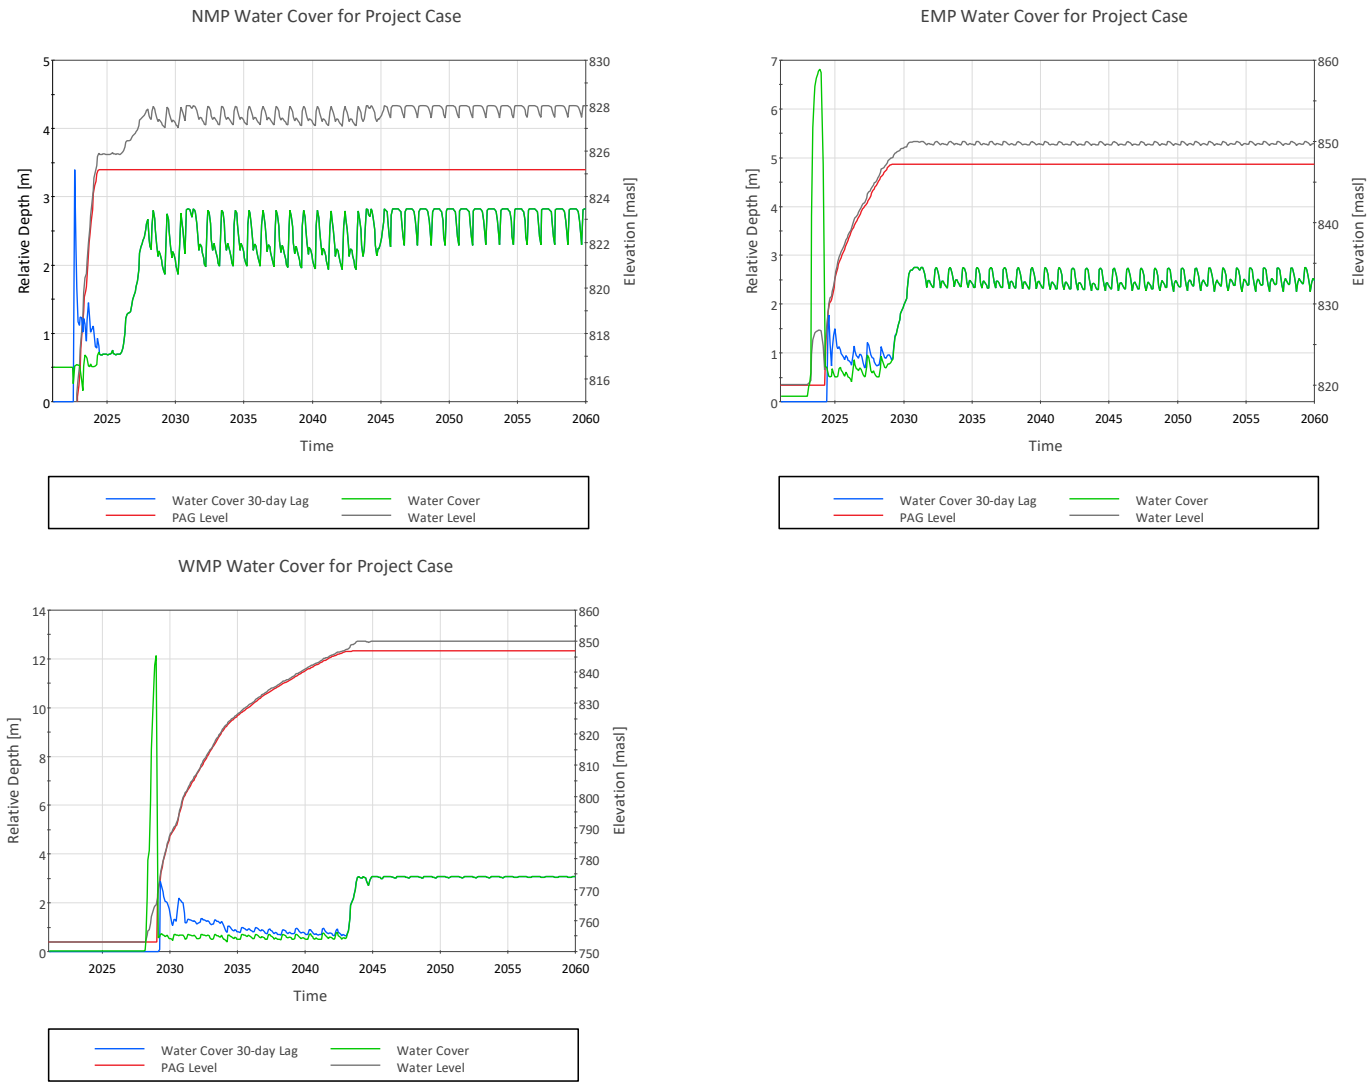

Figure 4-1: Monthly Average Water Cover in Management Ponds for Project Case

Source: CAPR002055 Telkwa Project general EA Support\Internal\Water Balance Modelling\Model\202309_Updated EA Case\2025_submitted_modelresults\TelkwaEAModel_v40_UEA_new hydro_updatedSTs_newGW_BCresults.gsm

Alternative Case 1

Water cover thickness results for Alternative Case 1, with groundwater seepage rates that represent maximized hydraulic conductivity in the groundwater model, are presented in Figure 4-2 for each Management Pond. Like Project Case results, a short-term low water cover period is observed in the NMP during 2024, while the minimum 1.0 m thickness is maintained in all other years throughout operation and closure outside of PAG placement. The 30-day lagged water cover is always above 0.5 m during PAG placement and 1.5 m after completion of the management pond.

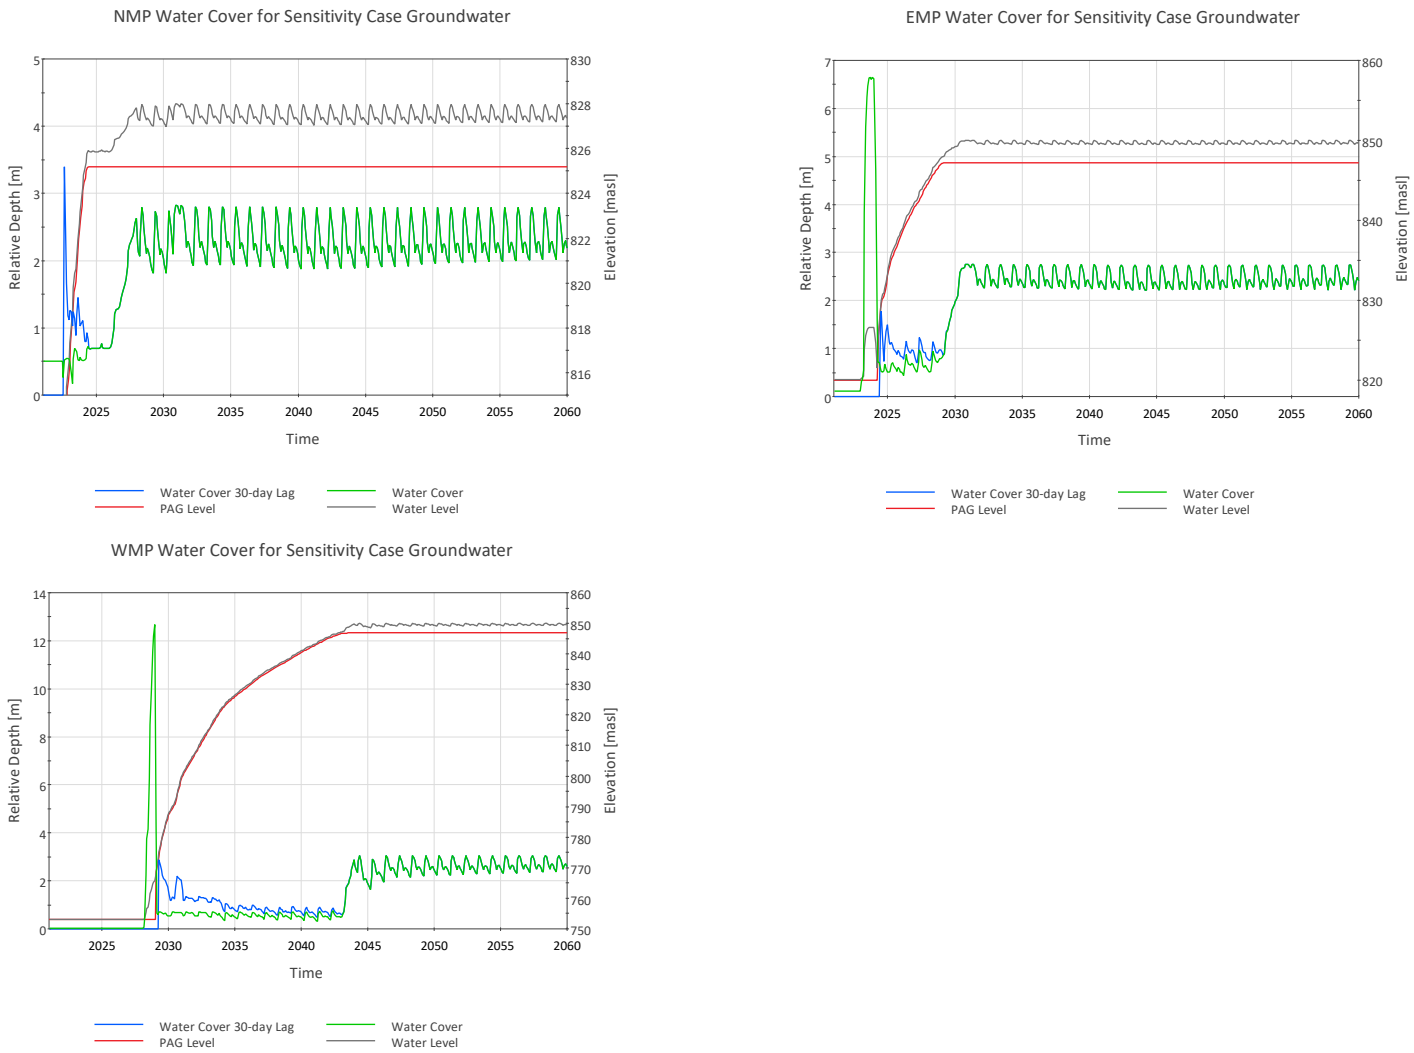

Figure 4-2: Monthly Average Water Cover in Management Ponds for Alternative Case 1 for Groundwater Seepage Loss with increased hydraulic conductivity

Source: : CAPR002055 Telkwa Project general EA Support\Internal\Water Balance Modelling\Model\202309_Updated EA Case\2025_submitted_modelresults\TelkwaEAModel_v40_UEA_newhydro_updatedSTs_newGW_Alt1results.gsm

Alternative Case 3

Alternative Case 3 applies three consecutive 100-year dry precipitation conditions to the Project area. An early Operations period was evaluated (Figure 4-3) as well as a late Operations period (Figure 4-4), for years 2022 through 2024 and 2041 through 2044, respectively. Results show the 10-year operating period around each scenario.

The early Operations period is more critical than the late Operations period. The water cover in the NMP is less than 0.5 m for multiple months in early 2024. In this scenario, the Tenas Control Pond is discharging to Goathorn Creek in May 2024 during freshet. As an operational decision water could be stored to provide additional water cover. In the event of an extreme period of dry years, contingency pumping of 2.5% from Goathorn Creek may also be enabled to provide water supply which has been provided in the model. During these prolonged dry periods, the 30-day lagged cover remains greater than 0.5 m. At no time would PAG rock be directly exposed. For this reason, and accounting for alternative pumping sources or storage of water during freshet, the water management system is sufficiently robust to meet management objectives under the extreme dry scenario considered.

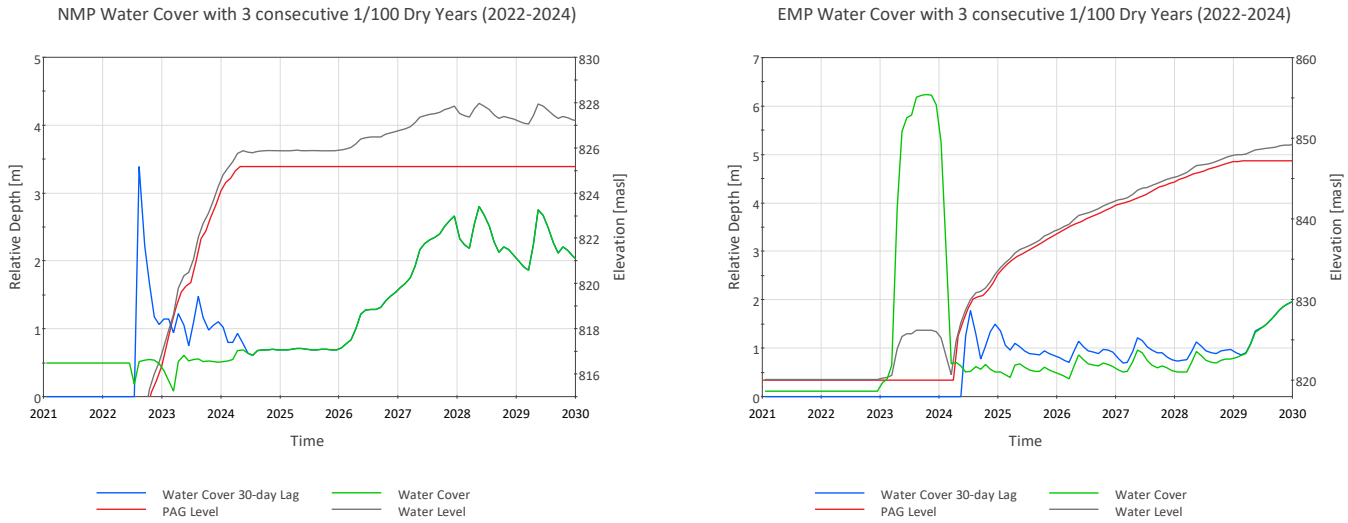

Figure 4-3: Monthly Average Water Cover in Management Ponds for Alternative Case 3 with Three Consecutive 100-year Dry Years in Early Operations (2022-2024)

Source: : CAPR002055 Telkwa Project general EA Support\Internal\Water Balance Modelling\Model\202309_Updated EA Case\2025_submitted_modelresults\TelkwaEAModel_v40_UEA_newhydro_updatedSTs_newGW_Alt3aresults.gsm

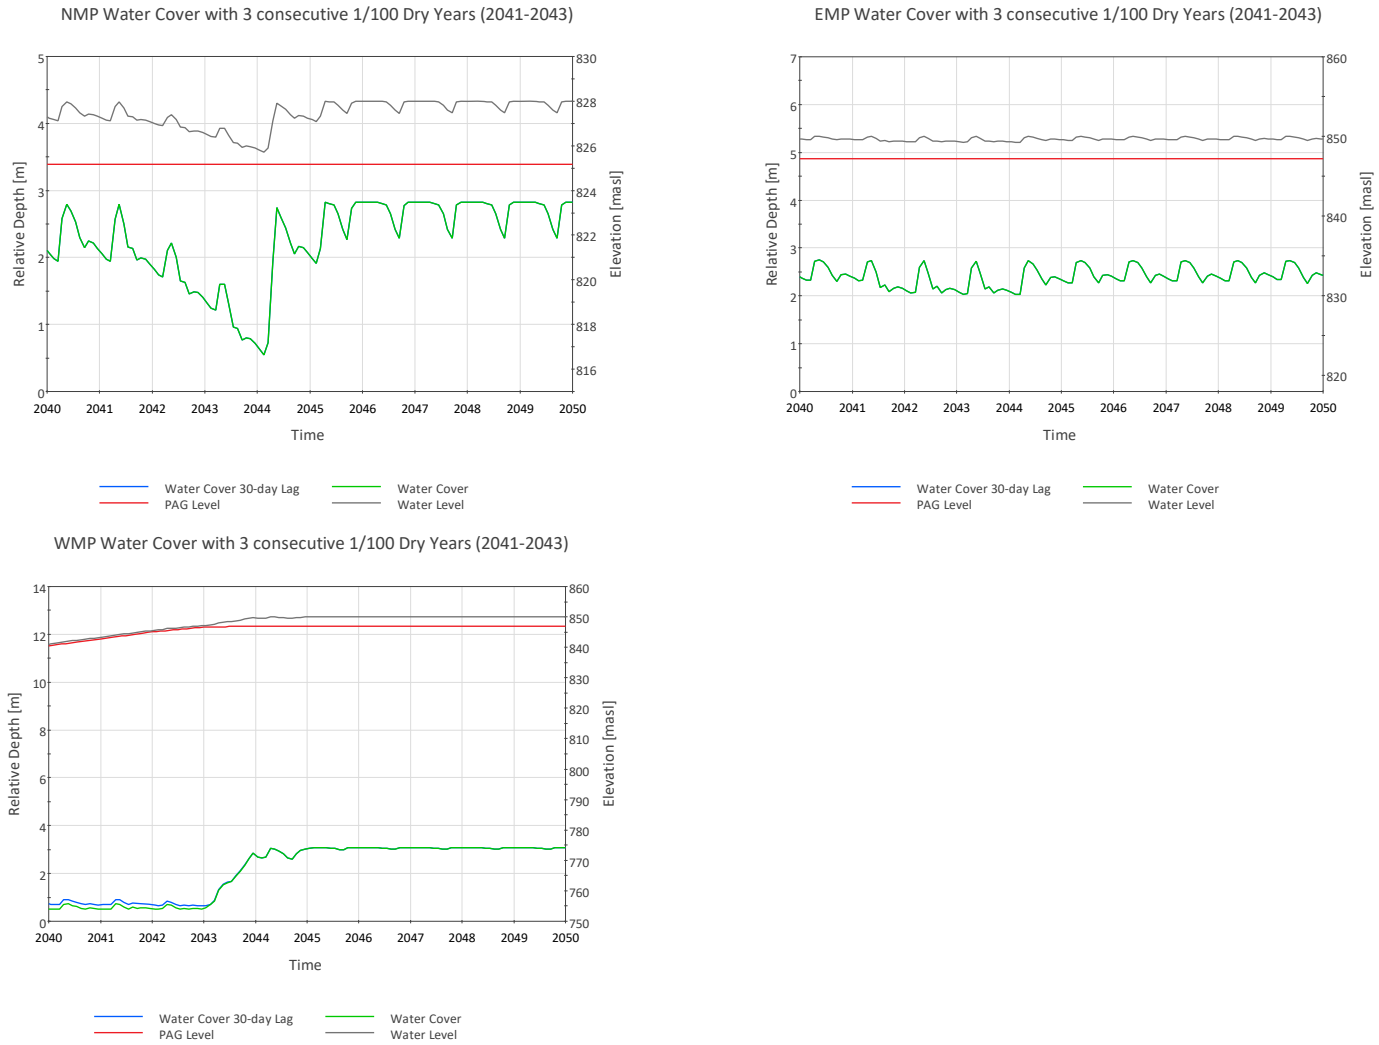

Figure 4-4: Monthly Average Water Cover in Management Ponds for Alternative Case 3 with Three Consecutive 100-year Dry Years in Late Operations (2041-2043)

Source: : CAPR002055 Telkwa Project general EA Support\Internal\Water Balance Modelling\Model\202309_Updated EA Case\2025_submitted_modelresults\TelkwaEAModel_v40_UEA_new hydro_updatedSTs_newGW_Alt3bresults.gsm

Alternative Case 6

Stochastic modeling of climatic variables (temperature and precipitation) over the life of mine was also used to test the robustness of the water management system. On each timestep (daily), the WGEN climate model selects a precipitation, daily maximum and daily minimum temperature value based on historical statistics. A total of 100 realizations of the full mine life were simulated. The statistical distribution of modelled simulations from the Monte Carlo simulation are presented in Figure 4-5, including the 1%, 50% and 99% percentile of results. Note that the plots were cropped to 2050 for ease of presentation, however the full closure period was simulated to 2100. Water cover fluctuations beyond 2050 are like those observed from 2045 to 2050, without being depleted below the 1.0 m minimum thickness.

Results indicate that temporary reductions in water cover below the 1.0 m target are plausible in the Management Ponds, however these periods are less than 6 months in duration and the water cover is never fully depleted (to 0 m thickness). Like Alternative Assessment 3, alternative water supply sources may be incorporated as mitigation measures throughout the operational period if extreme dry conditions persist. Water covers are maintained at the 99% result level in closure.

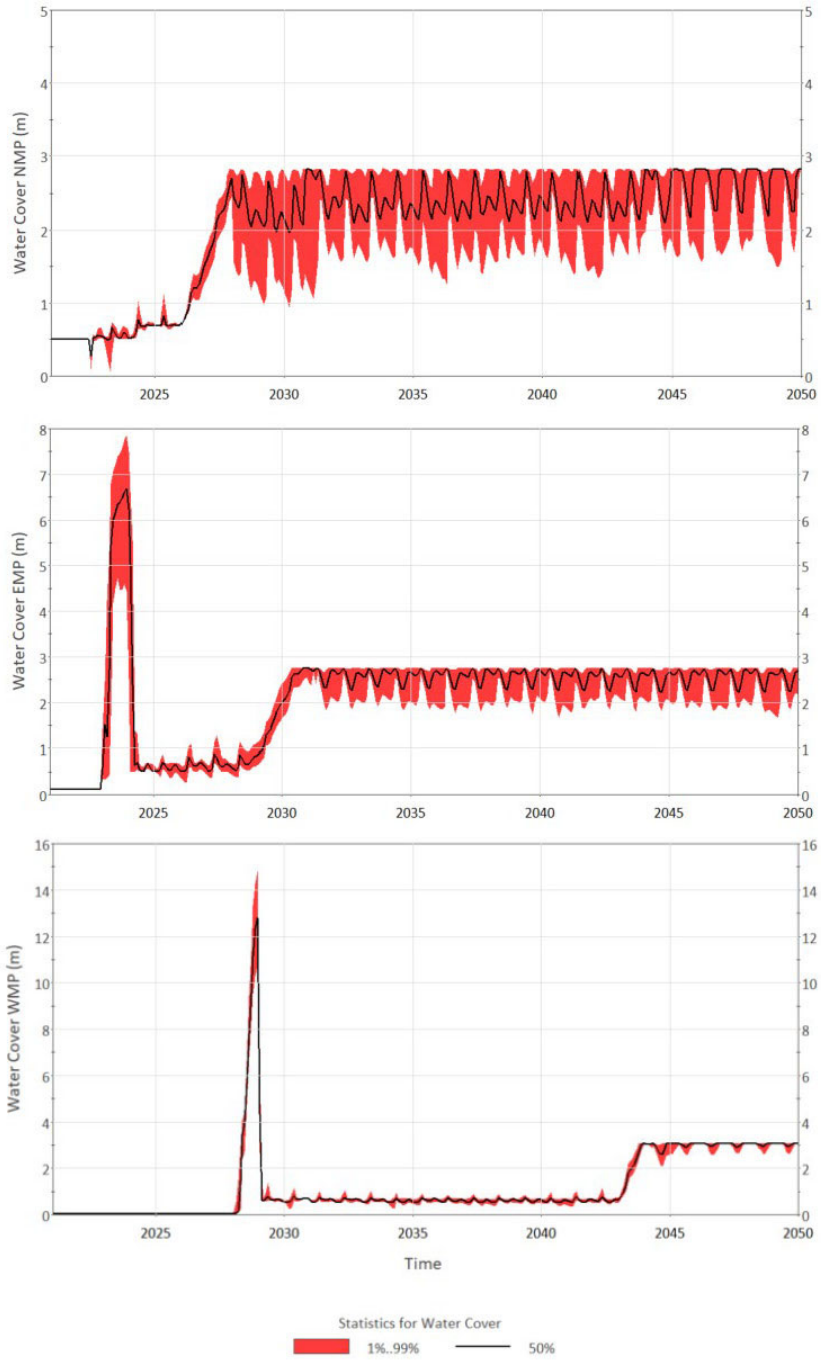

Figure 4-5: Monthly Average Water Cover in Management Ponds for Alternative Case 6 with Stochastic Climate, including the 1%, 50% and 99% Results

Source: : CAPR002055 Telkwa Project general EA Support\Internal\Water Balance Modelling\Model\202309_Updated EA Case\2025_submitted_modelresults\TelkwaEAModel_v40_UEA_new hydro_updatedSTs_newGW_Alt6results.gsm

Additional Sensitivity Analyses

Other sensitivity analyses included:

- An upper-case evaporation analysis was modelled where Management Pond water covers were left without soil and rock covers. This increased evaporation rates to the full open-water values, instead of 25% reduction (as described in Section 3.4.4). Results show that the water cover requirements are still achieved in all three management ponds under average hydrologic conditions.
- The capture efficiency of the diversion channel upstream of the East Management Pond was assumed to be 80%, which results in 20% of upstream runoff contributing to the pond's water cover in perpetuity. A case was modelled assuming 100% diversion efficiency, which reduces the inflows to the water cover. In this case and under average hydrologic conditions, the minimum water covers are maintained.

4.1.2 Process Water Supply

The Open Pit Sump is the primary source of process water for the CPP at a rate of approximately 500 m^3/day. Under Project Case conditions, process water supply is met year-round throughout the operation period. Tenas Control Pond is a back-up source for process water supply but is never needed under average conditions.

Alternative Assessment Case 6 was used to test process water supply under variable annual climatic conditions. Results presented in Figure 4-6 show that water supply can be met even under extreme dry conditions. No water needs to be drawn from Tenas Control Pond under variable annual climate conditions. The 2.5% contingency of water withdrawal from Goathorn Creek was also not required.

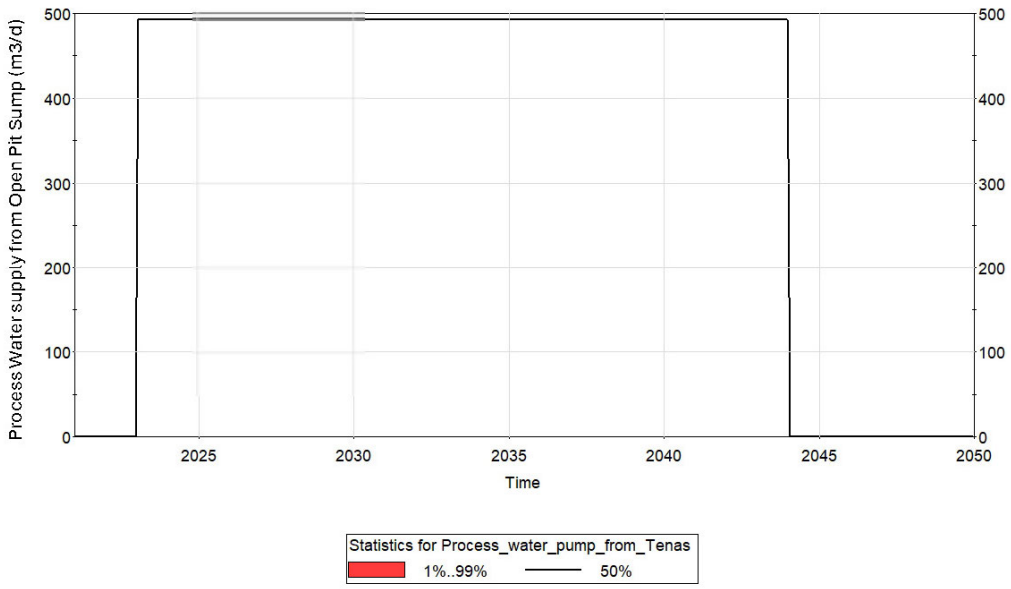

Figure 4-6: Monthly Average Process Water Supply in Alternative Assessment Case 6 with Stochastic Climate, including the 1%, 50% and 99% Results

Source: : CAPR002055 Telkwa Project general EA Support\Internal\Water Balance Modelling\Model\202309_Updated EA Case\2025_submitted_modelresults\TelkwaEAModel_v40_UEA_new hydro_updatedSTs_newGW_Alt6results.gsm

4.1.3 Project Discharge

Tenas Control Pond, the Rail Infrastructure Sedimentation Pond, and the North Management Pond. discharge surface water to the receiving environment (Table 4-1).

Table 4-1: Summary of Discharging Facilities Throughout Life of Mine

Project Facility	Means of Discharge	Receiving Environment	Active Project Stage
Tenas Control Pond	Pump or spillway	Tributary of Goathorn Creek	Construction, Operation, Closure and Reclamation
Rail Infrastructure Sedimentation Pond	Pump of spillway	Tributary of Bulkley River	Construction, Operation
North Management Pond	Spillway	Tributary of Goathorn Creek	Post-Closure

Source: Prepared in text.

The monthly average discharge rates and annual total discharge volumes for the Project Case, Alternative Assessment Cases 4 and 7 are presented in Table 4-2. For Alternative Assessment Case 4, the consecutive wet periods were applied to years where the discharge would be maximized for each facility. In the case of the Tenas Control Pond, maximum discharge occurs in early Operations when the Project water storage capacity is minimized. For the North Management Pond, maximum discharge occurs near the end of the Post-closure model period, when climate change effects to precipitation are maximized and available storage is minimized.

Table 4-2: Project Facility Discharge Rates

Assessment Case	Project Facility		
	Tenas Control Pond	Rail Infrastructure Sedimentation Pond	North Management Pond
Project Stage	Operation and Closure Reclamation	Operation and Construction	Post-Closure
Maximum Monthly Discharge Rates [m³/day]			
Project Case	22,000	240	26,300
Alt Case 4: 3 Wet Years (1) (2)	24,700	240	25,700
Alt Case 7: 10% increased precipitation	24,300	260	28,800
Maximum Annual Discharge Volume [m³]			
Project Case	1,741,000	21,200	1,494,000
Alt Case 4: 3 Wet Years (1)	2,181,000	24,800	1,849,000
Alt Case 7: 10% increased precipitation	2,054,000	23,600	1,775,000
Average Annual Discharge Volume [m³]			
Project Case	1,139,400	19,600	1,342,400

Source: https://srk.sharepoint.com/sites/NACAPR002055/Internal/Water%20Balance%20Modelling/Results/20250403_FEAC_2024/Project_discharge_EASubmitted_20250717.xlsx?web=1

Notes:

1. Three consecutive wet years (approximately the 1 in 10-year wet return period) applied to most critical period, depending on the structure. For Tenas Control Pond and Rail Infrastructure Pond, critical period is 2028-2030 when EMP starts overflowing into NMP, which in turns fills Tenas Control Pond and higher discharge rate, while the critical period is 2068-2070 for North Management Pond which only discharges to environment in Post-closure.
2. The maximum monthly discharge rate is higher for an average year vs 1/10 wet year due to the timing of the precipitation in both representative years chosen. This is because precipitation during the freshet months is higher in the average year but are higher later in the year for the 1./10 wet year throughout the open-water season. However, the maximum annual discharge is higher for the 1/10 wet year vs the average year.

The Tenas Control Pond pumping rate to the tributary for Goathorn Creek was 15,000 m³/day between May and October. The maximum discharge in the Project Case exceeds the pumping rate, which means the spillway is used during Operations. The overflow occurs during spring freshet (May) when the EMP is also overflowing.

The NMP only discharges to the tributary of Goathorn Creek in Post-closure after the Tenas Control Pond has been decommissioned. It discharges over the closure spillway. Highest flows occur in April (i.e. spring freshet).

Changes to Goathorn Creek and Bulkley River from the Project discharges are discussed in Section 4.3.

4.2 Project Water Quality Results

Modelled water quality in the sedimentation ponds and Management Ponds are a function of the following loading sources:

- PAG, Non-PAG, and processed rock loading rates based on volume of rock placed in the Management Ponds per year.
- Water pumped from the open pit, which includes open pit wall runoff and non-PAG rock backfill seepage.
- Natural runoff.
- Seepage from Non-PAG rock and overburden in Management Pond dams and buttresses.

Results were screened against water quality guidelines in the receiving environment. Results were also compared to receiving water baseline water quality statistics. The Management Ponds void water results are compared to baseline statistics and the stream water quality guidelines for which most seepage from a specific management pond is received. Specifically, North Management Pond is compared to Goathorn Creek, East Management Pond is compared to Four Creek, and West Management Pond is compared to Tenas Creek. The Tenas Control Pond is compared to Goathorn Creek water quality guidelines and baseline statistics as surface water from site are directly discharged to Goathorn Creek, as well as results for water contained in the water cover of the Management Ponds. The Rail Infrastructure Sedimentation Pond is compared to the Bulkley River water quality statistics and guidelines.

Monthly average and maximum concentrations are presented for winter and summer periods. Winter is the 6-month period from November to April (frozen conditions). Summer is from May to October (open-water season). Ponds decommissioned during closure and reclamation are only evaluated during Operations. Ponds that operate through Post-closure are evaluated during Operations and closure. Results are presented in Appendix G for Project Case conditions and for alternative assessment cases.

The following parameters were identified as Parameters of Concern (POCs) in the framework of the Best Achievable Technology (BAT) Assessment report (SRK 2025a) as these had maximum monthly values in the effluent end of pipe (surface water discharge or groundwater seepage) equal to or higher than 80% of the water quality guideline calculated for the receiving stream, for the Final EAC Project Case (2024), also called Project Case:

- Nitrate-nitrogen
- Nitrite-nitrogen
- Sulfate
- Aluminum total
- Cadmium dissolved
- Cobalt dissolved
- Copper dissolved
- Iron total
- Molybdenum total
- Nickel total
- Selenium total

- Thallium total[3]
- Zinc dissolved

4.2.1 Management Ponds

The Management Ponds do not discharge directly to the environment during Operations. The Management Ponds discharge excess water via pumps and spillways to the Tenas Control Pond (discussed in Section 4.2.2).

Figure 4-7 and Figure 4-8 present the modelled concentrations of total selenium and nitrate, respectively, in each Management Pond over time for the Project Case, including the water quality in the water cover (solid lines) and the water quality in the rock voids (dashed lines). Results for other parameters are presented in Appendix G (Tables G1-G9), and are compared to water quality guideline for each stream, as outline in Section 4.2.

As discussed in Section 3.4, the water cover and water in rock voids within each Management Pond were modelled as two separate reservoirs. The water cover quality fluctuates seasonally (Figure 4-7). Concentrations increase as PAG rock is added but decrease because of dilution during freshet (May). The water quality in the voids is more constant throughout the year. Peak concentrations in each Management Pond occur near the end of each ponds' operation, prior to the placement of Non-PAG and overburden rock covers. A secondary spike occurs in the NMP from the WMP near the end of Operations. After PAG rock and processed rock placement is complete, the water cover quality in WMP is mainly due to the load received from the Pit backfill, which continues to produce load for the remainder of the modelling period (Okane 2024). Dilution of the void water concentrations (Figure 4-7) occurs more slowly, based on the lower flushing rate controlled by seepage to groundwater. The water quality in the voids is used for seepage water quality to downstream prediction nodes. The travel times from the pond to downgradient receivers is approximately 25-years (see Section 3.8.3).At the end of Operations when Tenas Control Pond has been decommissioned, the NMP will discharge to a tributary to Goathorn Creek.

Other POCs are described in Appendix G (Tables G1-G9).

[3] Thallium total was identified after the BAT report was produced as this is a newly updated BC AWQG (March 2025)

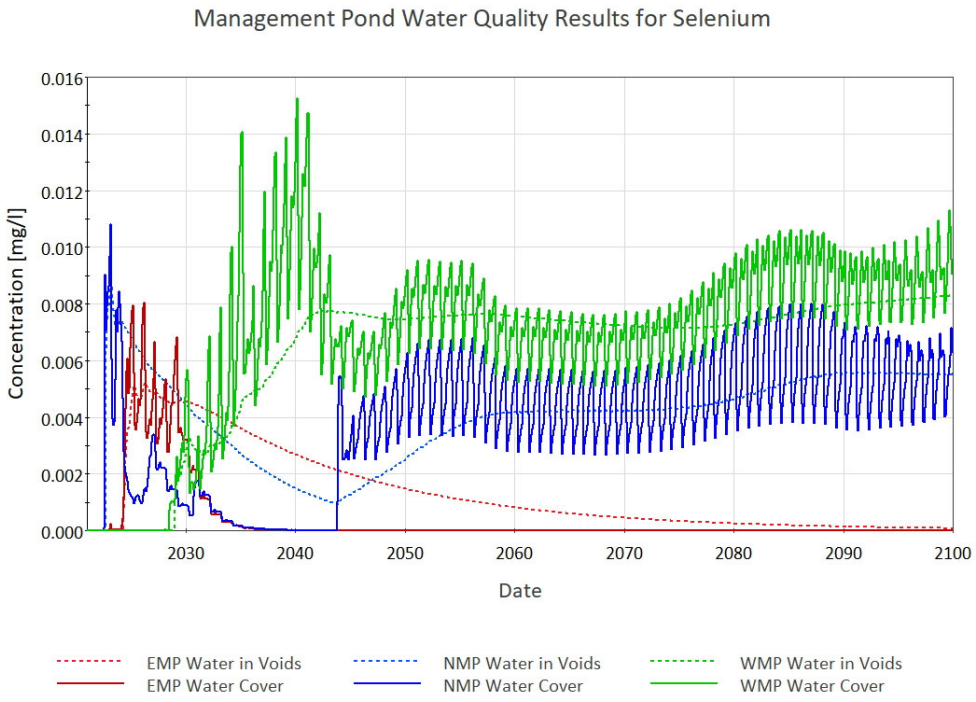

Figure 4-7: Management Pond Total Selenium Results for Project Case

Source: https://srk.sharepoint.com/:f:/s/NACAPR002055/Etr0F_6Ta99CoZITrRJypV0BGK97wtulX609l8LLiQTzXA?e=qNt9UM

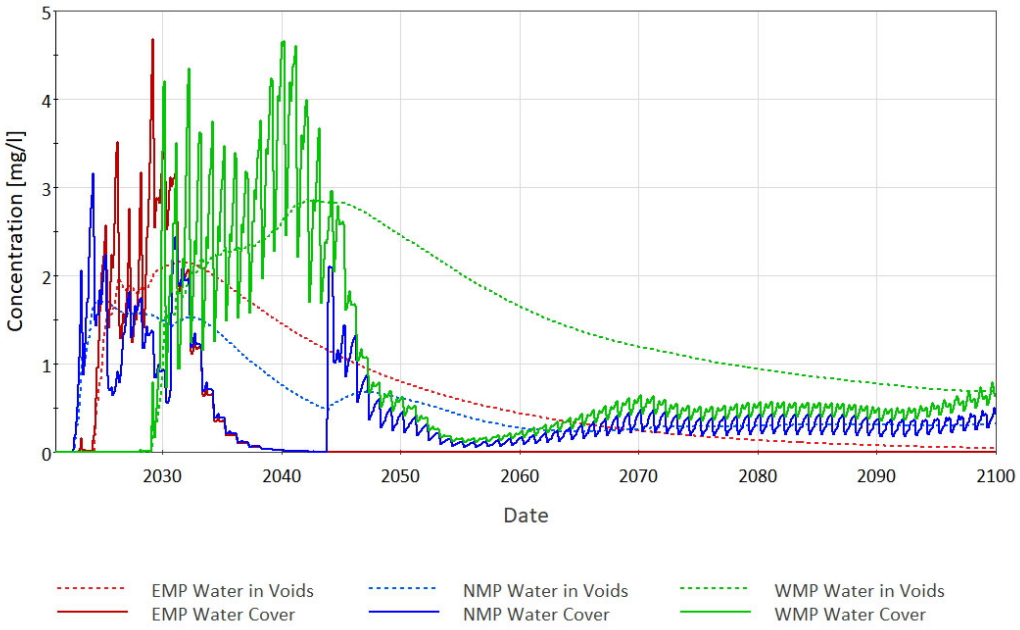

Figure 4-8: Management Pond Nitrate-Nitrogen Results for Project Case

Source: https://srk.sharepoint.com/:f:/s/NACAPR002055/Etr0F_6Ta99CoZITrRJypV0BGK97wtulX609l8LLiQTzXA?e=qNt9UM

4.2.2 Tenas Control Pond

The Tenas Control Pond will discharge to a tributary of Goathorn Creek during Operations until it is decommissioned. Since the Tenas Control Pond is assumed to be fully mixed, the water quality of any seepage is expected to be equal to the pond water quality, and therefore separate seepage water quality is not presented. Water quality results for the Tenas Control Pond are presented in Appendix G. Figure 4-9 and Figure 4-10 present Tenas Control Pond total selenium and nitrate-nitrogen concentrations, respectively. The water volume is also shown in both figures. Results extend through 2050, which includes the pond dewatering period. Tenas Control Pond will be dewatered in 2048 and is decommissioned by 2050.

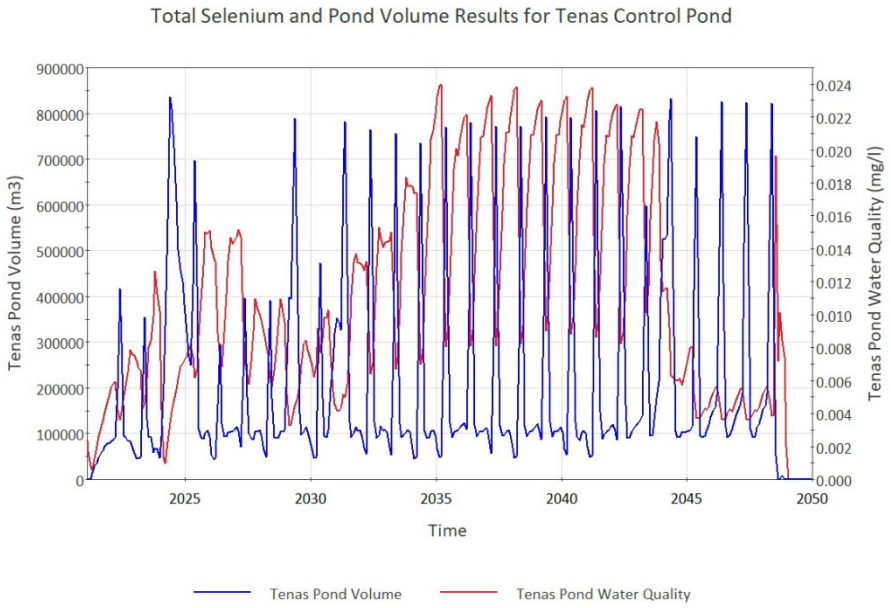

Figure 4-9: Tenas Control Pond Volume and Total Selenium Concentration in Tenas Control Pond

Source: https://srk.sharepoint.com/:f:/s/NACAPR002055/Etr0F_6Ta99CoZITrRJypV0BGK97wtulX609l8LLiQTzXA?e=qNt9UM

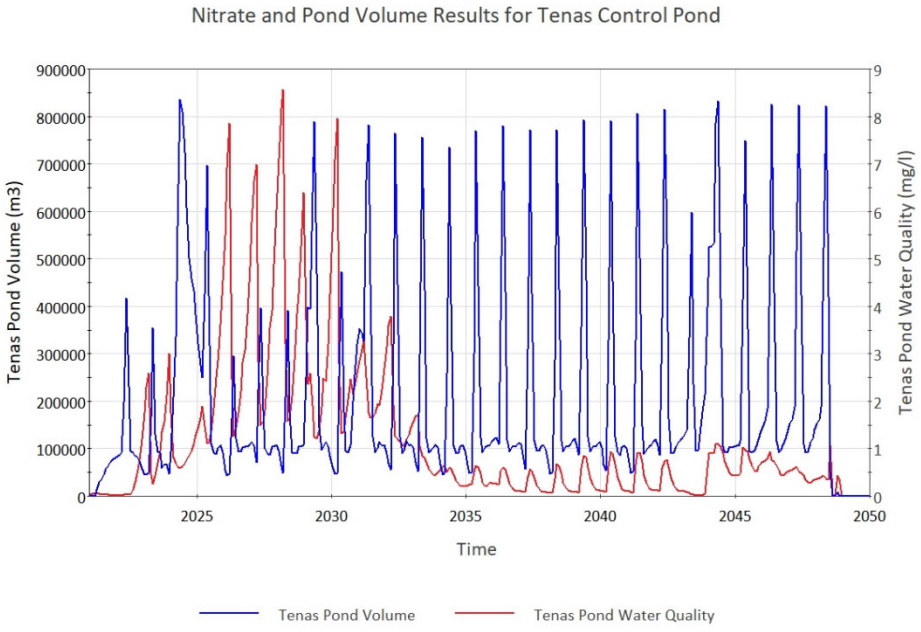

Figure 4-10: Tenas Control Pond Volume and Nitrate-Nitrogen Concentration in Tenas Control Pond

Source: https://srk.sharepoint.com/:f:/s/NACAPR002055/Etr0F_6Ta99CoZITrRJypV0BGK97wtulX609l8LLiQTzXA?e=qNt9UM

Selenium concentrations increase over time in the Tenas Control Pond as the volume of PAG and Non-PAG rock in the Project's footprint expand to maximum extent. Seasonal fluctuations occur.

Concentrations are lowest in freshet (May) each year. The Tenas Control Pond volume is highest during freshet (Figure 4-9). While the selenium concentrations are higher than the water quality guideline for Goathorn Creek, (0.002mg/L), no selenium exceedances are found in the receiving environment (see Section 4.4). Peak concentrations for selenium is 0.023 mg/L towards the end of Operations.

Nitrate-nitrogen concentrations are highest in the first 15 years of Operations after the construction of the Management Pond dams and buttresses. The peak concentration is approximately 8 mg/L, which occurs over winter months when the pond doesn't discharge. The concentration in Tenas Control Pond is above the water quality guideline for nitrate (WQG = 3 mg/L), but never exceeds when discharged in the receiving environment.

Other POCs are described in Appendix G.

4.2.3 Rail Infrastructure Sedimentation Pond

Modelled water quality in the Rail Infrastructure Sedimentation Pond is a function of processed coal rock source terms, with dilution from runoff and direct precipitation. The pond is decommissioned in closure. Pond concentrations increase in the summer months from evaporation. Average water quality in the pond in summer and winter during Operations are summarized and compared against WQG calculated for Bulkley River in Appendix G. Changes to the Bulkley River are discussed in Section 4.4. No exceedances of WQG are expected because of Rail Infrastructure Sedimentation Pond discharges. Figure 4-11 presents the modelled total selenium concentrations at the Rail Infrastructure Sedimentation Pond. Applying the processed coal rock source terms to the full pad area is conservative because coal isn't stockpiled for long before being loaded on a train. It is not likely to oxidize.

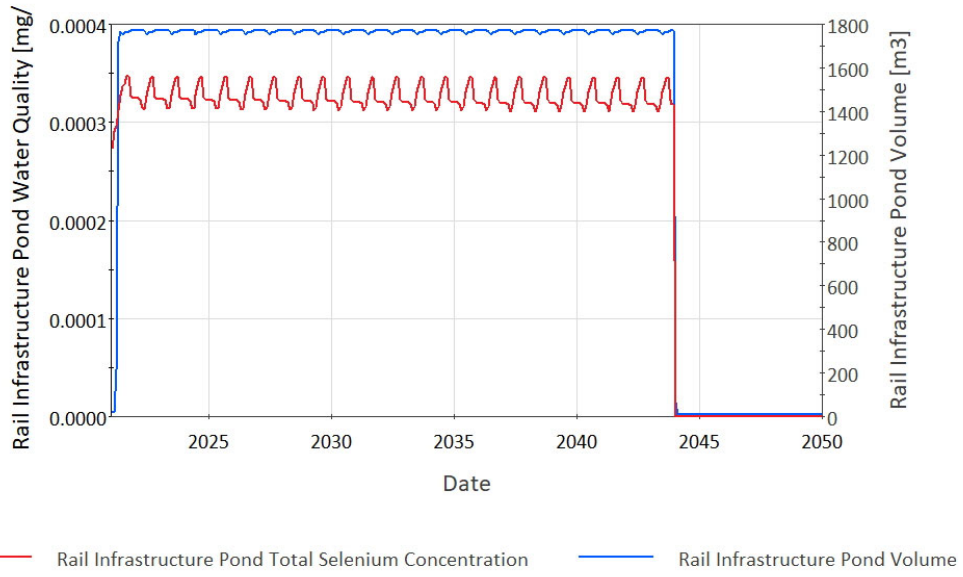

Figure 4-11: Total Selenium Concentration in Rail Infrastructure Sedimentation Pond for Project Case

Source: https://srk.sharepoint.com/:f:/s/NACAPR002055/Etr0F_6Ta99CoZITrRJypV0BGK97wtulX609l8LLiQTzXA?e=qNt9UM

4.2.4 Alternative Assessment Cases

The only alternative assessment case which affects the pond water quality is Case 2, using high geochemical source terms. Table 4-3 compares the maximum monthly water quality in each operating facility for the Project Case and Alternative Assessment Case 2 model conditions. Results for other parameters in Case 2 are presented in Appendix G (Figures G-1 to G-5 and Tables G1-G9), including time series plots of results, similar to those presented in Section 4.2.1, 4.2.2 and 4.2.3.

Table 4-3: Project Water Selenium Results for Project Case and Alternative Assessment Case 2 with High Source Terms

Facility	Maximum Monthly Total Selenium Concentration [mg/L]	
	Project Case	Alt Case 2: High Source Terms
WMP	0.015	0.048
EMP	0.008	0.026
NMP	0.011	0.034
Tenas Control Pond	0.024	0.049
Rail Infrastructure Sedimentation Pond	0.00035	0.008

Source: compiled in the text.

While Selenium concentrations are higher than the water quality guideline (WQG total selenium = 0.002 mg/L) in the effluents, no exceedances are found in the streams in the Project Case (see section 4.4). Discussion for the Alternative cases affecting stream water quality can be found in Section 4.4.2.

Table 4-4: Project Water Nitrate-Nitrogen Results for Project Case and Alternative Assessment Case 2 with High Source Terms during Operations

Facility	Maximum Monthly Nitrate-Nitrogen Concentration [mg/L]	
	Project Case	Alt Case 2: High Source Terms
WMP	4.7	17
EMP	4.7	19
NMP	3.2	13
Tenas Control Pond	8.6	34
Rail Infrastructure Sedimentation Pond	/	/

Source: compiled in the text.

While nitrate concentrations are higher than the water quality guidelines (WQG nitrate = 3mg/L) in the effluent, no exceedances are found in the streams (see section 4.4).Monthly maximum concentrations for other POCs are summarized in tables for the facilities in Appendix G. While these POCs are exceeding their respective water quality guidelines in the effluent, the only exceedances found in the streams for the Project Case is dissolved copper in Goathorn Creek, which is naturally high in the background concentrations and would be similar without the Project's impact. Other results for the Alternative Cases affecting the water quality in the stream can be found in Section 4.4.2.

4.3 Change to Streamflow

The relative change between streamflow for each assessment case and the Pre-Mining Case were calculated using the monthly average water balance model result time series.

Results are discussed in relation to change to mean annual discharge (MAD), seasonal flow distribution, and high and low flows.

4.3.1 Project Case Results for Mean Annual Discharge

The change to mean annual discharge was evaluated using the following thresholds:

- 10% decrease from mean annual discharge.
- 30% increase from mean annual discharge.

The water quantity thresholds were selected based on the BC Environmental Flow Needs environmental risk management framework, which uses a 10% reduction or withdrawal from streamflow as an indicator of stream sensitivity for fish habitat (BC ENV, 2016).

Table 4-5 presents the maximum increase, average change and maximum decrease in MAD based on the Project Case relative to Pre-Mining Case for each Project Stage. Yellow highlighted cells identify prediction nodes and Project stages where an increase in streamflow exceeds 30% and orange highlighted cells identify prediction nodes where streamflow is reduced by more than 10%. Results indicate whether a net increase or net decrease is not expected for a node or Project stage as not applicable (n.a.).

Table 4-5: Percent Change in Mean Annual Discharge for Project Case Relative to Pre-Mining Case, including Maximum Increase, Maximum Decrease and Average Change, over each Project Stage

		% Change in Mean Annual Discharge relative to Base Case Conditions								
		Construction			Operation			Post-Closure

Source: https://srk.sharepoint.com/sites/NACAPR002055/Internal/Water%20Balance%20Modelling/Results/20250403_FEAC_2024/Results_Streams_ChangetoMAD_20250722_CCM.xlsx?web=1

Note: n.a. (not applicable) values represent prediction nodes which do not experience a net increase or net decrease over Pre-Mining conditions

The maximum percent decrease to MAD is greater than 10% at downstream Four Creek node, WQS03DS, and increases by more than 30% in the Four Creek prediction nodes WQS20 and WQS21 during the operation and Post-closure Project stages. Figure F-1 in Appendix F presents a time series of the annual change to mean annual discharge throughout the modelled period at Four Creek prediction nodes.

All other streams are not expected to have greater than 10% reduction to MAD.

4.3.2 Project Case Results for Seasonal Flow Distribution

Changes to seasonal flow distribution are evaluated for each node and Project stage. Results discussed below focus on Four Creek prediction nodes, where MAD could decrease by at least 10% or increase by more than 30%.

Table 4-6 presents the monthly variability of the change in streamflow at Four Creek for the Project Case relative to the Pre-Mining Case, while the results through the life of mine are plotted in Figure F-2 in Appendix F. Results highlight the monthly maximum, average and minimum percent change in monthly streamflow throughout each Project stage.

Table 4-6: Four Creek Project Case Streamflow Monthly Change over Pre-Mining Case

Scenario		Four Creek Monthly % Change Relative to Pre-Mining Case

Notes:

Construction stage is only 1.5 years in duration. Results reflect maximum monthly percent change for months which occur twice in the construction period.
Blank rows represent periods where an increase or decrease in flows is not expected based on model results.

Monthly streamflow during Operations in Four Creek (WQ03, WQS21, WQS20 and WQS03DS) decrease by up to 34% and increase up to 48% (Table 4-6). Diversion channels and mine plan optimizations reduced the Project's footprint as much as practical. However, the open pit and the Management Ponds route water that would normally flow to Four Creek towards Goathorn Creek via the Tenas Control Pond discharge. This reduces the catchment area for Four Creek while the C02 channel diversion increases the catchment area.

Monthly flow in Four Creek varies from upstream to downstream (Table 4-6). WQS21 and WQS20, located adjacent to the East Management Pond, gain flow, or lose insignificant flow during open water season months. During the winter, flow at these locations decreases. Flow at WQS03DS decreases year-round during Operations. This decrease is most apparent during the open water season months.

The causes of these changes in flow are:

- Winter flow at WQS03, WQS20 and WQS21 decreases from the drawdown of the groundwater table by the adjacent open pit. Flow decreases proportionally to the expansion of the open pit (Table 4-6). At closure, the open pit is backfilled and floods. The groundwater table rises but not to pre mining levels. Post-closure flow is lower in Four Creek than baseline conditions.
- WQS03DS is located downstream of the open pit and the East and North Management Ponds. The drawdown of the groundwater table by the open pit is countered by the mounding of groundwater under the East and North Management Ponds. Water seeps from these Management Ponds to the Four Creek in the long-term during Post-closure. Accounting for both conditions, there is still a net reduction of winter streamflow in Operations and a net increase in winter streamflow after mine closure.
- A diversion channel south of the East Management Pond will direct undisturbed surface runoff towards Four Creek throughout Operations and Post-closure. In the Pre-Mining case, this area would report to Four Creek downstream of the outlet of the proposed C02 channel, increasing surface runoff in the upstream portion of the creek (e.g., WQS20 and WQS21). The increased flow in the upstream prediction nodes (WQS20 and WQS21) is highest in early Operations when the catchment area reporting to the diversion channel is largest. As the footprint of the open pit expands, the diversion's catchment area decreases and flow decreases. At closure, a portion of the backfilled open pit will drain towards the diversion channel, increasing open-water season flow by approximately 30% long-term. These percent changes assume 100% of the diverted area reports to Four Creek, however the hydraulic designs include a flow control structure which will limit erosion from individual flow events up to the 1 in 10-year event (SRK 2021a).
- Downstream (e.g., WQS03DS), the effect of the diversion partially mitigates the reduction of streamflow. The catchment area reduction is reduced from pre-mining conditions in Operations and Post-closure.

Appendix F includes the results for prediction nodes in other streams (Table F-1, Table F-2, and Table F-3 for Tenas Creek, Goathorn Creek, Telkwa River and Bulkley River, respectively).

Tenas Creek flow may decrease by up to 11% during low flow periods (April and August) in Operations because of groundwater drawdown and catchment area reductions. The seepage from Management

Ponds counters some of this flow reduction by the end of Operations and into Post-closure. The maximum monthly flow is just 3% less than average monthly flow.

Goathorn Creek flows are expected to be reduced by up to 8% during low flow periods in Operations. Flows downstream of the Project discharge may also increase by up to 6% in Operations and 11% after closure due to routing of water that would otherwise have reported to the Tenas Creek catchment.

The Project may reduce monthly average flows in the Telkwa River downstream of Goathorn Creek by less than 2% in Operations and an increase of 1% in Post-closure due to seepage from Management Ponds. Bulkley River monthly streamflow changes are negligible (less than 0.1%).

4.3.3 Project Case Results for High and Low Flows

The changes to high and low flow were evaluated using Alternative Assessment cases 4 and 5 at each modelled node. Summary tables with results for Alternative Assessment cases are presented in Appendix F.

High Flows and Alternative Assessment Case 4: Three Consecutive Wet Years

In general, the relative change to high flows is driven by the relative change to stream catchment area. As such, high flows are reduced at prediction nodes and stream sections where the catchment area (and MAD as presented in Section 4.3.1) decreases.

The catchment area will increase for two prediction nodes on Four Creek, downstream of the C02 channel discharge. A control structure has been designed to mitigate high flows in Four Creek at prediction nodes WQS20 through WQS21 in Four Creek from C02 high runoff conditions (SRK 2021d).

Discharge from Tenas Control Pond in Operations and North Management Pond in Post-closure may also increase streamflow in Goathorn Creek. This was assessed in Alternative Assessment Case 4 with three consecutive wet years (1 in 10-year wet return periods) to examine the expected discharge rates under more extreme conditions. The results show a potential increase over baseline streamflow of 13% at WQSEA1 and 2% further downstream at WQS05 during spring freshet (Table F-4, Appendix F). Further downstream in the Telkwa River, the change relative to baseline is negligible under consecutive wet years.

The Tenas Control Pond will provide additional attenuation up to the 1 in 10-year flood event, reducing the peak flows in tributaries to Goathorn Creek and downstream in Goathorn Creek. This attenuation has not been incorporated into the water and load balance model but is expected to reduce the expected change in streamflow in Goathorn Creek during high flow events.

Low Flows and Alternative Assessment Case 5: 7Q10 Low Flow

Seasonally flow is lowest in the winter when streamflow is primarily baseflow (i.e., groundwater discharge). The annual low flow is most sensitive to changes in groundwater table and the stream's catchment area. Alternative Assessment Case 5 was also included to evaluate changes to 7Q10 flow rates in stream prediction nodes. Change to low flows are presented in Table F-5 (Appendix F) for each

Project stage, based on the minimum monthly average flow projected for modelled conditions and the most downstream node on each stream.

Extreme low flows are expected to be lower than Pre-Mining conditions by the same percentage as monthly average baseflow. Low flows in Four Creek and Tenas Creek downgradient of the open pit could be reduced by 54% and 7% respectively.

4.3.4 Other Alternative Assessment Cases

Results for the alternative assessment cases are presented in Appendix F and summarized in Table 4-7. Alternative Assessment Case 1 (see Section 2.4.2) is the sensitivity groundwater seepage case. Streamflow changes are likely in Four, Tenas and Goathorn creeks but these changes are negligible in the Telkwa River and Bulkley River (Appendix F, Tables F-6 to F-10 and Figure F-3).

Table 4-7: Summary of Change to Streamflow for Alternative Assessment Cases

Alternative Assessment Case	Stream	Prediction nodes Affected	Project-related Effects
Case 1: High Groundwater Seepage	Four Creek	WQS21 WQS20	Reduction in winter streamflow equal to 100% from drawdown of groundwater table from open pit (Table F-6 and F-7)
	Tenas Creek	WQS22 WQS04	Reduction to MAD remains less than 10%, however monthly flow during Operations decreases more than 10% for the winter months (Table F-6 and F-8) with maximum increases of 30% also for the winter months. Similar effects are also seen in Post-closure.
Case 4: Consecutive Wet Years (High Flow)	Goathorn Creek	WQSEA1, WQS06 WQS05	Increased Project discharge rates to Goathorn Creek, increase the maximum monthly over baseline streamflow by of 13% at WQS06 and 2% further downstream at WQS05 (Table F-4)
Case 5: Low Flow	Four Creek	WQS03DS	Extreme low flows are expected to be reduced over Base Case conditions by the same percentage as monthly average baseflow (Table F-5)
	Tenas Creek	WQS04

4.4 Change to Stream Water Quality

Water quality model results in the receiving environment are presented in summary tables by node and are screened against the natural variability within each stream and the selected WQG.

Results are presented as monthly average and maximum concentrations in winter (November through April) and summer (May to October) to demonstrate seasonal variability. Results are colored red where the average or maximum monthly water quality is expected to exceed the applicable guideline value.

Baseline data (50th and 95th percentile from monitoring results) were also compared against the applicable guideline value.

Appendix G provides each prediction node summary table under the Project Case conditions, as well as for other assessment cases,

The only parameters exceeding water quality guidelines under the Project Case are dissolved cobalt in Four Creek for a period of four years in Post-closure, which did not exceed in the water quality baseline data, and dissolved copper in Goathorn Creek and total aluminum in Telkwa River, which are known to be elevated and exceed water quality guidelines in the baseline data.

Note that water quality results are only presented for prediction nodes that are located downstream of the Project (i.e., receiving discharge or seepage). Prediction nodes upstream of interactions are expected to continue to have baseline or pre-mining water quality. Similarly, prediction nodes on Four Creek and Tenas Creek only experience a change in stream water quality after closure, resulting from Management Ponds seeping to groundwater. For these prediction nodes, only the Post-closure water quality results are presented, and operations water quality is expected to equal baseline conditions. Goathorn Creek, Telkwa River and Bulkley River prediction nodes include operation water quality to express the change from expected Project discharges.

4.4.1 Project Case Results

Chemical constituents (or parameters) were identified in this section if the maximum monthly average concentrations from the model results exceeded the water quality guideline in any month. Summary tables present the prediction nodes which exceed, along with the average long-term winter and summer concentrations and the baseline 50th and 95th percentile concentrations. Results are presented for water quality parameters in Appendix G.

The following general observations can be made for changes in concentrations in the receiving streams:

- Higher concentrations of parameters for which the source is mining (e.g. sulfate, cobalt, selenium, nitrate) occur more frequently during the winter months from seepage discharge to the receiving environment(s) during periods of low flow, and therefore low dilution / assimilation capacity.
- Similarly, an increase in concentrations for parameters for which the source is mining are driven by seepage from the Management Ponds and occur at prediction nodes along Tenas Creek and Four Creek located downstream of the West, North and East Management Ponds.
- The stream concentrations peak approximately 25 years after the peak concentrations are expected in each Management Pond, reflecting the delay in seepage migration described in Section 3.8.3.
- The dissolved cobalt exceedance found in Four Creek occurs only in Post-closure and for a duration of four years. There are no exceedances in the stream expected during Operations. Only the prediction nodes downstream of infrastructure (WQS03DS in Four Creek) experience changes to water quality in these systems, for a few years only.
- Increase to Goathorn Creek water quality parameter concentrations from the Project impacts occur from Project discharge during Operations and typically are only a single month. The only WQG

exceedance recorded in Goathorn Creek is dissolved copper and its source is mainly from background loading. The Project contribution to the load is less than 1% during the exceedance months.

- Model results for total aluminum and dissolved copper in Telkwa show exceedances of the water quality guideline. Like Goathorn Creek, the source of both parameters is the background loading, with the Project's contribution even lower at less than 1%. Furthermore, the Project does not have exceedances for total aluminum in Goathorn Creek.

Dissolved Cobalt

The water quality guideline for dissolved cobalt is 0.00056 mg/L in Four Creek, which is exceeded in Closure for maximum monthly values calculated for the winter months, occurring for four years in the model results. Average winter conditions show modelled results below the water quality guideline. Table 4-8 summarizes the exceedances of WQG for dissolved cobalt.

Table 4-8: Dissolved cobalt Exceedances for Project Case Conditions

Node	WQG [mg/l]	Background Concentration [mg/l]		Project Case Modelled Concentrations [mg/l]				Max Multiplier (2)	Project Stage (1)
		P50	P95	Max Summer	Max Winter	Long-term Average Summer	Long-term Average Winter		
Four Creek									
WQS03_DS	0.00056	0.000050	0.00014	0.00052	0.00063	0.00017	0.00019	1.1	PC

Source: https://srk.sharepoint.com/sites/NACAPR002055/Internal/Water%20Balance%20Modelling/Results/20250403_FEAC_2024/Results_Streams_WaterQuality_UEA_v41_20250717.xlsm?web=1

Figure 4-12 presents the modelled dissolved cobalt concentrations for prediction nodes that exceed the WQG in the Project Case.

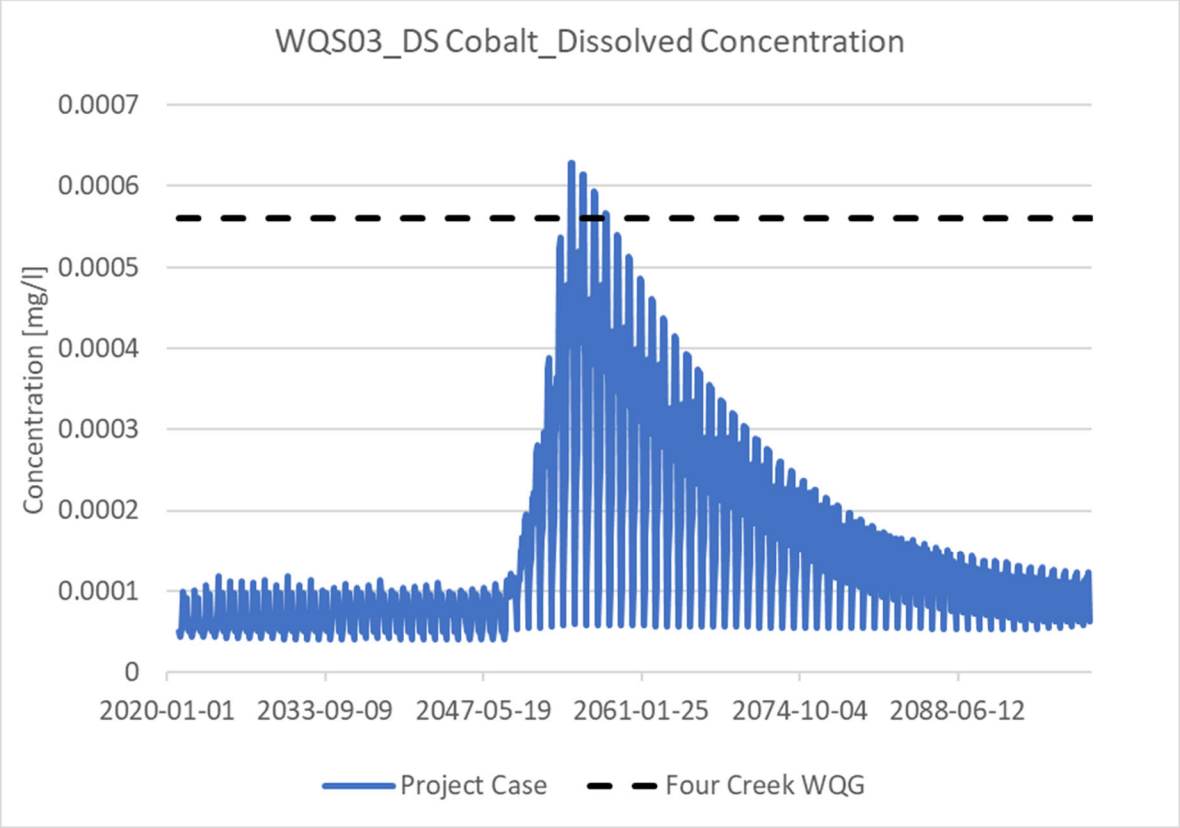

Figure 4-12: Modelled Dissolved cobalt Concentrations for Prediction nodes with Exceedances of WQG in Project Case.

Dissolved Copper

The water quality guideline for dissolved copper is 0.0013mg/L in Goathorn Creek, which is exceeded in Operations and Closure for maximum monthly values calculated for summer and winter months. Average winter conditions show modelled results below the water quality guideline, likely driven by lower P50 background concentrations for that season. Table 4-9 shows exceedances in the baseline data for copper in Goathorn by up to 4 times the WQG for the 95th percentile baseline data in the winter and the summer, and exceedance equal to the WQG for the 50th percentile baseline data in the summer months. The load from the Project contributing to the dissolved copper modelled results is less than 1% of the total load found in the Goathorn Creek.

The water quality guideline for dissolved copper is 0.0008mg/L in the Telkwa River, and it is also exceeded in Operations and Closure, only in the summer months with the maximum monthly model results. Like Goathorn Creek, the Project contributes less than 1% of the load for copper in the Telkwa River. The 95th percentile values from the baseline data exceed by up to 2 times the WQG in the summer and winter months.

Table 4-9 summarizes the exceedances of WQG for dissolved copper.

Table 4-9: Dissolved copper Exceedances for Project Case Conditions

Node	WQG [mg/l]	Background Concentration [mg/l]				Project Case Modelled Concentrations [mg/l]				Max Multiplier (2)	Project Stage (1)

Total Aluminum

The WQG for total aluminum is 0.192 mg/l, which is exceeded in Telkwa River during the summer, likely driven by high TSS values which result in higher background concentrations. Table 4-10 summarizes the exceedances for total aluminum. As noted in the table, the background concentrations from the baseline data exceed for the 50th and 95th percentile values in the summer by up to 10 times the WQG, and the 95th percentile values in the winter months by 1.5 times the WQG. The Project contributes less than 1% of the load for total aluminum in the model results for the Telkwa River.

Table 4-10: Total aluminum Exceedances for Project Case Conditions

Node	WQG [mg/l]	Background Concentration [mg/l]				Project Case Modelled Concentrations [mg/l]				Max Multiplier (2)
		P50 summer	P50 winter	P95 summer	P95 winter	Max Summer	Max Winter	Long-term Average Summer	Long-term Average Winter	
Telkwa River										
WQS09	0.19	0.25	0.04	1.8	0.34	0.26	0.050	0.24	0.036	2.0

2. Maximum exceedance multiplier is a ratio of the maximum monthly water quality result over the water quality guideline (WQG)
3. Results are highlighted in red where they exceed the water quality guideline.

Figure 4-14 presents the modelled total aluminum concentrations for prediction nodes that exceed the WQG in the Project Case.

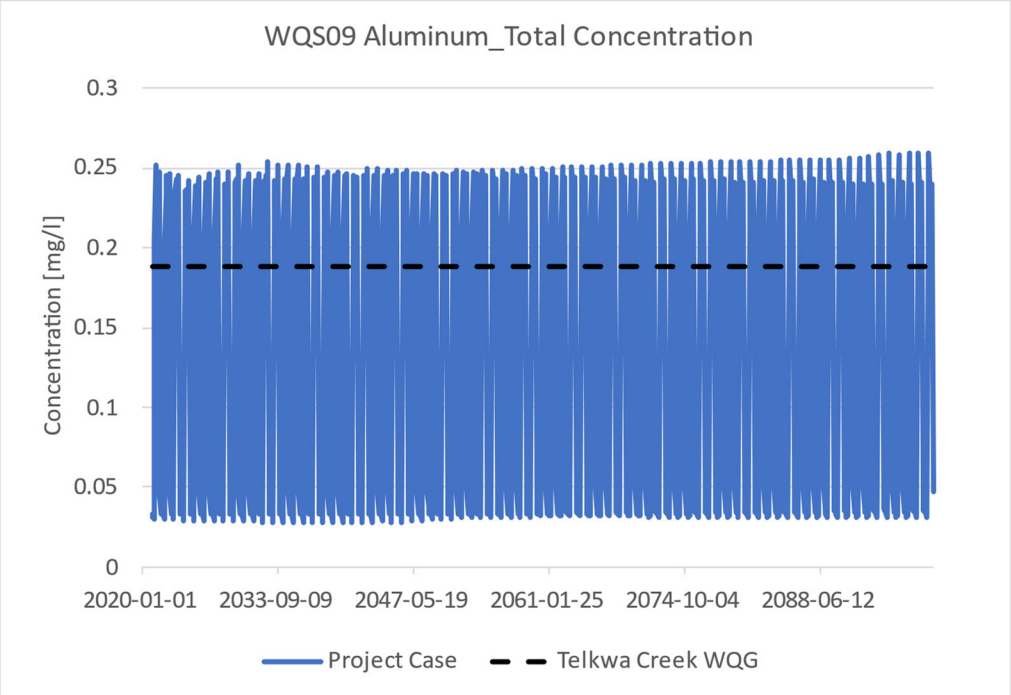

Figure 4-14: Modelled Total Aluminum Concentrations for Node WQS09 with Exceedances of WQG in Project Case

Source: https://srk.sharepoint.com/sites/NACAPR002055/Internal/Water%20Balance%20Modelling/Results/20250403_FEAC_2024/Results_Streams_WaterQuality_UEA_v41_20250717.xlsm?web=1

Additional Observations

Total aluminum baseline 95th percentile concentrations for all streams (Four, Tenas, Goathorn Creeks as well as Telkwa and Bulkley River) are above the WQG. Four Creek 95th percentile baseline concentrations for dissolved iron are also above the WQG. The 95th percentile baseline concentrations for total iron are above WQG for Telkwa and Bulkley River. Dissolved copper 95th percentile baseline concentrations are above the WQG in Goathorn Creek, Telkwa River and Bulkley River.

4.4.2 Alternative Assessment Case Results

Alternative assessment cases include upper and lower range inputs for groundwater, geochemical source terms and hydrology. Each alternative input has been assessed on an individual basis with expected conditions (Project Case) for other parameters. Results focus on the prediction nodes and critical modeling periods associated with each case and are presented in Appendix G, tables G-10 though G-27.

Table 4-11 summarizes the additional changes to water quality under the alternative assessment cases. Results are described in the following sub-sections.

Table 4-11: Water Quality Exceedances under Alternative Assessment Cases

Alternative Assessment Case	Streams Affected	Additional Exceedances (Prediction nodes)	Comments
Case 1: High Groundwater Seepage	N/A	N/A	Despite increased seepage rates from Management Ponds, no additional exceedance is found in Four Creek or Tenas Creek. Decreased concentrations found in Four Creek as decreased groundwater seepage from open pit.
Case 2: High Source Terms	Tenas Creek, Four Creek, Goathorn Creek	Nitrite-Nitrogen (FC-03DS) Dissolved cobalt (FC-03DS, TC-22,04, GC-EA1,06,Ops only, GC-05 Ops and Closure) Total Selenium (FC-03DS, TC-22,04, GC-EA1,06,05 Closure only)	Critical period during low flow (winter months) in closure when Management Pond seepage dominates streamflow
Case 3: Consecutive Dry Years	no change expected	no change expected	Addressed with Low Flow scenario (Case 5). No results presented
Case 4: Consecutive Wet Years	Goathorn Creek only	no new exceedances	Expected Increased Project discharge rate to Goathorn Creek during critical period during EMP overflow, which increases freshet discharge in 2030. No results presented
Case 5: Low Flow	Four Creek	Nitrite-nitrogen (FC-03DS) Dissolved Cobalt (FC-03DS) Dissolved Nickel (FC-03DS) Total Selenium (FC-03DS)	All additional exceedances are driven by groundwater seepage from Management Ponds and effect the Four Creek downstream prediction nodes the most. Overall increases the average long-term values, but the not the monthly maximum values in the winter
Case 7: increased precipitation (10%)	no change expected	no new exceedances	Checked to see if additional exceedances from increased discharge

Notes:
FC = Four Creek, TC = Tenas Creek, GC = Goathorn Creek, TR = Telkwa River, BR = Bulkley River
Prediction nodes identified for each parameter represent additional exceedances beyond what is expected under Project Case conditions.

Alternative Assessment Case 1: High Case Groundwater

Appendix G tables G-10 through G-27 present the stream concentrations under high case groundwater seepage rates for prediction nodes that are downstream of Project facilities. Results reflect a combination of higher seepage rates from the Management Ponds and higher drawdown from the open pit, resulting in an increase in load at some prediction nodes and a decrease in flow at others. This case results in no flow in the upstream Four Creek prediction nodes WQS20 and WQS21 during the winter.

Despite increased load in Tenas Creek, no additional exceedance is recorded in this case. Water quality in the downstream node at WQS03DS in Four Creek improves relative to baseline because of the overall reduction in streamflow from open pit drawdown.

Alternative Assessment Case 2: High Source Terms

Case 2 applies high case geochemical source terms. Appendix G tables G-10 through G-27 present the monthly maximum and average long-term concentrations throughout relevant Project stages.

Additional parameters that exceed the WQG beyond what was exceeded in Project Case conditions include dissolved cobalt, total selenium, and nitrite-nitrogen.

The high source terms are expected to result in exceedances of the total aluminum WQG as well as dissolved copper WQG as it was already exceeding in the Project Case, but both remain below the 95th percentile for baseline datasets.

Additionally, dissolved cobalt is exceeded in new streams for this alternative Case besides Four Creek: it exceeds in Tenas Creek downstream of the Project (WQS22 and 04) in Closure, as well as in Goathorn Creek during Operations (WQSEA1, WQS06 and WQS05) as well as in Closure in WQS05 only.

High source term results are incorporated as the worst-case as part of the initial dilution zone modeling for Goathorn Creek downstream of the Project discharge (SRK 2025c) and in groundwater effects assessment and the Human Health effects assessment.

Alternative Assessment Case 4: Three Consecutive Wet Years (2028-2029-2030)

Three 1 in 10-year wet year precipitation scenarios were repeated in year 2028, 2029 and 2030, to simulate a period where we see the highest discharge during Operations, namely when East Management Pond is full. This results in the maximum Project discharge to Goathorn Creek when water quality is expected to be its worst for most parameters. In this scenario, no additional exceedances beyond what was presented in Project Case were observed.

Alternative Assessment Case 5: Low Flow Conditions

Case 5 assumes that streams experience the 7Q10 low flow condition year-round. Results presented in Appendix G tables reflect maximum concentrations from the model results.

Additional parameters that exceed the WQGs beyond what was exceeded in Project Case conditions include: nitrite, dissolved cobalt, dissolved nickel and, total selenium.

Downstream Four Creek prediction nodes present these exceedances when compared to water quality guidelines for the stream.

Low flow conditions are also evaluated as part of the initial dilution zone modeling for Goathorn Creek downstream of the Project discharge (SRK 2025c).

Alternative Assessment Case 7: 10% increased precipitation

Case 7 assumes increased precipitation by 10% to see how sensitive the water quantity and quality results are with small changes to the modelled average climate conditions. Results presented in Appendix G tables reflect maximum concentrations from the model results.

The only parameter exceeding WQGs in this case was total selenium in Goathorn Creek during Closure. The increase to the Project discharge during Operations does not result in new exceedances, because discharge is restricted to the open water season, when flows are highest. Exceedance in Closure occurs in April when receiving environment flows are often still low.

4.4.3 Additional Water Quality Parameters

Change in water quality to other measurable water quality parameters were evaluated external to the GoldSim model using conservative assumptions and, in some cases, qualitative considerations. Additional parameters include stream temperature, total suspended solids (TSS) and turbidity, pH and alkalinity, conductivity (EC) and total dissolved solids (TDS), and polycyclic aromatic hydrocarbons (PAHs).

This assessment focuses on the smaller streams, including Tenas, Four and Goathorn Creeks. The results presented above for modelled concentrations in Telkwa and Bulkley River show no measurable difference above baseline conditions and therefore the parameters listed above are also expected to remain unchanged.

Stream Temperature

A mass balance approach was utilized to evaluate the change in stream temperature from the Project discharge into Goathorn Creek. Change in temperature is not anticipated to be significant in other streams receiving Project discharge via groundwater pathways.

Temperature predictions in the Tenas Control Pond and management ponds were not developed as part of this work. As a conservative estimate, pond temperature was assumed to be equal to ambient air temperature. Monthly maximum Project temperature derived from long-term time series (SRK 2024a) were applied to the ponds. For air temperatures below freezing, pond water temperature was conservatively assumed to be 0°C. Maximum monthly Project discharge (Table 4-12) was considered from the Tenas Control Pond during operation and the NMP after closure.

Monthly mean flow in Goathorn Creek at node WQSEA1 (SRK 2024a) was considered for in-stream flow conditions, along with monthly average temperature. Stream temperature was obtained from the 2017-2019 baseline monitoring at WQS06 (ERM 2019). The temperature was highest in August, with average and maximum values of 13.8°C and 14.7°C, respectively.

The maximum increase in stream temperature from Project discharge was determined to be 0.4 °C during operation and 1.4 °C after closure (Table 4-12). These changes are within the natural variability of the stream temperature (i.e. difference between average and maximum recorded temperature). Estimates are expected to be conservative in terms of relative change in temperature to the receiving environment. For example, high temperature in April (Post-closure maximum case) is unlikely to occur, since the peak discharge is associated with spring snowmelt, when water temperatures would be close to freezing.

Table 4-12: Estimated monthly temperature change in Goathorn Creek

Parameter	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Tenas Control Pond (OP) [1]												
Pond Temperature (°C) [2]	2	0	3.5	7.2	10.1	20	18.6	16.9	13.7	11.5	1.5	0.5

3. Maximum monthly discharge rate from the pond
4. Corresponds to average temperature at WQS06 based on baseline monitoring (ERM 2019)

Turbidity and Total Suspended Solids

Background concentrations of TSS and turbidity in the Tenas Project streams were obtained from 2017-2019 baseline water quality monitoring (ERM 2019) and updated with dataset up to 2024. The 50th and 95th percentile concentrations of these parameters in Tenas Creek, Four Creek and Goathorn Creek are outlined in Table 4-13. A relationship was developed between TSS, and turbidity based on linear regression considering the baseline monitoring data of streams (Figure 4-15).

Table 4-13: Baseline total suspended solids (TSS) and turbidity in the streams

Parameter	Unit	Four Creek		Goathorn Creek		Tenas Creek		All Creeks	
		P50	P95	P50	P95	P50	P95	P50	P95
Total suspended solids	mg/L	3	21	1.5	16	1.5	37	1.5	26
Turbidity	NTU	1.6	22	1.1	13	1.4	32	1.3	17

Source: https://srk.sharepoint.com/sites/NA1CT027.003/Internal/100_Data_Analysis/2023%20Updates/SurfaceWQ_BaselineData_rev14_cc_CCM_20250514.xlsx?web=1

Note: P50 and P95 corresponds to 50th and 95th percentile concentration, respectively

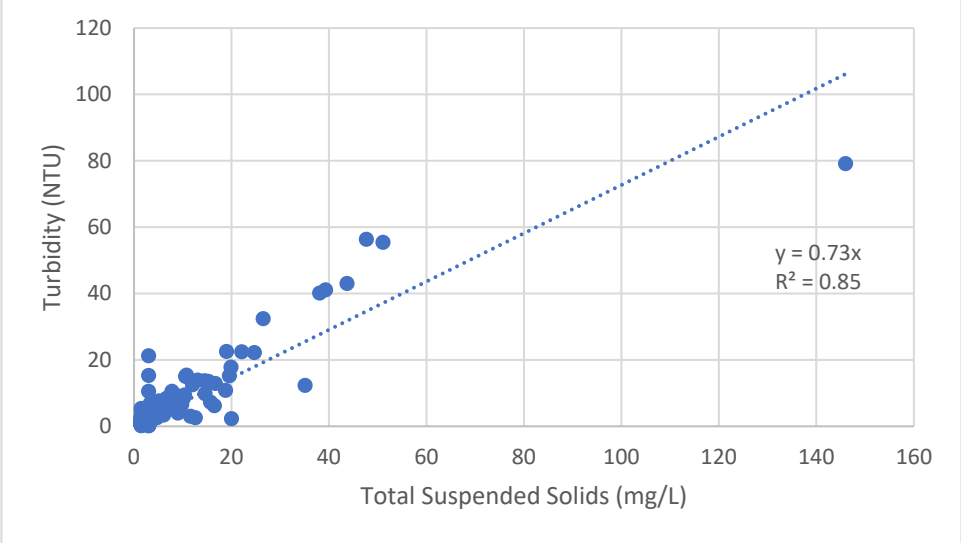

Figure 4-15: Relationship between TSS and turbidity for Goathorn, Tenas, and Four creeks

Source: https://srk.sharepoint.com/sites/NA1CT027.003/Internal/100_Data_Analysis/2023%20Updates/SurfaceWQ_BaselineData_rev14_cc_CCM_20250514.xlsx?web=1

TSS in Four Creek and Tenas Creek is expected to remain unchanged, as there will be no Project discharge to these streams. Suspended particles are expected to be removed during groundwater transport to these creeks. The Tenas Control Pond only discharges in open water period (May – October) during operation and will be decommissioned after closure. Suspended sediments are settled in the pond prior to discharge to a tributary of Goathorn Creek. It was assumed that TSS is discharged from the Tenas Control Pond towards Goathorn Creek at a constant concentration of 35 mg/L.

TSS in Goathorn Creek was calculated based on mass balance approach considering maximum Project discharge with background loading estimated from baseline monitoring. TSS corresponding to the 50th percentile value of 1.5 mg/L was used for Goathorn Creek background concentration. With monthly mean flow representing in-stream flow condition, the estimated TSS varied from 2.2 – 3.1 mg/L (Table 4-14). Turbidity was obtained using the linear relationship shown in Figure 4-15. The maximum turbidity in the creek after Project discharge was estimated to be 2.3 NTU.

TSS and turbidity levels in Goathorn Creek are expected to increase due to discharge from Tenas Control Pond, however the results are within the natural variability of baseline monitoring data (i.e., less than 95th percentile baseline concentration).

Table 4-14: Estimated TSS and turbidity in Goathorn Creek due to Tenas Control Pond discharge

Parameter	Open Water Period					
	May	Jun	Jul	Aug	Sep	Oct
Tenas Control Pond						
Maximum discharge rate (m^3/s)	0.255	0.174	0.101	0.035	0.035	0.035
Goathorn Creek						

Parameter	Open Water Period					
	May	Jun	Jul	Aug	Sep	Oct
Mean flow (m^3/s)	5.1	5.1	3.1	1.6	1.2	1.1
TSS (mg/L) [1]	3.1	2.6	2.6	2.2	2.4	2.5
Turbidity (NTU) [2]	2.3	1.9	1.9	1.6	1.8	1.8

Source: https://srk.sharepoint.com/sites/NA1CT027.003/Internal/500_Water_Balance/OtherParameters/Telkwa_OtherWQ_parameters_v1_rk_20250723_CCM.xlsx?web=1

Notes:

1. Estimated based on mass balance approach.
2. Estimated from the relationship between TSS and turbidity developed from baseline monitoring data.

pH and Alkalinity

Figure 4-16 shows the measured pH and alkalinity in Four Creek, Goathorn Creek and Tenas Creek from the 2017-2019 baseline water quality monitoring (ERM 2019) and updated with data up to 2024, which includes historical measurements from 2006 to 2008. Measured pH and alkalinity in these streams ranged from 7.2 to 8.5 and 26 to 222 mg-$CaCO_3$/L, respectively. The mean pH in Four Creek, Goathorn Creek and Tenas Creek was 7.9, 7.8 and 8.0, respectively.

Based on geochemical characterization of mine water, expected pH in the management ponds is 8.0 (Appendix E). Considering the similar pH in management ponds and baseline monitoring data of various streams, the Project is not expected to alter the in-stream pH or alkalinity.

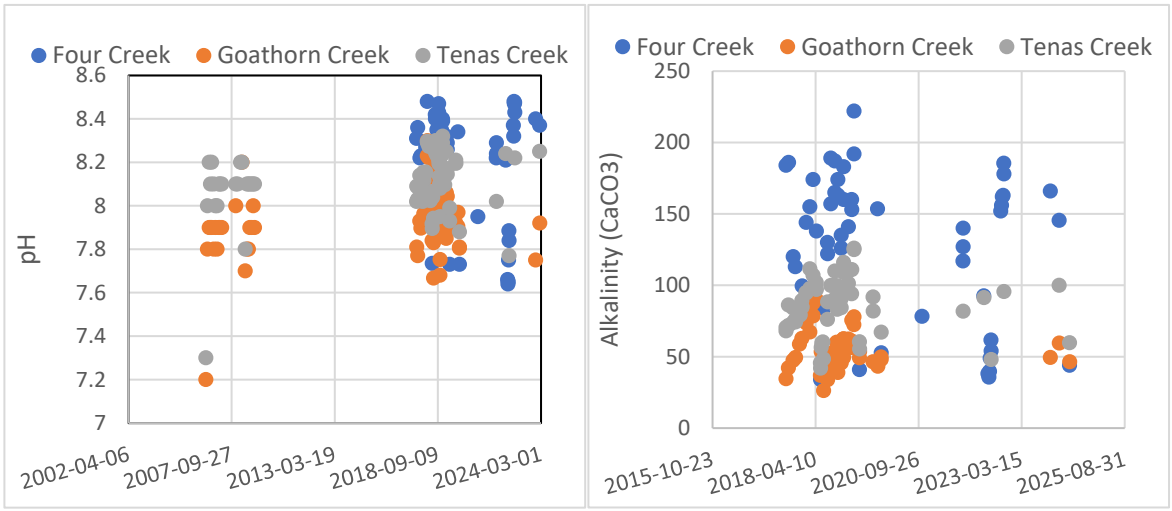

Figure 4-16: Measured (a) pH and (b) Alkalinity in Four Creek, Goathorn Creek and Tenas Creek

Source: https://srk.sharepoint.com/sites/NA1CT027.003/Internal/100_Data_Analysis/2023%20Updates/SurfaceWQ_BaselineData_rev14_cc_CCM_20250514.xlsx?web=1

Specific Conductance and Total Dissolved Solids

Specific conductance (SC) is correlated with total dissolved solids (TDS) and can be expressed by a linear relationship. Based on the 2017-2019 baseline water quality monitoring (ERM 2019) with updated data up to 2024, correlations were developed for Four Creek, Goathorn Creek and Tenas Creek (Figure 4-17). The 50th and 95th percentile background concentrations of TDS and SC in each stream are outlined in Table 4-15.

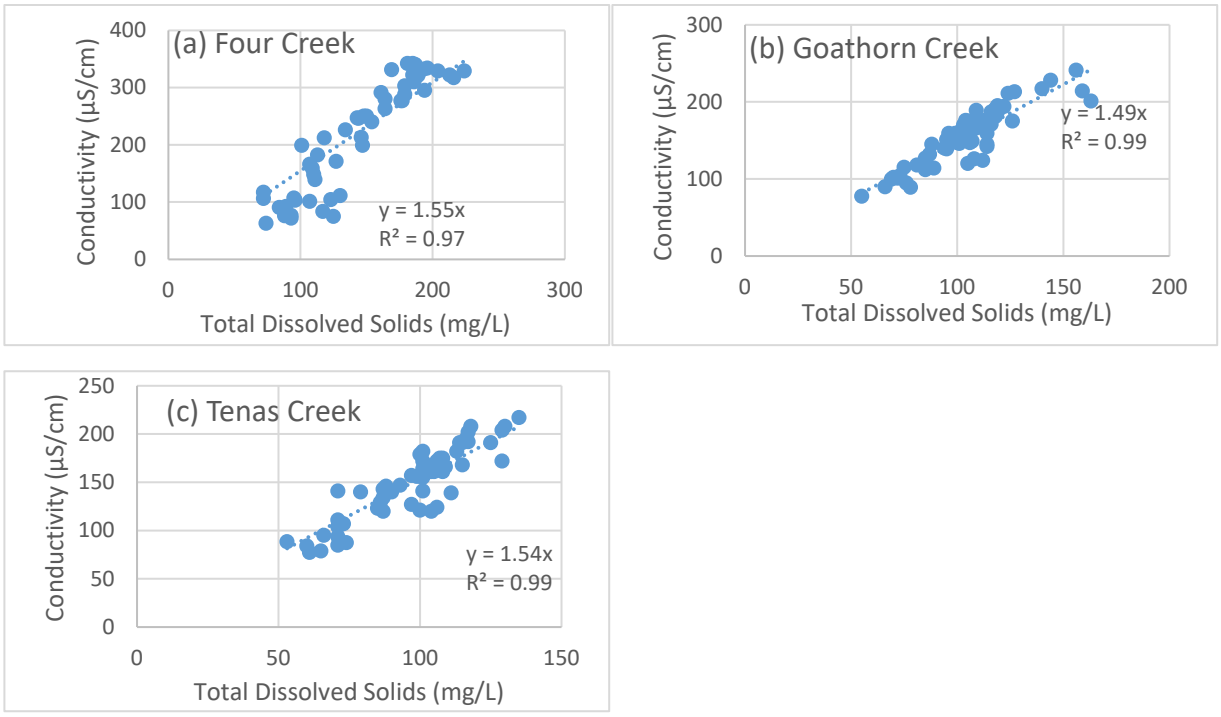

Figure 4-17: Relationship between TDS and specific conductance for (a) Four Creek, (b) Goathorn Creek, and (c) Tenas Creek

The TDS concentrations during Project Operations were calculated based on dissolved metal concentrations and alkalinity from the water and load balance model results for the Project Case. The model results from the prediction nodes with the highest concentrations in each stream were selected, including WQS03DS for Four Creek, WQS04 for Tenas Creek and WQS06 for Goathorn Creek. Calculated TDS concentrations are presented in Figure 4-18.

Maximum TDS in Four Creek, Goathorn Creek and Tenas Creek is estimated to be 233 mg/L, 160 mg/L and 182 mg/L, respectively, which is above the 95th percentile background concentration of individual streams (Table 4-15). TDS reaches its maximum level in Goathorn Creek in Post-Closure when uncontrolled discharges occur from North Management Pond. The maximum winter result is greater than 10% above the 95th percentile background concentration. Summer and winter long-term average TDS in Goathorn Creek are below or close to the 50th percentile baseline concentration. In Four Creek and

Tenas Creek, TDS also reaches its maximum levels in Post-Closure as a result of seepage from management ponds. In both creeks, the maximum values are within 10% of the 95th percentile baseline value. The long-term average TDS concentration in Four Creek is within the stream's natural variability (below 95th percentile), and the winter concentrations in Tenas Creek is within 10% of the 95th percentile baseline value through 2100.

EC was calculated using the regression relationship developed for the Project streams (Figure 4-17) and the calculated TDS concentrations at prediction nodes WQS03DS, WQS04 and WQS06 (Figure 4-18). Long-term average (summer and winter) SC are below the 50th percentile background concentration of individual streams during operation (Table 4-15). The average SC in Goathorn Creek remains below the 50th percentile background level during Post-closure as well. The maximum expected SC in Goathorn Creek is 237 µS/cm, which is above the 95th percentile baseline concentration. Like TDS, this is expected to occur as a result of Project discharge during low flow months in Post-Closure. In Four Creek and Tenas Creek, SC increases in winter months in Post-closure as a result of groundwater seepage from the management ponds. Concentrations are slightly (less than 10%) above the 95th percentile background values in Four Creek during winter months in Post-Closure, however the long-term average concentration (i.e. 2100) is within the baseline range. Tenas Creek concentrations of SC peak in Post-Closure and modeling results during winter months continue to be greater than the 95th percentile baseline value through 2100, though they remain less than 10% over the 95th percentile background values. 10% is considered within the variability of analytical results.

Table 4-15: TDS and SC estimate for Project Case condition

Parameter	Stream (Node)	Background Concentration		Project Stage [1]	Project Case Concentrations						
		P50	P95		Maximum Summer	Maximum Winter	Long-term Average Summer	Long-term Average Winter	Max Multiplier	Long-term Multiplier	Years with >10 % increase above 95th percentile baseline

				PC	160	280	144	221	1.3	1.1	48

Source: https://srk.sharepoint.com/sites/NA1CT027.003/Internal/500_Water_Balance/OtherParameters/Telkwa_OtherWQ_parameters_v1_rk_20250723_CCM.xlsx?web=1

Notes:

1. Project stage acronyms: OP=Operations, PC=Post-Closure
2. Modeling results that are greater than the 95th percentile baseline value by more than 10% are flagged in red

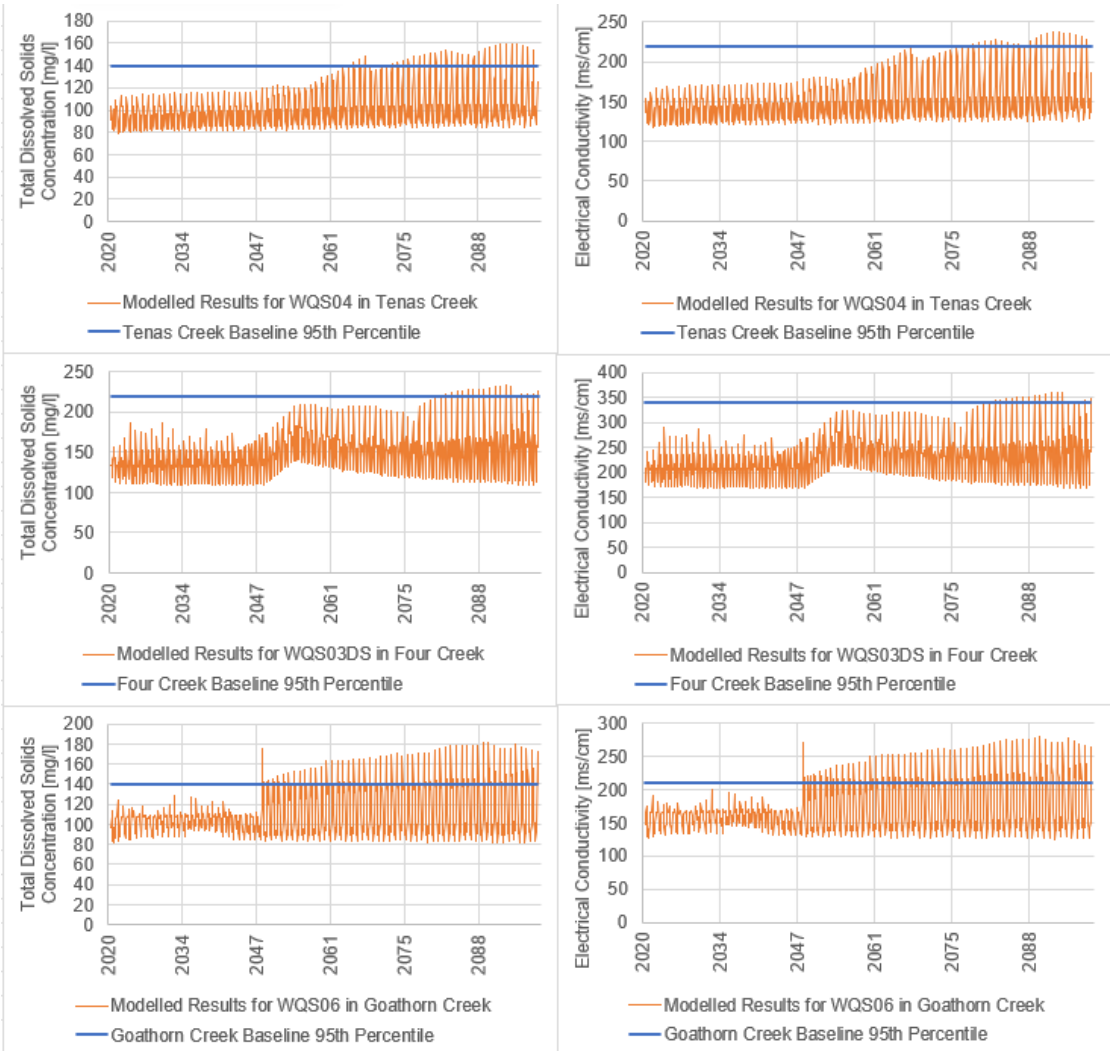

Figure 4-18: Modelled TDS and SC Results for Tenas Creek, Four Creek, and Goathorn Creek

PAHs

Polycyclic Aromatic Hydrocarbons (PAHs) will be controlled and mitigated through emergency response plans and spill response plans. No change in stream PAH concentrations is expected.

4.4.4 Exceedance Drivers and Mitigations

The sources of total selenium, dissolved cobalt and dissolved nickel is the runoff and seepage from Non-PAG rock backfill in the open pit, the buttresses, and Management and Control Ponds dams. Non-PAG areas will be covered with overburden progressively throughout Operations and into closure and reclamation. This will limit the long-term loading.

The source of nitrite-nitrogen is the blasting residue released with runoff and seepage from both PAG and Non-PAG rock. The blasting residuals model assumes a fixed percentage of load from the ANFO/Emulsion mixture is released per mass of placed rock. Assumptions are consistent with Best Practice and available literature (Ferguson and Leask 1988) but are expected to be conservative.

Other exceedances were mainly due to baseline concentrations being naturally high, such as for dissolved copper and total aluminum. Continued monitoring of the streams for their characterization has been ongoing since 2017 on a regular basis.

5 Summary of Receiving Environment Results

The following sections summarize the model results for the receiving environment. Results are discussed by stream (5.1) and in context within the RSA (5.2).

5.1 Summary of Model Results for Streams

5.1.1 Four Creek

Results indicate the following for Four Creek:

- Streamflow is reduced from baseline because the Project footprint occupies a portion of the existing Four Creek catchment.
- During open-water season months, streamflow is increased over baseline by diversions, capturing and diverting upstream runoff to portions of Four Creek.
- During the winter, baseflow is reduced in upstream prediction nodes during winter months from the open pit drawing down the groundwater table.
- Seepage from the Management and Control Ponds may increase the winter baseflow and result in elevated water quality concentrations for constituents of potential concern.

Based on conservative modelling of Four Creek (i.e. not accounting for the perched groundwater system, as described in Section 3.8), modelled results show that the Project will affect Four Creek. MAD downstream of the C02 channel will increase. MAD will decrease downstream because the Project decreases the size of the Four Creek catchment. However, based on most recent report examining whether Four Creek is perched (i.e. disconnected from the groundwater recharge) [SLR, 2025], it has shown that the upper reach of Four Creek is very likely perched, and therefore would not be directly impacted by the decrease in size of the Four Creek catchment.

High case groundwater seepage rates presented in Alternative Assessment Case 1 could reduce baseflow during winter months at prediction nodes directly downstream of the open pit (WQS20 and 21). However, based on most recent report examining whether Four Creek is perched (i.e. disconnected from the groundwater recharge) [SLR, 2025], it has shown that the upper reach of Four Creek is very likely perched, and therefore would not be directly impacted by the decrease in size of the Four Creek catchment.

Baseline water quality monitoring show that exceedances have occurred in Four Creek for total aluminum, and dissolved iron. After closure, groundwater seepage from the East Management Pond results in exceedance of water quality guidelines for dissolved cobalt during the winter months (4 years in total) and otherwise increases of concentrations for modelled parameters, in the downstream reach of Four Creek (WQS03DS). Alternative cases (case 2 and case 5) showed additional exceedances for the following parameters:

- Total selenium WQG is exceeded in both summer and winter months during Post-closure for both alternative cases by up to 2.7 times (highest total Selenium concentrations found in Alt Case 5). The long-term winter and summer results in 2100 are below the guideline.
- The nitrite WQG is exceeded in winter months by up to 2.9 times the guideline with some exceedances in summer months (both in Alt Cases 2 and 5, with highest concentrations found in Alt Case 5).
- The dissolved cobalt WQG is exceeded up to 70 times for alternative case 5, and up to 4 times for alternative case 2. No exceedances occur in summer. Long-term average winter and summer results are below the WQG.

Change in water quality in Four Creek was also evaluated for selected additional parameters:

- Stream temperature, TSS, and turbidity is expected to remain unchanged, as there will be no Project discharge to this creek. Suspended particles are settled in the management and control ponds, and are expected to be removed during groundwater transport.
- Maximum TDS and conductivity were above the 95th percentile baseline concentration for TDS and conductivity during Post-closure in the Project Case, but the change was within 10% of the baseline value. Long-term average concentrations of these parameters are within the natural variability of baseline monitoring data (i.e., less than 95th percentile baseline concentration) through 2100.
- No change is expected for in-stream pH, alkalinity, and PAH concentration.

5.1.2 Tenas Creek

Like Four Creek, changes to Tenas Creek streamflow are governed by the following Project interactions:

- Project footprint, which occupies up to 7% of the existing Tenas Creek catchment and reduces the streamflow over baseline conditions in portions of the creek that are downstream of the Project. The change ins most apparent during open-water season months when runoff rates govern streamflow.
- Groundwater table drawdown from open pit mining, which will reduce the baseflow contributions to Tenas Creek in prediction nodes adjacent to the open pit by up to 6%.
- Management Pond seepage may be minimized through implementation of liners; however, some seepage is expected to reach Tenas Creek, resulting in net increase in baseflow rates towards the end of mining and into Post-closure as well as higher water quality concentrations for constituents of concern.

Streamflow in segments of Tenas Creek will be reduced by less than 10%. The sensitivity case for groundwater seepage rates presented in Alternative Assessment Case 1 could further reduce baseflow during winter at prediction nodes directly downstream of the open pit.

Baseline water quality monitoring show that exceedances have occurred historically in Tenas Creek for total aluminum, based on 50th and 95th percentile values from baseline data calculated for the stream.

Groundwater seepage from the West and North Management Ponds in the Post-closure period results in higher concentrations of modelled parameters downstream of the Project, but no exceedances of WQG was shown to occur for the Project Case. However, Alternative case 2 (high source term) showed exceedance for the following parameter:

- The total selenium WQG is exceeded at downstream prediction nodes WQS22 and WQS04 in winter months during Post-closure by up to 1.5 times the guideline.
- The dissolved cobalt WQG is exceeded at downstream prediction nodes WQS22 and WQS04 in winter months during Post-closure up to 1.8 times the guideline.

Change in water quality in Tenas Creek was also evaluated for selected additional parameters:

- Stream temperature, TSS and turbidity is expected to remain unchanged, as there will be no Project discharge to this creek. Suspended particles are settled in the management and control ponds and are expected to be removed during groundwater transport.
- Maximum TDS and conductivity were above the 95th percentile baseline concentration for TDS and conductivity during Post-closure in the Project Case, however results were within 10% of the natural variability. Long-term average concentrations of these parameters are within the natural variability of baseline monitoring data (i.e., within 10% of the 95th percentile baseline concentration) through 2100.
- No change is expected for in-stream pH, alkalinity, and PAH concentration.

5.1.3 Goathorn Creek

The Project interacts with Goathorn Creek through surface discharge, open pit mining and Management Pond seepage, however based on the larger catchment area, the change to streamflow is less than in Four Creek and Tenas Creek.

- Groundwater table drawdown from open pit mining will reduce the baseflow contributions in prediction nodes upstream and directly downstream of the open pit. This includes WQS13 and WQS06US. The change relative to baseline is expected to be less than 3%.
- Seepage from Management Ponds counters the drawdown from open pit mining, however an overall reduction in winter baseflow is still expected. Seepage will increase overall water quality concentrations. This does not cause new exceedances in the stream.
- Project discharge from the Tenas Control Pond in Operations and the North Management Pond at closure will change streamflow downstream in Goathorn Creek at WQSEA1, WQS06 and WQS05. Despite diverting water from Tenas Creek to Goathorn, streamflow is lower in some open water months because of evaporative and seepage losses from the Project facilities. Streamflow increases at closure, when vegetated covers are in-place on Management Ponds. The Tenas Control Pond discharges in May through October. Baseline data indicate freshet usually occurs in April. During Operations in April, streamflow at WQSEA1 decreases. After the Tenas Control Pond is decommissioned, the NMP will discharge by gravity to a tributary of Goathorn Creek, which increases discharge in April after closure.

- Additional withdrawal from Goathorn Creek during Operations has been included in model results for up to 2.5% of baseline flows. This water is not used by the Project (i.e., water covers do not depend on this flow rate), and it is included as contingency source only.
- An increase in streamflow from consecutive wet years tested in Alternative Assessment Case 4 and Case 7 could result in a net increase of up to 10% in monthly average streamflow at downstream prediction nodes.

Baseline water quality monitoring show exceedances in Goathorn Creek for total aluminum, and dissolved copper based on 50th and 95th percentile values from baseline data calculated for the stream. Exceedance of water quality guideline expected to occur for the following parameters, in Operations and in Closure, therefore not driven by Project discharge under the Project Case results:

- Exceedances of the dissolved copper WQG occur in winter and summer during the operation and Post-closure phases in the Project Case, but results are within the natural variability of baseline monitoring data (i.e., less than the 95th percentile from baseline datasets). Because these exceedances are driven by naturally elevated concentrations of dissolved copper in the background, the concentrations do not decrease over time.

While no other exceedances were recorded for the Project Case, Alternative Case 2 had exceedances for the following parameters:

- Exceedances for total selenium by up to 1.5 times the WQG, occurring only in Closure during the winter months. These exceedances are below the WQG by 2100.
- Exceedances for dissolved cobalt by up to 1.5 times the WQG, occurring in Operations during the monthly maximum summer months, which corresponds to the higher discharge rates when EMP overflows in 2030. This likely could be mitigated through lower discharge in the Creek.
- Exceedances for dissolved cobalt by up to 1.1 times the WQG, occurring in Closure only in WQS05 during the monthly maximum winter months, which corresponds to seepage from the Project reaching the Creek in Post-closure. These exceedances occur for less than 10 year in the model results.

Both Alternative Case 7 and Alternative Case 4, which produces increased discharge from the Project did not record any additional exceedances in Operations or Closure.

Change in water quality in Goathorn Creek was also evaluated for selected additional parameters:

- Due to Project discharge, maximum increase in stream temperature was estimated to be 0.4 °C during operation and 1.4 °C in Post-closure. These changes are within natural variability compared to baseline stream temperature monitoring.
- TSS and turbidity levels are expected to increase due to discharge from Tenas Control Pond and North Management Pond particularly, however results are within the natural variability of baseline monitoring data (i.e., less than 95th percentile baseline concentration).
- Maximum TDS and conductivity were above the 95th percentile baseline value by more than 10% during Post-Closure in the Project Case. This is likely driven by discharge from North Management

Pond during low flow months, which likely could be mitigated based on learnings through Operations.

- No change is expected for in-stream pH, alkalinity, and PAH concentration.

Short term elevated concentrations can be prevented by controlled discharge from the ponds and active monitoring of downstream flow conditions and pond water quality.

5.1.4 Telkwa River

Minor increases in winter flows and decreases in open water season flows could occur during Operations at Telkwa River node WQS09, downstream of the confluence with Goathorn Creek. The reduction in open water season flows results from evaporative losses from the Management Ponds and end pit lake. Decreased flow in winter is from less groundwater discharge to the streams. Over time, the water levels in the Management Ponds result in a small (~1%) increase in baseflow conditions (Appendix F, Table F-3).

Baseline water quality exceedances have occurred in Telkwa River for total aluminum, dissolved copper, and total iron. Model results show exceedances of the total aluminum WQG in summer during the operation and Post-closure phases in the Project Case. However, the results are less than the natural variability recorded in the baseline monitoring data (i.e. less than the 95th percentile from baseline datasets). Exceedances of the WQG of dissolved copper are experienced in summer throughout operation phase only but results are less than the 50th percentile from baseline data.

No additional water quality exceedances are expected beyond what has been experienced historically based on Project Case conditions or Alternative Assessment cases.

5.1.5 Bulkley River

The Bulkley River at node WQS11 receives Project discharge from the Rail Infrastructure Sedimentation Pond. The change to MAD is less than a 0.01% increase from the higher runoff coefficient for the stockpile area compared to natural conditions.

WQS12 is located on Bulkley River downstream of the Telkwa River confluence. Changes described for the Telkwa River propagate into the Bulkley River but have a much smaller effect in relation to baseline, with a maximum percent reduction of less than 0.1%.

Baseline water quality monitoring show that exceedances have occurred in the Bulkley River for total aluminum, dissolved copper, and total iron. Model results show no during the operation and Post-closure phases in the Project Case.

No additional water quality exceedances are expected beyond what has been experienced historically. This is consistent for the Project Case as well as the Alternative Assessment cases.

5.2 Summary in Context with Regional Study Area

5.2.1 Change to Streamflow

Table 5-1 and Table 5-2 summarize the change to mean annual discharge and seasonal flow distribution, respectively, with the affected streams' watershed, the LSA and the RSA. Results are based on the Project Case.

The change to mean annual discharge and the seasonal streamflow distribution reflect the area where the annual average flows or the monthly average flows are either reduced by more than 10% or increased by more than 30% relative to pre-mining conditions. The effects are local to Four Creek, however in the case of seasonal flow distribution, the effect propagates further upstream and includes node WQS03.

Table 5-1: Summary of Change to Mean Annual Discharge for Project Case

Stream	Four Creek
Prediction nodes Affected	WQS20, WQS21, WQS03DS
Project Stage	Operation, Post-Closure
Affected Area [km^2]	7.6
Total Stream Area [km^2]	11.0

Notes:

1. LSA is 208.3 km^2

2. RSA is 1430 km^2

High flows are expected to be reduced over baseline conditions for prediction nodes with reduced catchment areas. For the segment of Four Creek with an increase in catchment area, downstream of the diversion channel, an engineering control structure will limit the discharge during extreme events, sending excess water to the East Management Pond. Similarly, the Tenas Control Pond will have the ability to control high flood events by having the capacity to attenuate flows up to the 1 in 10-year flood event. As a result, the change in high flows is expected to be minimal.

Low flows are expected to be reduced in Operations along sections of Tenas and Four creeks from the drawdown of the groundwater table around the open pit. Extreme low flows will be similarly affected. The rate of change to low flows is captured in the discussion of winter flow in the seasonal streamflow distribution results (Table 5-2).

5.2.2 Change to Stream Water Quality

Table 5-3 summarizes the change to surface water quality under the Project Case in context within the affected streams' watershed, the LSA and the RSA. The Project Case represents the expected outcomes based on reasonably conservative assumptions and Project characterization and is used to support the EA.

According to the definitions in the EA, affected areas are identified where a water quality model result exceeds both the relevant WQG and the variability in the background water quality (95th percentile). The only parameter in the model that exceeds both background water quality and the WQG is dissolved cobalt in Four Creek. In the case of specific conductance and total dissolved solids, where no WQG is available, the model results show that only Goathorn Creek is expected to be affected, with model results greater than 10% above the 95th percentile background water quality in Post-Closure.

As a result, only Four and Goathorn creeks are presented as being affected by the Project (Table 5-3).

While model results show exceedances for total aluminum and dissolved copper in Goathorn Creek and Telkwa River, these results are driven by the elevated concentrations in the background data. The incremental increase because of the Project is minimal (<1%), as described in Section 4.4.1. Therefore, these areas are not presented as being affected by the Project.

Table 5-3: Summary of Change to Water Quality for Project Case

Stream	Four Creek	Goathorn Creek	Total Affected
Prediction nodes Affected	WQS03DS	WQSEA1, WQS06, WQS05	
Parameters with Exceedances of water quality guidelines (1)	Dissolved Cobalt	N/A	
Additional Parameters greater than baseline (2)	N/A	TDS, SC	
Project Stage	Post-Closure	Post-Closure	Post-Closure
Affected Area [km^2]	5.7	6.7	12.4
Total Stream Area [km^2]	11.0	195	206
% of Total Stream Area Affected by Project	52%	3%	6.0%
% of LSA Affected by Project (3)	3%	3.2%	6.0%
% of RSA Affected by Project (4)	0.4%	0.5%	0.9%

Notes:

1. Exceedances occur for a minimum of 1-month under Project Case
2. Exceedances are in relation to the 95th percentile of baseline monitoring data and occur for a minimum of 1-month under Project Case
3. LSA is 208.3 km^2
4. RSA is 1430 km^2

The affected area in Four Creek represents the catchment area between nodes WQS20 and WQS03DS. This area is expected to be significantly lower based on the perched nature of the majority of the creek (SLR 2025). Due to the uncertainty associated with the extents of the perched vs. unperched creek segments, the full area between these nodes was carried forward into the EA.

6 Conclusions and Recommendations

A water and load balance model has been developed based on Feasibility-level Project characterization, including hydrology, geochemical source terms, groundwater modeling, and the detailed mine plan and associated water management systems. The model produced time series of monthly flows and water quality within the Project infrastructure and in the receiving environment throughout the life of mine to 2100.

Within the Project facilities, the model demonstrates the minimum water cover target of 0.5m within 6 months of PAG rock placement can be maintained in all Management Ponds during Operations and a water cover target of 1.5 m for Post-closure. Temporary water cover reductions may be experienced under extreme dry or highly constrained periods, however sufficient water is expected to be available within other facilities (Tenas Control Pond, other Management Ponds or Goathorn Creek) to manage the water covers and PAG rock is subsequently covered with 0.5 m of water within 6-months of placement.

The Project has the potential to interact with receiving environment water quantity and water quality via four primary mechanisms:

- Reduction of natural catchment area, resulting in an equal reduction to streamflow over baseline conditions.
- Change in winter groundwater seepage (baseflow) to streams because of open pit mining (groundwater drawdown) and mounding of groundwater from increased head in Management Ponds and the Tenas Control Pond (increased seepage rates).
- Seepage from the West Management Ponds, the Tenas Control Pond will have elevated concentrations relative to baseline conditions, resulting in potential exceedances of WQG in the receiving environment for dissolved cobalt.
- Project discharge to the downstream environment may result in changes to streamflow and water quality.

Discharging facilities (Rail Infrastructure Sedimentation Pond, Tenas Control Pond and North Management Pond) have effluent concentrations that are higher than the WQGs for the following parameters of concerns in the end-of-pipe effluent: total selenium , nitrate-nitrogen, nitrite-nitrogen, sulfate, total aluminum, dissolved cadmium, dissolved cobalt, dissolved copper, total iron, total molybdenum, dissolved nickel, total thallium and dissolved zinc during active discharge periods under Project Case conditions, and only resulted in one exceedance from the Project discharge once in the stream, only in Closure in Four Creek for a few years (4 consecutive years). The high source term case (Alternative Assessment Case 2) may require additional mitigation measures to manage selenium concentrations for short periods of time in the Tenas Control Pond/North Management Pond.

Stream results are screened against applicable guidance to evaluate the change resulting from the Project on the environment, which include:

- Whether streamflow is increased by more than 30% or decreased by more than 10% relative to baseline conditions.

- Whether seasonal flow distribution changes.
- Changes to high and low flows.
- Whether stream water quality exceeds relevant water quality guidelines when exceedances did not occur historically (within natural variability).

Changes to streamflow are summarized as follows:

- Change in streamflow is expected to occur in Four Creek, from an increase in flow from diversion channels and a reduction in flow from groundwater drawdown and catchment reductions. The change relative to baseline is greater than 10% reduction to mean annual discharge, with higher changes monthly.
- Tenas Creek will experience months, predominantly in April and August, with up to 10% reduction to baseline streamflow, however the change to mean annual discharge is less than 10% throughout Operations and closure periods.
- Goathorn Creek flows are expected to be reduced by up to 6% in low flow months in Operations, while increasing by up to 8% during freshet. The overall change to mean annual discharge is a reduction of 4% in Operations and 1% Post-closure.
- Both Telkwa and Bulkley Rivers experience less than 1% change relative to baseline conditions due to the relatively small Project footprint with respect to the total catchment areas of each river.

WQG exceedances is expected under Project Case conditions for dissolved cobalt in Four Creek for a period of four years, as well as for dissolved copper and total aluminum in Goathorn Creek and Telkwa River, which are naturally elevated in the background concentrations. The baseline water quality records already show exceedances for these parameters as part of the natural variability of the stream.

Elevated levels of TDS and EC are also expected in Tenas, Four and Goathorn Creeks downstream of the Project because of seepage from management ponds and discharge from the Project. Results in Tenas and Four creeks are within 10% of the 95th percentile from baseline data in each stream, however the results in Goathorn Creek are up to 30% increase relative to the 95th percentile baseline data. This effect occurs in the Post-Closure Phase only.

The change to both stream water quantity and quality were further evaluated in terms of the affected area within the spatial boundaries of the Project, including the local stream watersheds, the LSA and the RSA.

- In terms of water quality, the only modelled prediction node that is expected to experience long-term exceedances of the WQGs and the 95th percentile of background data is in Four Creek at node WQS03DS for dissolved cobalt for a period of four years. In addition, the modelled TDS and SC concentrations are expected to be above the 95th percentile of background monitoring by more than 10% in Goathorn Creek during Post-Closure. The affected area includes the lower portions of Four and Goathorn creeks, which is an area equal to 12.4 km^2. This affected area represents approximately 6% of the LSA and less than 1% of the RSA.
- In terms of water quantity, the modelled prediction nodes that experience a change to mean annual discharge greater than 10% reduction or 30% increase include WQS21, WQS20 and WQ03DS, which encompasses an area equal to 7.6 km^2. This affected area represents approximately 3.6% of the LSA and 0.5% of the RSA.

The results from this study and report will be used as part of the EA Application.

Recommendations:

- Continue to collect water quality and quantity data throughout project implementation.
- Model to be reviewed and updated as-needed annually with results from monitoring.
- No additional strategies to reduce concentrations in Management Ponds and Control Ponds are recommended at this point as there are no exceedances resulting from the Project. However, contingencies measures are put in place to mitigate any deviations from these results, as recommended in the conclusions of the BAT assessment report (SRK 2025a). Contingencies include in-situ Gravel Bed reactors treatment in Management Ponds and Active treatment post Tenas Control Pond.

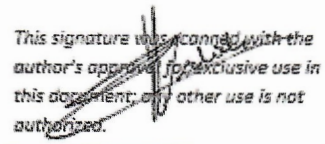
6.1 Risks and Limitations and Opportunities

Risks and limitations of the model are summarized below based on assumptions and data incorporated into the model:

- The Project area rainfall-runoff model simulates an earlier freshet onset than the Goathorn Creek rainfall-runoff model, based on the median elevation and climate correction factors (Section 3.1.7). The modelled increase over pre-mining conditions during freshet at closure may not be as prominent as the model estimates since the rock covers will likely remain frozen for a longer period once vegetation is established due to the relatively flat slopes in comparison to the natural topography.
- Rainfall-runoff models are developed based on constant monthly runoff coefficients, calibrated from historical records. Changes to the timing of spring freshet or other annual hydrologic phenomenon which may be expected with climate change projections could result in changes to the monthly runoff rates. These types of effects are not currently captured in the water balance model. Additional climate change -related risks include:
  - Increased occurrence of wildfires which could result in higher runoff during rainfall and snowmelt events (because of reduction of vegetative cover, hydrophobic soils, etc.), and could result in greater sediment loading to the receiving environment(s),
  - Changes in hydrograph seasonality, which could result in shifting low flows to the summer months which coincide with planned discharges and could reduce dilution / assimilation capacity in the receiving environment(s), and
  - Altered interactions with natural groundwater system, which could result in reduced baseflow contributions and could reduce dilution/ assimilation capacity in the receiving environment(s) during winter or summer months.
- Ongoing collection of hydrometric and meteorological data will be completed through the subsequent Project design phases. The Project climatic records, as well as the calibrated rainfall-runoff models should be revisited based on additional data collected on-site, specifically to improve the characterization of Tenas Creek and Four Creek, which have limited records.

- The water balance for the historic years was calibrated based on measured site data. Any error in this data collection would directly affect the reliability of the model calibration.
- Solubility limits were not universally applied in the model. Consequently, some parameters may precipitate prior to reaching the modelled concentrations.
- The model treated all reservoirs as perfectly mixed containers. This mixing occurred instantaneously at every time step and may not be reflective of actual conditions.
- Groundwater and impacted seepage flows are based on hydrogeologic models which are based on a limited hydrogeologic dataset.
- Uncertainty in MAP and evaporation predictions.
- Additional limitations of input data are discussed in topic-specific reports.

Opportunities:



- The primary driver of increased water quality concentrations in the receiving environment is seepage from Management Ponds and the Tenas Control Pond. The model assumes that 100% of the mass of constituents leaving the Management Ponds via seepage eventually reaches the streams, without any attenuation. Constituents transported through groundwater pathways may be attenuated through dispersion and advection mechanisms, which could ultimately improve the water quality discharging downstream. In addition, the extended period between when seepage leaves the facility and discharges to surface water provides a significant time for intervention or mitigation measures to be employed. Active groundwater monitoring will be incorporated into the monitoring plans to capture the rate and concentrations of migration of the seepage plume.
- Increase efficiency of liners in Management Ponds and the Tenas Control Pond in terms of minimizing seepage rates could be investigated to reduce the amount of load entering the receiving environment via groundwater pathways (SRK 2025b).
- Active monitoring of pond water quality in tandem with in-stream water quality along with streamflow is expected to enable control of pond discharges to reduce the occurrence of exceedances in Goathorn Creek during Operations.

Contingencies (SRK 2025a and b):

- Organic carbon addition to the covered management ponds Post-closure to create reducing conditions to decrease selenium mobility using Gravel Bed reactor within the management ponds.
- Active water treatment plant of water collected in management and control ponds.
- Increasing water stored through low flow period in the summer and discharge more during freshet when dilution capacity is greater.
- Utilize the 2.5% water withdrawal from Goathorn Creek in Project's overall water management plan.
- Evaluate the construction schedule of the management ponds and potentially build the dams earlier to create additional storage before PAG placement is required.

Subject:	Prediction Node Streamflow Assessment to Support Water and Load Balance Model		

1 Introduction

An Environmental Assessment (EA) is being completed for the Tenas Project (the "Project") near Smithers B.C, which includes a water and load balance model to evaluate impacts to downstream creeks and rivers. Prediction nodes included in the model include locations along Tenas Creek, Four Creek, Goathorn Creek, Telkwa River and Bulkley River, as defined in the Tenas Project Water and Load Balance Report (SRK 2021a).

The following memorandum presents the methodology for evaluating streamflow within each watercourse and at each prediction node. Results are incorporated into the water and load balance model to develop water quality and quantity estimates pre- and post-mining.

1.1 Supporting Information

1.1.1 Climate Data

A detailed meteorological analysis was presented in the 2021 Hydrometeorological Baseline and Model Development Report (SRK Consulting, 2021b). The Project climate timeseries described in this work were used as an input for this analysis.

1.1.2 Regional Hydrometric Data

Water Survey of Canada (WSC) is the national authority responsible for the collection, interpretation and dissemination of standardized water resource data in Canada. Four WSC regional stations maintain long term records on streams and locations relevant to the Project as illustrated on Figure 1-1. These stations have more than 10 years of data and catchment areas ranging between 125 km^2 to 8940 km^2. Table 1-1 shows a summary of the metadata for these stations.

Table 1-1: Summary of Regional Hydrometric Stations

Station ID	Station Name	Longitude	Latitude	Area (km^2)	First Year	Last Year
08EE008	GOATHORN CREEK NEAR TELKWA	54.65	-127.12	125	1960	2016
08EE020	TELKWA RIVER BELOW TSAI CREEK	54.61	-127.50	367	1975	2018
08EE004	BULKLEY RIVER AT QUICK	54.62	-126.90	7340	1930	2018
08EE005	BULKLEY RIVER NEAR SMITHERS	54.77	-127.13	8940	1945	2018

Source: compiled in text from R code \\srk.ad\dfs\na\van\Projects\01_SITES\Telkwa Coal\1CT027.002 2017-18 permitting Support (Phase 2)\0200_SurfaceWater\Hydrology\R files\Flows_update_rev06.Rmd

1.1.3 Project Hydrometric Data

Four hydrometric stations were installed at the Project in 2017.

- Tenas-Hydro was established on Tenas Creek upstream of the confluence with Goathorn.
- Goathorn-Hydro was established on Goathorn Creek upstream of the Goathorn-Tenas confluence.
- Telkwa-Hydro was established on the Telkwa River upstream of the confluence with Goathorn Creek.
- Four-Hydro was established on Four Creek in April 2020, upstream of the confluence with Goathorn Creek.

Table 1-2 summarizes the metadata for these stations, and their location and catchment delineations are shown in Figure 1-1. The Goathorn-Hydro station is located at the same location as the WSC Goathorn station (08EE008).

Table 1-2: Summary of Local Hydrometric Stations

Station Name	Longitude	Latitude	Area (km^2)	Average Catchment Elevation (masl)	Start of Record
Four Hydro	54.62	-127.14	11.0	985	April 2020
Tenas-Hydro	54.62	-127.19	47.4	1181	May 2017
Goathorn-Hydro	54.65	-127.12	121.6	1243	May 2017
Telkwa-Hydro	54.65	-127.17	966.9	1243	May 2017

Source: compiled in text from R code \\srk.ad\dfs\na\van\Projects\01_SITES\Telkwa Coal\1CT027.002 2017-18 permitting Support (Phase 2)\0200_SurfaceWater\Hydrology\R files\Flows_update_rev06.Rmd

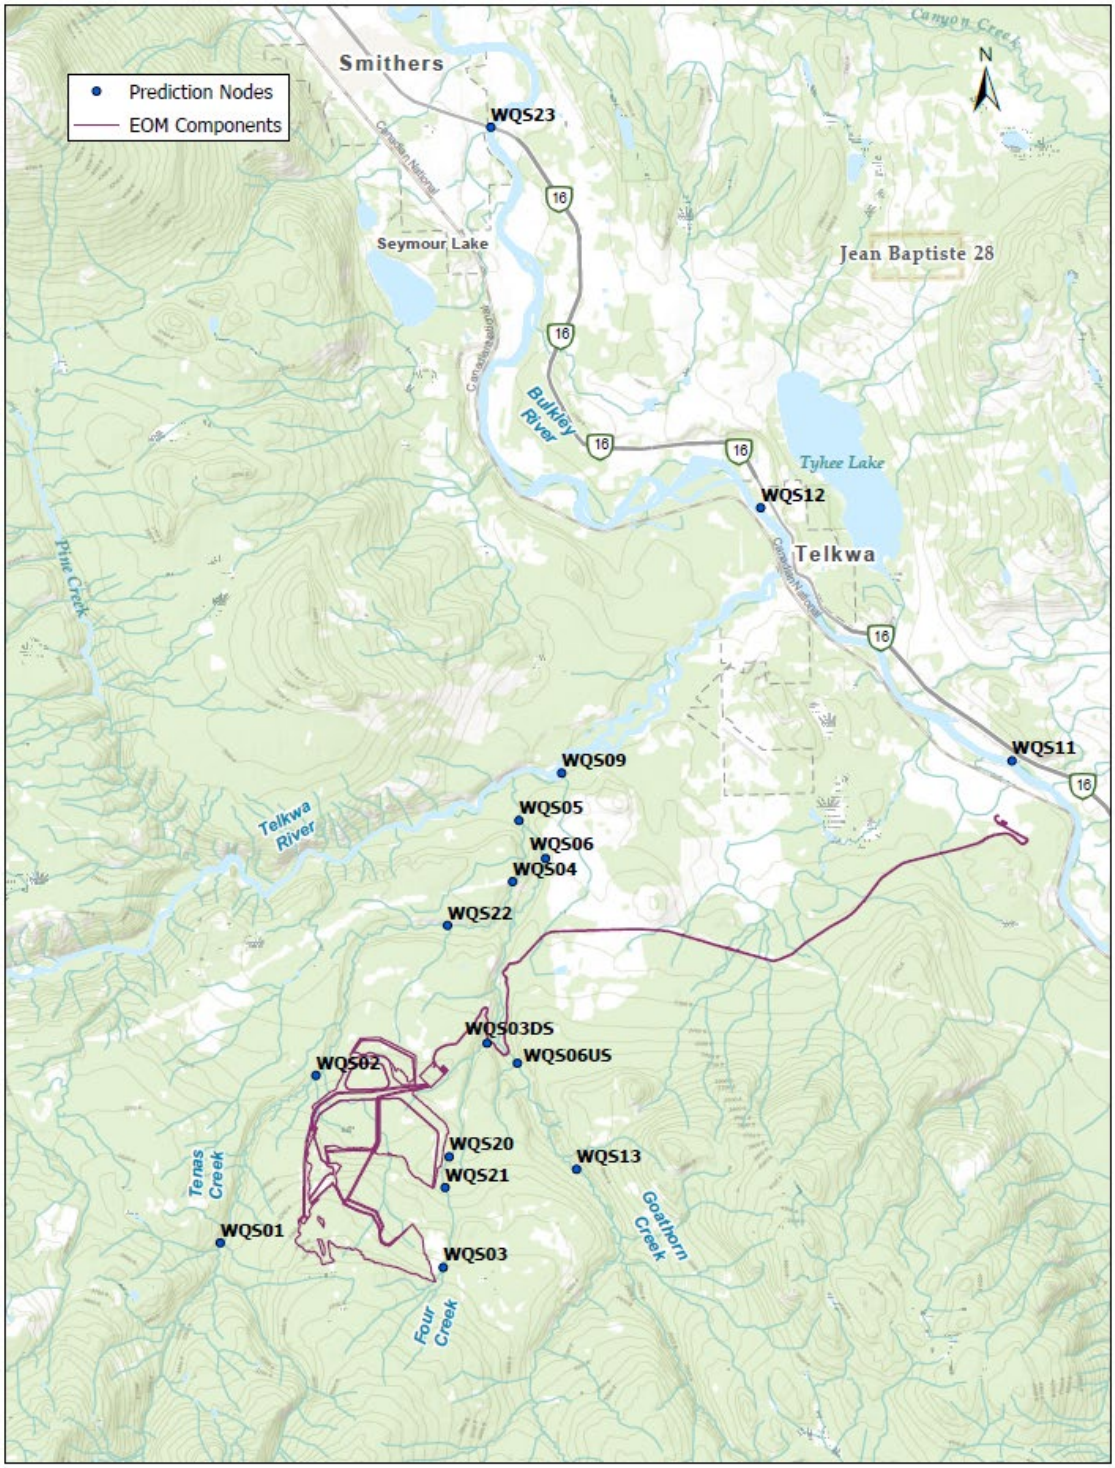
Project records and regional records were compared and patched together as described in SRK 2021b to provide the long-term flow timeseries that were used in this analysis.

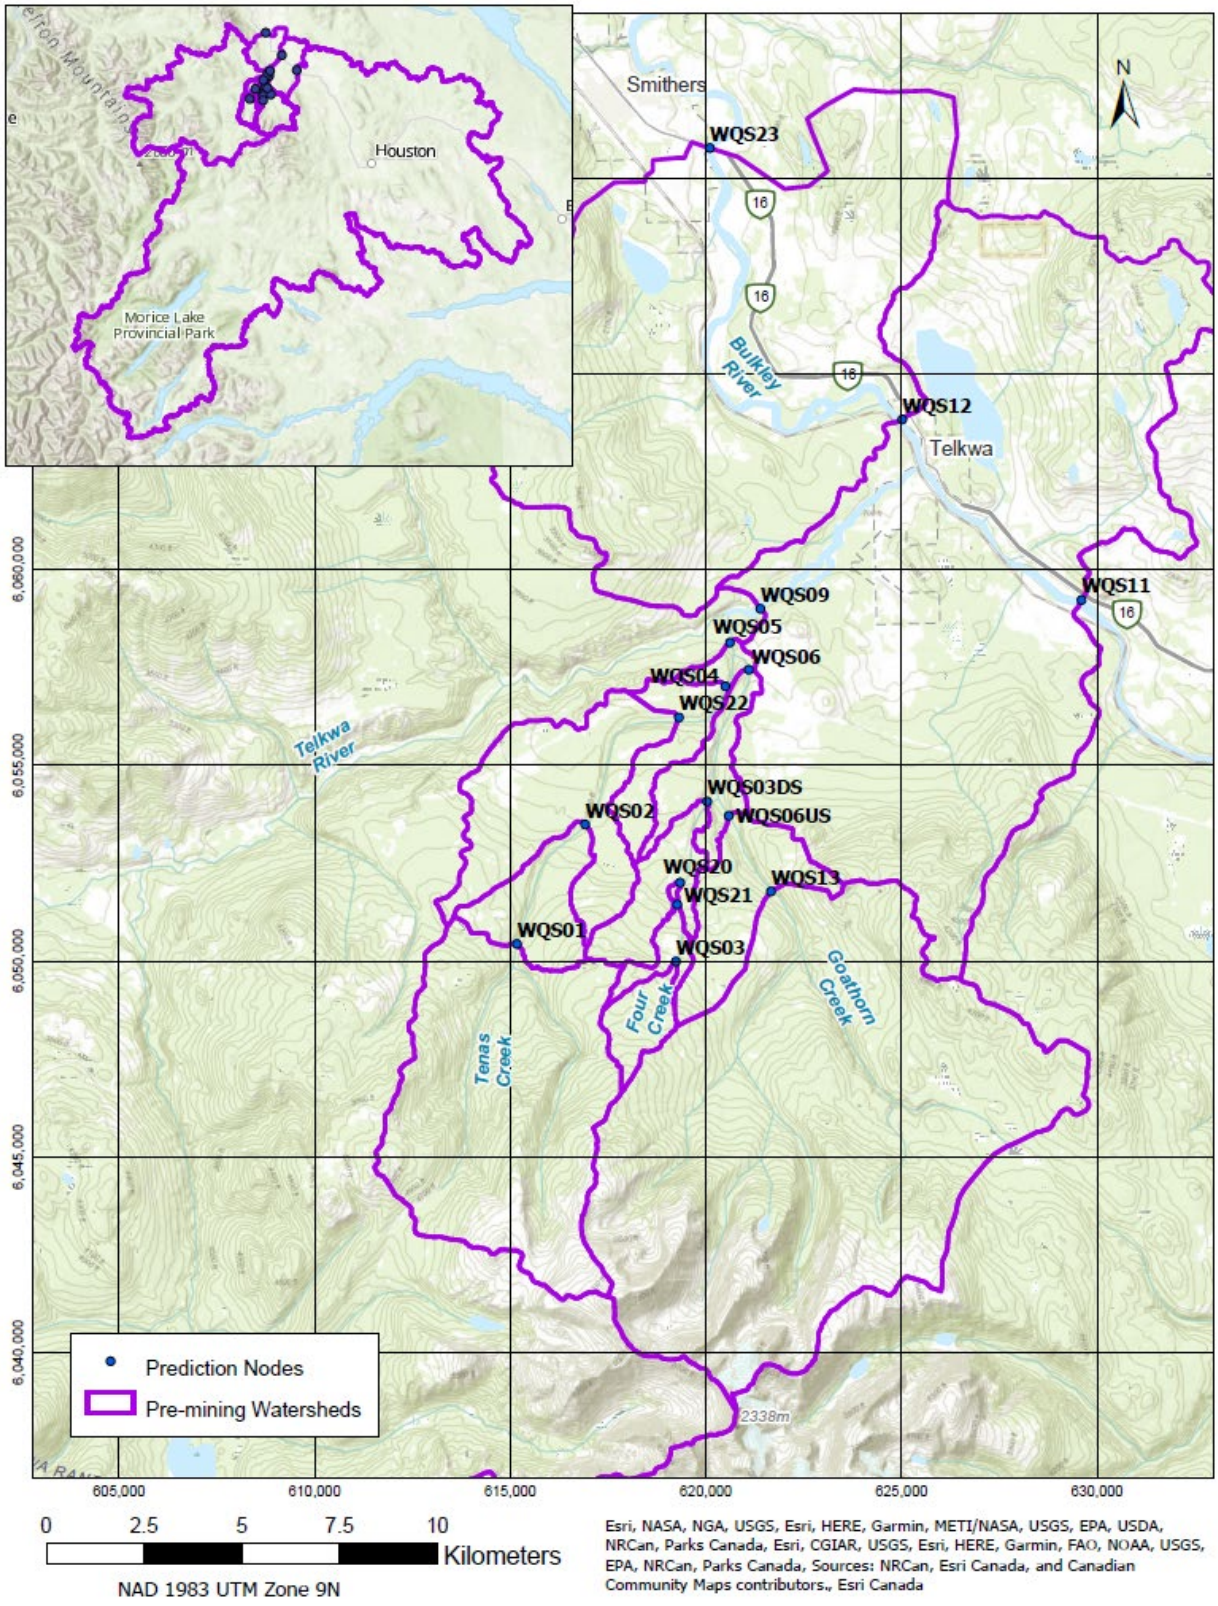
2 Location of Prediction Nodes



A total of 16 in-stream prediction nodes were selected for the water and load balance to evaluate impacts from the Project, including nodes along Tenas Creek, Four Creek, Goathorn Creek, Telkwa River and Bulkley River.

Project infrastructure will result in changes to the catchment area contributing to each prediction node. Table 2-1 summarises the prediction node coordinates, as well as associated catchment area pre- and post-mining. Node locations are presented in Figure 2-1. Figure 2-2 and Figure 2-3, present the catchment area for each node under pre- and post-mining conditions, respectively.

Table 2-1: Receiving Environment Prediction Nodes, from Upstream to Downstream



Prediction Node	Stream and Description	Coordinates NAD 1983 UTM Zone 9N (m)		Total Catchment Area (km^2)	
		Easting	Northing	Pre-mining	Post-mining
WQS01	Tenas Creek, upstream of Project	615,171	6,050,438	40.7	40.7
WQS02	Tenas Creek, adjacent to Project	616,914	6,053,490	47.6	47.0
WQS22	Tenas Creek, upstream of Project discharge (Unnamed Stream below Tenas Pond)	619313	6056222	65.7	61.9
WQS04	Tenas Creek, downstream of Project discharge (Unnamed Stream below Tenas Pond)	620,499	6,057,020	70.8	65.9
WQS03	Four Creek, upstream of Project	619,235	6,049,989	3.3	3.9
WQS21	Four Creek, upstream of East Management Pond	619269	6051446	5.2	4.9
WQS20	Four Creek, downstream of East Manageemnt Pond	619344	6052005	5.3	5.0
WQS03DS	Four Creek, downstream of Project, upstream of confluence with Goathorn Creek	620,034	6,054,076	10.9	6.9
WQS13	Goathorn Creek, upstream of Project	620,867	6,049,161	97.9	97.9
WQS06US	Goathorn Creek, upstream of Tenas Creek and Four Creek	620,587	6,053,711	107.1	107.1
WQS06	Goathorn Creek, upstream of Tenas Creek, downstream of Four Creek	621,100	6,057,441	123.5	119.1
WQS05	Goathorn Creek, downstream of Tenas Creek	620,615	6,058,133	195.5	186.2
WQS09	Telkwa River, downstream of Goathorn Creek	621,394	6,058,998	1198.9	1189.6

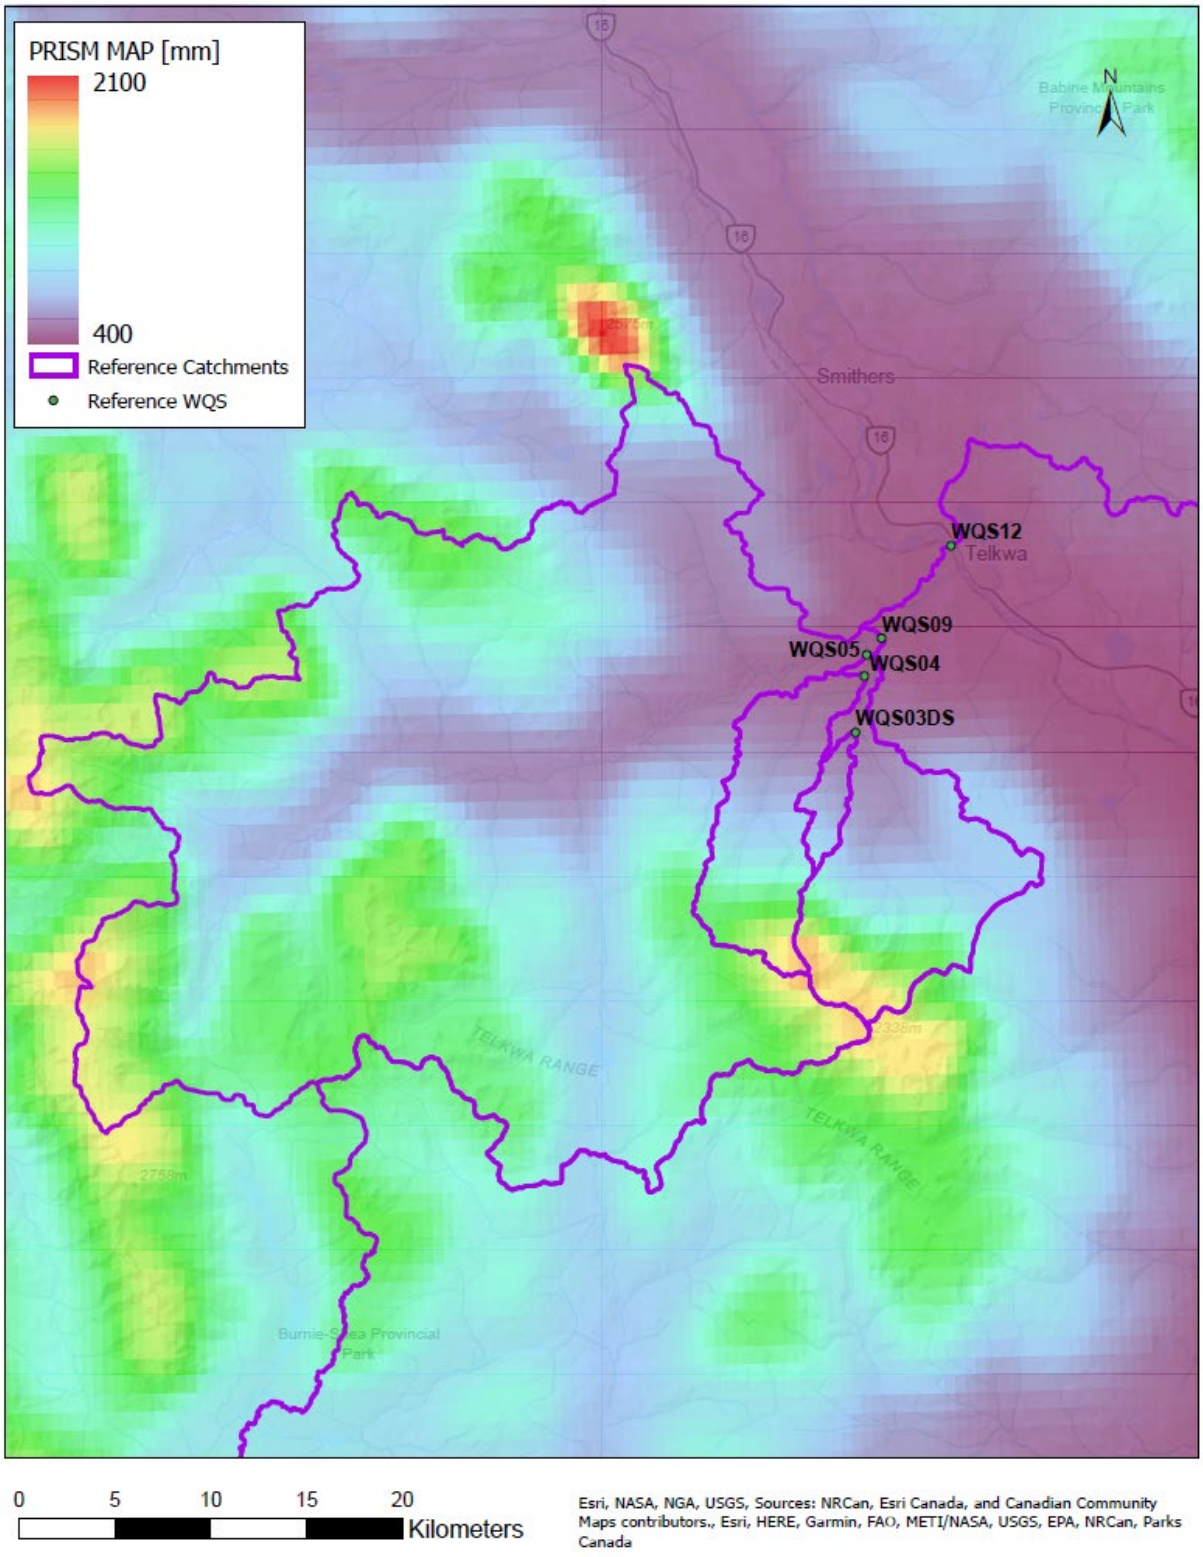
3 Streamflow Methodology

Correction factors were developed to apply the Project climate timeseries (SRK 2021b) for the catchments of Four Creek, Tenas Creek, Goathorn Creek, Telkwa River, and Bulkley River. These corrected climatic datasets, along with extended streamflow time series (SRK 2021b) were used to calibrate monthly runoff coefficients for each stream. Streamflow at each prediction node was then derived from the corresponding watershed climate timeseries and runoff calibration.

3.1 Climate Analysis

3.1.1 Methodology



To estimate the average climate conditions for the main Project watersheds accounting for orographic trends, climate correction factors were developed based on the PRISM reanalysis dataset, consistently with SRK 2021b.

PRISM is a climate-elevation regression model, used to generate a reanalysis dataset that provides precipitation and maximum and minimum temperature averages on a monthly timestep for the Pacific Region of Canada and the northwestern USA.

For each stream, a prediction node was selected to define a reference catchment area. PRISM datasets were then averaged over each of these catchments with an iterative raster calculation tool built in ArcGIS Pro (ESRI 2020) to obtain monthly averages for precipitation and temperature parameters for each area. For this analysis:

- Four Creek was represented by WQS03DS catchment area
- Tenas Creek was represented by WQS04 catchment area
- Goathorn Creek was represented by WQS05 catchment area
- Telkwa River was represented by WQS09 catchment area
- Bulkley River was represented by WQS12 catchment area

An illustration of a PRISM dataset and the reference catchments is presented in Figure 3-1.

Source: Z:\01_SITES\Telkwa Coal\1CT027.003_2020 EA Water Management\l040_AutoCAD\1.GIS\Telkwa_PRISMMAP.aprx

Figure 3-1: PRISM Mean Annual Precipitation (MAP) Dataset and Reference WQS and Catchments

The obtained monthly averages were then compared to the reference Project location PRISM results to obtain monthly correction coefficients for each climate parameter.

3.1.2 Climate correction coefficients

Monthly correction coefficients were calculated for the monthly maximum, average and minimum temperatures, as well as precipitation based on the ratio of Project records (SRK 2021b) and the PRISM datasets for each stream. These are presented for each watershed in Table 3-1, Table 3-2, Table 3-3 and Table 3-4 respectively.

Table 3-1: Monthly Precipitation Correction Factors

3.2 Runoff model

3.2.1 Methodology

Surface runoff is defined as the total amount of surface water discharged from a watershed and is frequently presented as the depth of water distributed evenly throughout the watershed area.

A daily rainfall-runoff model was generated to support streamflow estimations and to provide Project-specific runoff rates. The runoff model for the Project Area was developed using a

snowmelt model, a minimum baseflow function, a lag time, recession coefficient and monthly runoff coefficients for each of the main catchments. Monthly runoff coefficients were calibrated automatically within GoldSim by optimizing the Nash Sutcliffe Efficiency, based on the difference between observed and modelled daily flow. Observed flows, in this case, were the extended records for each of the local hydrometric stations, described in Section 1.1.3. The calibration is described in SRK 2021b.

Precipitation was converted to runoff using a two-step process. The first step converts precipitation to either rainfall or snowfall using the SNOW-17 snow accumulation and ablation model described in SRK 2021b. The output from the snowmelt model is a daily effective precipitation value, representing the sum of rainfall and snowmelt available for runoff.

The second step uses a function from the Snowmelt Runoff Model (SRM), a program and methodology designed to simulate and forecast daily streamflow in mountain basins (J. Martinec, 2008). Each day, water produced from snowmelt and rainfall is superimposed on the calculated recession flow and transformed into a daily discharge from the basin. The discharge is calculated as the minimum of baseflow or runoff from snowmelt and rainfall, according to Equation 1:

$$Q_{n+1} = minimum\ of \begin{cases} C \times P_{eff} \times \frac{A \times 10{,}000}{86{,}400} \times (1 - k_{n+1}) + Q_n \times k_{n+1} \\ B\,x\,A \end{cases} \quad \text{Eq [1]}$$

Where:

Q = average daily discharge [m^3/s]

C = monthly runoff coefficient expressing losses as a ratio (runoff/precipitation)

P_{eff} = Effective precipitation as the sum of snowmelt and rainfall

A = area of the basin [km^2]

k = recession coefficient indicating the decline of discharge in a period without snowmelt or rainfall, $k = \frac{Q_{m+1}}{Q_m}$ where m, m+1 are the sequence of days during a true recession flow period

n = sequence of days during the discharge computation period, also referred to as the lag time.

B = unit baseflow [m^3/s]

Calibration of recession coefficients, *k*, monthly runoff coefficients, *C*, and unit baseflow, *B*, were developed in GoldSim by optimizing the Nash Sutcliffe Efficiency based on the difference between observed and modelled daily discharge. A separate calibration model was prepared for Four Creek, Goathorn Creek, Telkwa River, Bulkley River, and Tenas Creek.

Long term daily flow records at each prediction node were calculated based on corresponding hydrometric station synthetic flow records, minimum unit baseflow values (SRK 2021b), n values and Equation (1).

3.2.2 Rainfall-Runoff Model Inputs

Table 3-3 presents the rainfall-runoff model parameters calibrated for each stream, also presented in SRK 2021b.

Table 3-5: Rainfall-Runoff Model Inputs

Location		Goathorn	Telkwa	Tenas	Bulkley	Four	Project
Minimum Unit Baseflow [L/s/km^2]		1.8	4.1	0.43	3.0	0.3	1.1

Parameters were assigned to each node as follows:

- Tenas Creek runoff coefficients were applied to all Tenas Creek nodes including WQS01, WQS02, WS22, WQS04, as well as nodes on Four Creek, due to a lack of continuous Four Creek flow data at this time of the study, including WQS03, WQS21, WQS20, WQS03DS.
- Goathorn Creek runoff coefficients were applied to all Goathorn nodes including WQS13, WQS06US, WQS06, WQS05.
- Telkwa River runoff coefficients were applied to WQS09.
- Bulkley River runoff coefficients were applied to WQS11, WQS12 and WQS23.

4 Summary

The water and load balance model, developed in support of the Telkwa Project EA, uses a daily precipitation and temperature record generated for the Project (SRK 2021b) to simulate water volumes within the Project facilities and in the receiving environment. In order to account for the range in topography, from the Telkwa River valley to the upper reaches of the Goathorn and Tenas Creek watersheds, correction factors are required to account for orographic gradients of temperature and precipitation. These correction factors were established based on a published climate-elevation regression model (PRISM), that provides precipitation and maximum and minimum temperature averages on a monthly timestep for the Pacific Region of Canada and the northwestern USA.

Monthly climate correction factors were developed for each of the five watercourses surrounding the Telkwa Project, including Four Creek, Tenas Creek, Goathorn Creek, Telkwa River and Bulkley River, based on the Project-specific records for daily maximum and minimum temperature, and daily precipitation. A calibrated rainfall-runoff model was developed for each stream using the adjusted climate parameters and a series of other runoff-related constants, as described in SRK 2021b. The model allows for estimation of streamflow based on precipitation and temperature inputs for the Project.

Note that based on the methodology applied, the low flow conditions are governed by a constant baseflow value which was selected to match the average low flow in summer and winter months. Extreme low flow conditions, such as the 7-day low flow event for a range of return periods, cannot be directly estimated from this method. Extreme low flows are calculated externally from this modeling approach and are presented in SRK 2021b and utilized in water balance modeling.

1 Introduction

Telkwa Mining Ltd (TML) submitted an Environmental Assessment Certificate (EAC), application for the Tenas Project, located at the Telkwa Property, near the town of Telkwa, British Columbia in May of 2022. In support of the EA application, SRK Consulting (Canada) Inc. (SRK) developed geochemical source terms (SRK 2022a) that formed the basis for evaluating changes to water quality in downstream receptors. The source terms were based on humidity cell testing (HCT) results. In parallel to the geochemical characterization testing program that was used to support the EAC application, TML initiated a field barrel testing program in late 2019. Release rates from the barrel testing program were compared to the scaled results that formed the basis of the source terms that were developed to support the EAC application. The outcomes indicated that the scaled HCT release rates were underestimated for some constituents while overestimated for others. Updated source terms were developed using the barrel release rates to reflect release rates more accurately under field conditions.

This report describes the conceptual models, methods and assumptions used to derive the site water quality model source term inputs based on the field barrel testing results. The site wide water quality model development and results are described in SRK (2024a).

2 Project Background

2.1 Geological Setting

2.1.1 Bedrock Geology

The Tenas Project is located within the northeast/southwest trending Skeena Arch, which separates Jurassic-age sedimentary rocks of the Bowser Basin in the north from the Jurassic to Cretaceous-age sedimentary rocks of the Nechako Basin to the south. The coal-bearing sedimentary rock sequence of the Project is associated with the Lower Cretaceous age Skeena Group, and unconformably overlies the Jurassic-age Hazelton volcanic group, which will be below the proposed pit limit. A simplified stratigraphic column of the Project's deposit is presented in Figure 2-1.

Jurassic Hazelton Volcanic Group

The volcanic rocks include andesite, trachyte, and basalt with associated tuffs and breccias.

Lower Cretaceous Skeena Group

The Lower Cretaceous Skeena Group includes marine and continental sediments interbedded with coal seams, often correlated over long lateral distances. It is subdivided into four units (Units I through IV) and a unit of undivided sediments overlying the four units (Figure 2-1).

The economic coal seams in the Tenas area are located within Coal Zone 1 of Unit I and include two seams: C seam and 1 seam (upper and lower). Coal Zones 2 through 10, located in Unit III (Figure 2-1), are absent from the Tenas area. Units I through IV are summarized below.

- The Unit I consists of more than 100 m of fine to coarse-grained cross-bedded sandstone, conglomerate, siltstone, mudstone, and coal (coal zone 1). Overall, Unit I fines upward, from primarily conglomerate and sandstone to almost entirely carbonaceous mudstone, seatearth and coal (1A to 1G). The conglomerate and sandstone were deposited in braided channels and bars, and mudstone accumulated in floodplains. Thin coal seams formed in poorly drained, peat-forming backswamps, and seatearths formed under leaching conditions in less submerged areas. With denudation of the volcanic source area, braid plains were abandoned and extensive low-energy, peat-forming swamps were established, resulting in the formation of thick coal seams in the upper part of the Unit.
- The Unit II separates coal zone 1 and coal zone 2. It consists of up to 140 m of primarily monotonous silty mudstone, occasionally interbedded with beds of chert-rich, micaceous, bioturbated or cross-bedded sandstone. The sediments were deposited in a deltaic/shallow marine environment following a regional marine transgression. The mudstone accumulated in bays, and the sandstones in distributary channels and mouthbars. Locally, thin discontinuous peat beds formed in salt marshes.
- Unit III comprises about 90 m of chert-rich, micaceous sandstone, siltstone, and mudstone, and up to nine coal zones (coal zones 2 through 10). The sandstone and mudstone were deposited and biogenically reworked in a tidal flat environment; siltstone accumulated in a restricted, nearshore marine environment. Peat accumulated in freshwater coastal marshes which periodically prograded over tidal flats.

- Unit IV consists of approximately 150 m of a laterally extensive, bright green, chert-rich, chloritic sandstone or siltstone bed at the base, overlain by massive grey silty mudstone like that of Unit II. The basal sandstone is a transgressive lag deposit, and silty mudstone, the predominant lithofacies, was deposited in a quiet, nearshore, shallow marine environment.

Intrusions

Tertiary and Cretaceous-age porphyritic dykes and sills commonly intrude this sequence, the most notable of which includes a Tertiary granodiorite intrusion located on the north side of the Telkwa River. These intrusions are not present in the Tenas area.

Geological Structures

The sedimentary sequence in the Tenas area is folded into a syncline in which the gently (typically 10 to 20°) northeast-dipping western limb of the syncline subcrops on the western side of the pit area, while the moderately (40 to 45°) southwest-dipping eastern limb subcrops on the eastern side of the pit. Faulting is generally near-vertical, and can be subdivided into two main groups, one which strikes approximately northwest/southeast and the other which strikes approximately northeast/southwest. A few east/west striking faults have also been interpreted.

The Goathorn area is located within an outlier of the Lower Cretaceous Skeena Group. The structural geology is somewhat more complex than the Tenas area and is characterized by a complex series of sub-parallel north-south trending reverse faults, and to a lesser extent east-west, trending normal faults.

Northeast striking faults are related to emplacement of the Bulkley intrusions in the Late Cretaceous.

2.1.2 Surficial Geology

The surficial geology in the Project area consists primarily of two types of deposits, glacial clay- or silt-rich till, and sand and glaciofluvial sand and gravel outwash. At upper elevations and south of the proposed pit, the terrain is mapped as having bedrock outcrops to a limited extent or thin mantles of clay- and silt-rich tills deposits, between 3 m and 10 m thick. North of the proposed pit and towards Tenas Creek and Goathorn Creek, drillholes report thin mantles of clay- and silt-rich tills deposits, between 3 m and 10 m thick underlain by a thick sand and gravel outwash deposit that can exceed 100 m.

Other types of deposits are present locally. Patches of glaciolacustrine deposits are scattered throughout the morainal landscape in low ridges and in depressions; the sediments comprise bedded and laminated mud, and minor sand and gravel (Clague 1984). Recent fluvial deposits form the narrow floodplains of Goathorn Creek and Tenas Creek, which are 40 m to 80 m deep incised into the subdued morainal landscape, and the wide floodplains of the Telkwa and Bulkley Rivers. The fluvial deposits range from extremely coarse, poorly sorted gravel on steep alluvial fans to moderately to well-sorted sand and mud on low-gradient floodplains (Clague 1984).

2.1.3 Material Zone Designations

Geochemical properties are stratigraphically constrained in coal deposits versus lithologically constrained. For example, the deposition environment of the Tenas Deposit includes marine and deltaic sedimentary sequences and rocks formed in these two different environments will be compositionally different. The deposit was demarcated into stratigraphic zones of sedimentary sequences between the mineable coal seams. The stratigraphic zones were further divided into additional zones if they had different distinct geochemical properties (e.g., Zone 1 and Zone 1a) or grouped if geochemical properties were similar between zones identified between coal seams (e.g., Zone 2 and Zone 3). The stratigraphic zones and classification of PAG and non-PAG based on an NPR of 2.0 identified for the Project are presented in Figure 2-2.

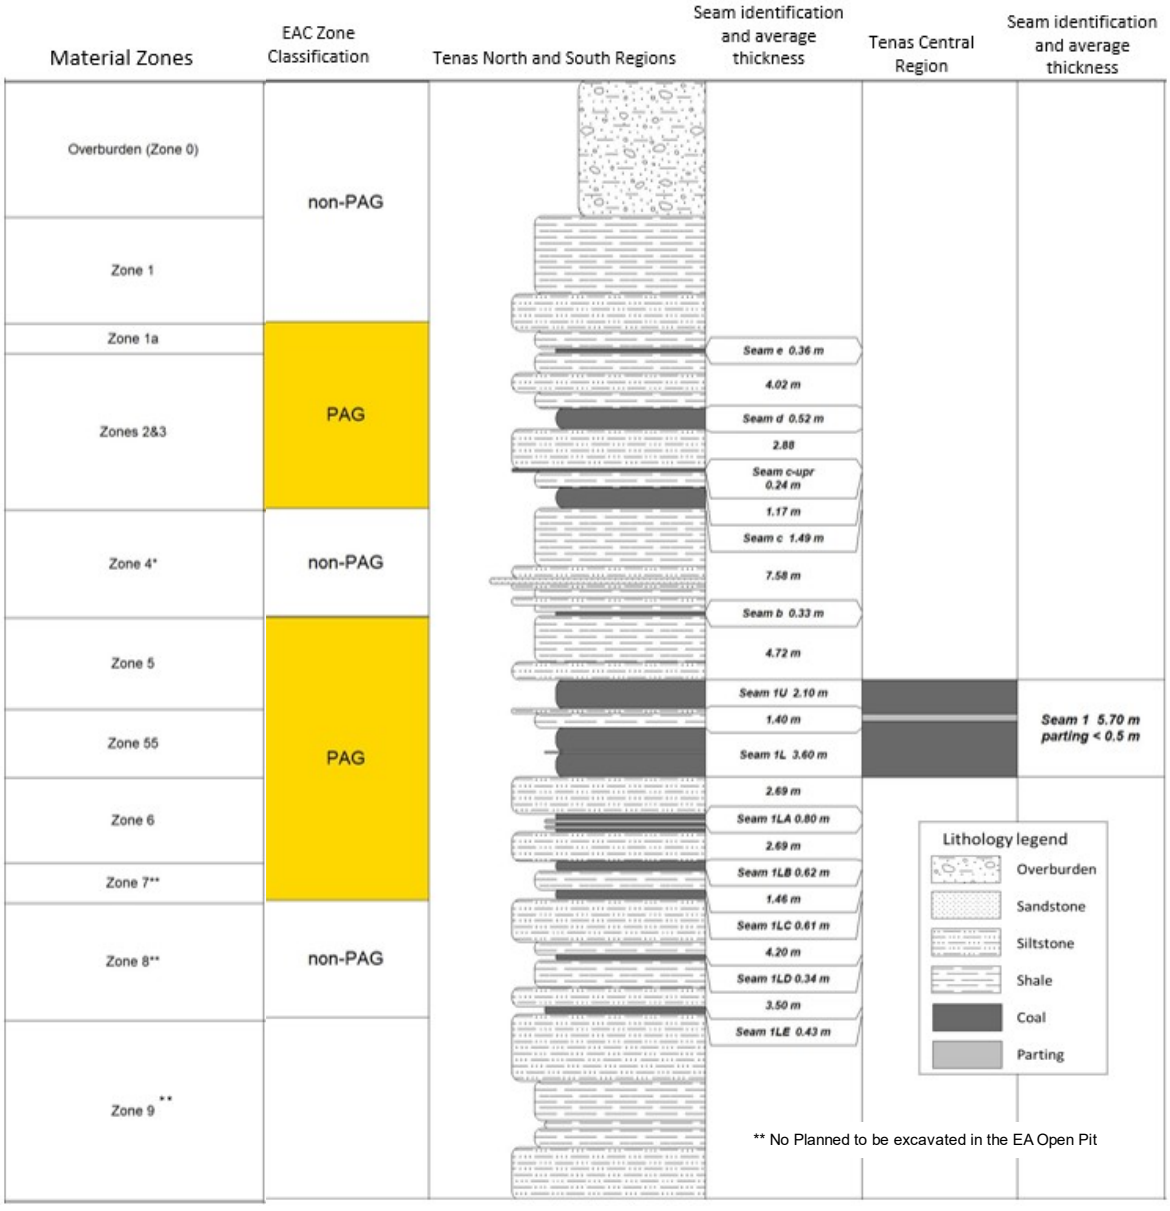

Figure 2-2. Tenas Deposit Stratigraphic Zones

2.2 Geochemical Characterization Study

Two geochemical studies have been completed to characterize the acid generating and metal leaching potential of the Tenas deposit:

- Norecol Dames and Moore (1999). Draft Report. Assessment of ARD Potential and Water Quality Predictions. Telkwa Coal Project.
- SRK (2022b). Telkwa Coal – Tenas Project Supplemental Geochemical Characterization.

The Norecol Dames and Moore (1999) study included the collection and analysis of over 700 samples. An additional 173 samples were collected as part of the supplemental geochemical characterization study (SRK 2022b). The supplemental samples were used to confirm the results of the 1999 study and correlate the test results to more up-to-date testing methods. For example, samples collected as part of the Norecol Dames and Moore (1999) study were analyzed for total sulfur only and neutralization potential was determined using the Sobek-NP (1978) method. Results from both studies were combined to form a robust geochemical characterization that is reported in SRK (2022b). The reader is referred to SRK (2022b) for additional detail on the geochemical characterization program including sample selection, collection, testing and results.

The outcomes of these studies indicated that a large volume of the rock to be mined from the Tenas deposit is potentially acid generating (PAG) and that acid generating potential is stratigraphically constrained in zones generally separated by coal seams. The geochemical properties of the deposit were therefore described based on mineable stratigraphical zones. The geochemical testing results indicate that all zones contain some PAG rock; however, there are units that are predominantly PAG versus non-PAG. Based on the site-specific neutralization potential ratio of 2.0 (NPR) and the average bulk geochemical properties, the following zones were characterized as PAG and non-PAG:

- Non-PAG: Zone 1, 4 and 8;
- PAG: Zones 1a 2/3, 5, 55, 6 and 7.

The geochemical characterization results also indicate that coarse and fine processed rock are PAG and overburden samples tested are non-PAG, including construction materials.

2.3 Summary of Mine Material Management Plan

Mining of the Tenas deposit will produce mine rock and processed rock materials. Previous geochemical testing (Norecol Dames & Moore 1999) indicates that the coarse and fine processed rock and a component of the mine rock will be PAG, and management will be required. Management of mine rock and coarse and fine processed rock are summarized in the following sections.

2.3.1 Management of PAG Rock

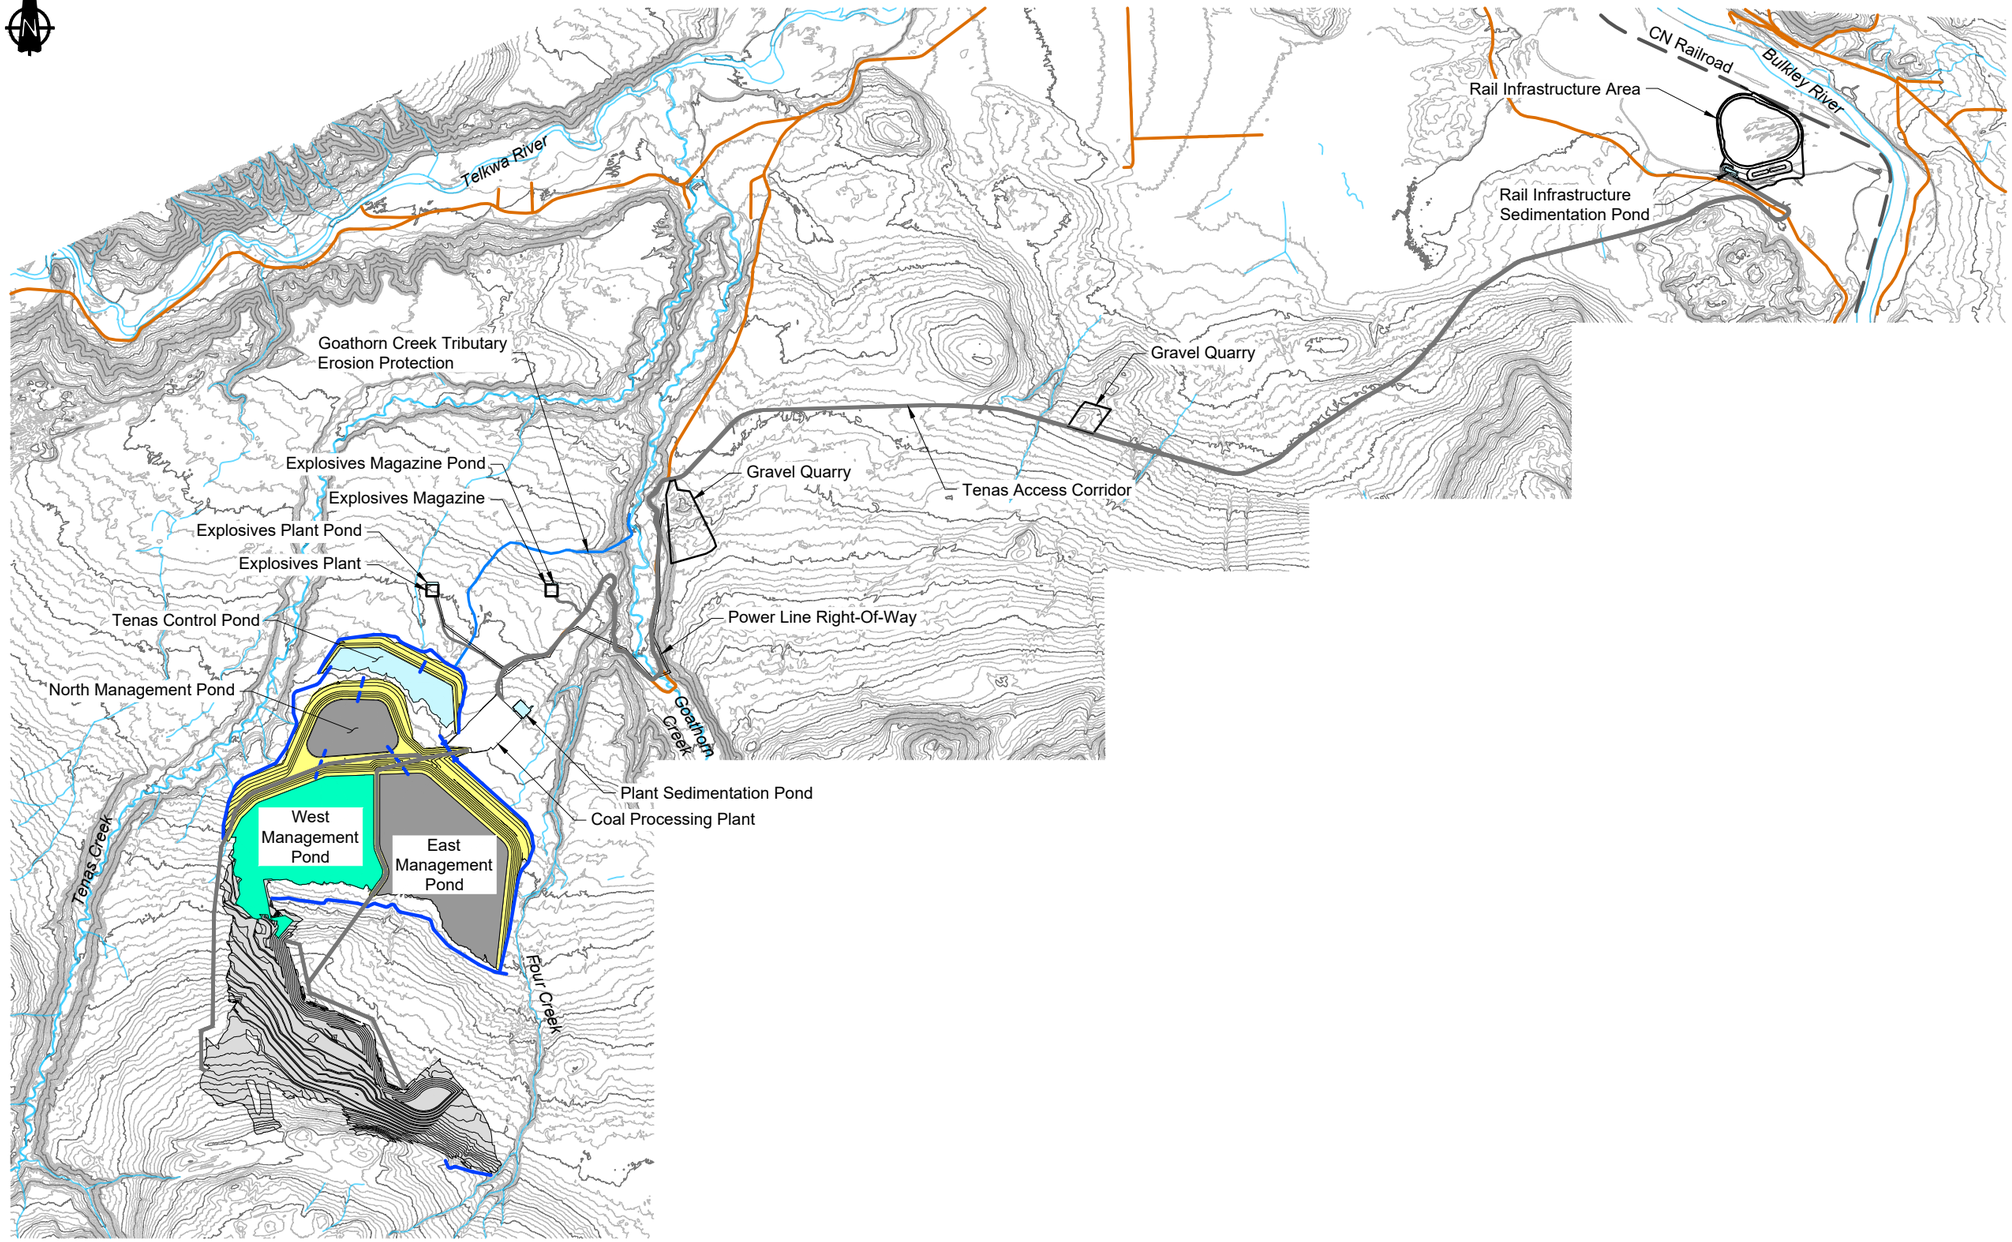
In advance of, and during mining, TML proposes to progressively construct Management Ponds with a combination of excavation and embankments with buttresses (Figure 2-3). The purpose of the management ponds is to store PAG and processed rock in saturated conditions preventing sulfide oxidation, limiting acidic drainage from occurring. Three management ponds will be constructed including the North, West and East Management Ponds. The North Management pond will be constructed first and is located north of the West Management Pond and is external to the open pit. The East Management is constructed next and is south of the NMP and external of the open pit. The last management pond, which is the West Management Pond which is constructed from a combination of excavation for the open pit for the North Phase and construction of an embankment external to the open pit.

PAG rock will first be placed in North Management Pond. PAG rock will be progressively placed in lifts and flooded as each lift is completed so that exposure of rock to atmospheric oxygen is minimized. TCL is proposing to place PAG rock including processed rock underwater before it becomes acid generating.

Once the storage capacity of the pond has been reached, storage will begin in the East Management pond and then the West Management Pond. The three management ponds will be independent of one another allowing different water levels and PAG material levels in each of the ponds as conditions require. The Management Ponds will be maintained with at least a two-metre water cover once PAG material disposition has been completed.

2.3.2 Management of non-PAG Rock and Overburden

Non-PAG rock will be used to progressively backfill the open pit during operations and for constructing portions of the embankments and buttresses for the Management Ponds and Control Ponds. Some non-PAG rock will also be used to cap PAG material in the management ponds once the PAG material has reached its design elevation. Non-PAG rock will be placed in lifts into water, keeping the water level at least 1 metre above PAG rock and at or below the non-PAG placement platform. A 1.5 metre thickness was selected for non-PAG as this is below the expected change in water levels during the Post-closure phase so that this material is never above water.



Overburden will be stored in the buttresses during operation and used as a cover material over non-PAG rock placed in the management ponds.

2.3.3 Management of Processed Rock

Coarse and fine processed rock materials are expected to be PAG and will also be placed in the Management Ponds with the PAG rock (Figure 2-3).

2.3.4 Open Pit Walls

Most of the open pit will be backfilled during the Operation phase. However, a small portion of the hanging wall will exist at post-closure. Meteoric water contacting the open pit walls will report to the end pit lakes, with one of them draining northwards by gravity and mix with Management Pond water prior to discharging into the surrounding environment while the other one discharges to Four Creek once its water quality meets regulatory requirements. Until this time, this end pit lake also drains toward the north.

3 Conceptual Model

3.1 Unsaturated Mine Rock & Processed Rock

Pyrite (FeS_2) is the main sulfide mineral in PAG rock and processed rock at the Project (SRK 2022b). Under natural conditions, pyrite is stable in bedrock where it is isolated from atmospheric oxygen. However, following blasting and excavation of the bedrock, pyrite in the rock mined will be exposed to atmospheric oxygen prior to being placed in the management ponds and will begin to oxidize producing sulfate, ferrous iron, and acidity (Rxn1).

$$FeS_{2\,(s)} + \frac{7}{2}O_{2\,(g)} + H_2O_{\,(l)} \leftrightarrow Fe^{2+}{}_{(aq)} + 2SO_4{}^{2-}{}_{(aq)} + 2H^+{}_{(aq)} \text{ (Rxn 1)}$$

Under oxidizing conditions, ferrous iron liberated during sulfide oxidation will subsequently oxidize to ferric iron in neutral pH producing additional acidity according to the following reaction:

$$Fe^{2+}{}_{(aq)} + \frac{1}{4}O_{2\,(g)} + 2\frac{1}{2}H_2O_{\,(l)} \leftrightarrow Fe(OH)_{3\,(s)} + 2H^+{}_{(aq)} \text{ (Rxn 2)}$$

Although oxidation of mine rock and processed rock for the Project will release acidity, acidic conditions are not predicted to occur immediately since these materials also contain carbonate minerals that will neutralize the acid according to the following reactions:

$$CaCO_{3(s)} + H^+{}_{(aq)} \leftrightarrow HCO_3{}^-{}_{(aq)} + Ca^{2+}{}_{(aq)} \text{ (Rxn 3)}$$

$$CaCO_{3(s)} + 2H^+{}_{(aq)} \leftrightarrow H_2CO_{3(aq)} + Ca^{2+}{}_{(aq)} \text{ (Rxn 4)}$$

Depletion calculations (SRK 2022b) indicate that the lag times to acid generation are on the order of years (>5 years based on the average bulk rock properties). The lag time to acid generation prediction based on HCTs was confirmed by the barrel testing results. Barrel 6, which is a composite sample of rock from Zones 6 and 7, became acid generating in October 2023, four years after the barrel program was initiated. SRK (2022b) indicated that these zones were non-PAG based on their average bulk geochemical properties. However, the weighted barrel 6's NPR (0.5) was more closely aligned with the minimum and P5 NPR observed for these zones (see Table 4 in SRK (2022b)). The lag times to the onset of acid generation based on the Zone 6 and 7 minimum NPRs ranged from 3 to 5 years.

TML proposes to place PAG rock identified by verification testing and processed rock in the management ponds under saturated conditions within an average of six months after blasting but no more than 12 months. Theoretically, this will limit sulfide oxidation (i.e., oxygen becomes a limited reactant in reaction 1 limiting oxidation of the PAG rock and coarse and fine processed rock precluding acidic conditions at the Project. However, any oxidation products that are produced prior to placement of PAG rock and processed rock underwater will be flushed and dissolve in water stored in the management ponds.

At closure TML will cap saturated PAG rock and coarse and fine processed rock in the management ponds with non-PAG rock. The non-PAG rock will be below the active water level in the management ponds and will be saturated. Any oxidation products that have accumulated on non-PAG rock surfaces will also be flushed when the rock is placed in the management pond.

3.2 Unsaturated Non-PAG Rock

Non-PAG rock that is not used in the management pond cover will be used to backfill the open pit and used in portions of the embankments and buttresses with approximately 50% remaining unsaturated in

post-closure. Under these conditions, the rock will continually oxidize according to Reaction 1 (see Section 3.1) producing oxidation products that will be dissolved in meteoric water contacting the rock. However, non-PAG rock contains more neutralization potential than acid generating potential and the sulfide is predicted to be consumed prior to the neutralization potential (SRK 2022b) and acidic drainage from exposed non-PAG rock will not occur. The non-PAG rock will provide a continuous source of element load under neutral conditions.

3.3 Overburden

Overburden that is stripped during mining will be mixed with unsaturated waste rock for use in the buttresses and open pit backfill. Overburden has been characterized as having low sulfur content (SRK 2022b) and is classified as non-PAG. The small amount of sulfide in the overburden will oxidize according to Reaction 1 producing oxidation products that will be solubilized by incident precipitation. Like unsaturated waste rock, the overburden will provide a continuous source of element load that is soluble under neutral conditions.

3.4 Open Pit Wall Rock Runoff

Mining of the Tenas Project will result in open pit walls that are exposed to atmospheric oxygen until they are progressively covered with non-PAG rock and/or overburden during the Operation phase with any remaining uncovered open pit walls being covered in the Decommissioning and Reclamation phase. Sulfides that are present in the open pit wall rock will oxidize according to reaction 1 (Section 3.1) producing sulfate, acidity, ferrous iron, and release of trace chalcophile elements. Soluble oxidation products will be flushed from exposed open pit wall surfaces in meteoric water contacting the wall rock.

The open pit will be progressively backfilled with non-PAG rock and/or overburden during operations reducing the exposure of open pit wall to atmospheric oxygen. Oxidation of open pit wall rock that is covered with backfill will be reduced by limiting oxygen ingress.

At closure, two end pit lakes will form in the backfilled open pit. A footwall will exist above the end pit lakes composed mainly of Zone 6 sedimentary rock. Based on the site-specific NPR criterion (2.0), this unit PAG; however, as discussed in Section 2.3.4, the majority of the exposed pit walls will be covered. The end pit lake will be a mixture of wall rock runoff, direct precipitation and runoff from non-PAG backfill.

The pit lake will drain by gravity and mix with the Management Pond before being discharged during closure.

3.5 Processed Coal Stockpile Runoff

Processed coal will be temporarily stored at the Rail Infrastructure area in two stockpiles prior to being transported from the site to Ridley terminals. While the processed coal is stored, it will oxidize but long-term oxidation is not a concern since processed coal will only be stored for short durations prior to being loaded into rail cars. Soluble load from the processed coal stockpiles will be collected in the Rail Infrastructure Sedimentation Pond to allow suspended solids to settle.

4 Source Term Derivation Methods

Consistent with SRK (2022b), source terms using the barrel testing results were developed in two ways: concentrations and load flushing rates. Unsaturated mine rock, overburden and wall rock runoff source terms were expressed as concentrations. Concentrations were estimated by scaling barrel testing results and mixing estimated annual loads in predicted annual volumes of water and evaluating if the predicted concentrations would be limited by secondary mineral precipitation. PAG rock, coarse and fine processed rock and some non-PAG rock will be stored permanently underwater in the management ponds. Solute produced through oxidative weathering once these materials have been exposed will be flushed from rock surfaces when they are placed in the management ponds. The source term for these materials is therefore represented by a flushing term in milligrams per bank cubic metre (mg/bcm) of rock, also estimated using scaled barrel testing results.

Processed rock (e.g., coal and rejects) barrels were not constructed since there was insufficient material available. Source terms for coal and rejects have therefore not been updated. The reader is referred to SRK (2022a) for the coal and reject source terms. The particulate concentrations source term has also not been updated since it is independent of kinetic testing release rates (i.e., it was derived based solid-phase static testing results) and is not included in this report. The reader is referred to SRK (2022a) for details on the derivation methods and results of these source terms.

The following subsections provide the inputs and assumptions for each of the source terms based on the barrel testing results.

4.1 Mine Rock Solute Release Rates

A key input into the source term calculations is the mine rock solute release rates. Barrels were constructed from rock representative of each rock zone and the barrel release rates were used to represent the release rates from individual rock zones. Composite samples for each barrel were prepared from excess sample stored at Bureau Veritas Laboratories in Burnaby, British Columbia. Sample, varying in mass from one to 110 kg were selected for use in the barrels until a minimum mass of 200 kg was achieved. Zones with insufficient sample mass to achieve 200 kg (e.g., Zone 4 PAG and Zone 4 non-PAG) were supplemented with sample from other zones with similar geochemical properties (SRK 2024b).

Leachate sampling from the barrels has been conducted intermittently since October 2019 until present. The source terms only consider samples collected until November 2023. Seven to nine samples have been collected from each barrel during this period. The monitoring results from these sampling events was used to estimate barrel release rates according to the following formula:

$$L_j = C_j * \frac{V}{m} / t \qquad \text{(EQ 1)}$$

Where:

L_j is the load of parameter j expressed in mg/kg/week

C_j is the concentration of parameter j in the leachate sample in mg/L

V is the volume of the sample in L

m is the total mass in the barrel in kg

t is the time between sample events in weeks

The average release rate calculated from each sampling event was used in the source term calculations. As noted in Section 3.1, Barrel 6 began to produce acidic leachate in October 2023. Release rates from this sampling event were not included in the average barrel release rate calculations since the conceptual model for the Project is rock will be managed to minimize acid generation and release rates under acidic conditions are not expected to occur.

As noted above, the barrels were constructed of crushed drill core. This results in the barrel samples having a higher reactive surface area in comparison to rock that will be blasted and used in the pit backfill or construction of the buttresses. Scaling factors were applied to the barrel release rates to account for this difference. Details of the scaling factors that were used are discussed in the following subsections.

4.2 Unsaturated Mine Rock and Overburden

4.2.1 Base Case Source Term

Unsaturated non-PAG rock and overburden will be used as backfill in the open pit as well as in construction of the management pond buttresses. The backfill will become partially saturated as the open pit floods at closure. Unsaturated portions of the backfill will continue to oxidize and produce soluble load that will be mobilized in meteoric water interacting with the mine rock.

Annual unsaturated mine rock concentrations were estimated as follows:

$$C_{j=\frac{L_{j,annual}}{Q_{annual}}} \quad \text{(Eq 2)}$$

Where: C_j is the concentration of constituent j

$L_{j,annual}$ is the annual load of constituent j released from exposed mine rock and/or overburden

Q_{annual} is the annual average flow contacting exposed mine rock and overburden

Source term concentrations using Equation 2 were estimated for the following timeframes:

- Pit Backfill
  - End of East Management Pond (EMP)
  - End of Mining (EOM)
- Buttresses
  - End of North Management Pond (NMP)
  - End of EMP
  - End of West Management Pond (WMP)

These periods were selected to evaluate changes to water quality throughout the life of mine (LOM) at key stages of the mine development. In the source term calculations, mine rock and overburden present in the above timeframes was assumed to be unsaturated and produce soluble load. In reality, a portion of the waste rock will become inundated as the pit is progressively backfilled. This assumption results in a conservative estimate of the pit backfill and buttress drainage water quality.

The mine plan indicates that the buttresses will be constructed using overburden and mine rock sourced from Zones 1 and 4. Table 4-1 provides a summary of the cumulative mine rock and overburden volumes and tonnages associated with each of the model timeframes. Mine rock tonnages were estimated using an assumed density of 2.55 grams per bank cubic centimetre (g/bcc) and a density of 2.0 g/bcc was assumed to estimate overburden tonnages (TML 2024, pers. comm.). The respective barrel release rates were prorated in proportions estimated based on the volumes provided in Table 4-1 to estimate the unit solute release rates for the backfill and buttresses at each of the model timeframes. This rate was multiplied by the total mass at each timeframe to estimate the annual load produced.

As noted in Section 4.1, scaling factors were applied to the barrel release rates to account for testing and operational field differences. A generic scaling factor of 0.2, based on SRK's experience at other coal mines in British Columbia, was applied to account for grain size differences between the barrel tests and mine rock that will be produced during operations. Channelization and temperature scaling factors, which were applied to the HCT release rates (SRK 2022b), were not applied to the barrel release rates. Due to the size of the tests, the barrels will have a higher degree of flushing in comparison to rock stored in the backfill and in the buttresses and additional channelization is expected to occur under operational conditions. It is difficult to quantify the degree of flushing in the barrels and a channelization factor was conservatively not included in the barrel release rate estimates.

The barrels only contain 200 kg of material and will therefore be more susceptible to temperature variations in comparison to the rock and overburden used in the backfill and buttresses which will exhibit internal heating from sulfide oxidation. However, the average temperature of the water samples collected from the barrel tests was approximately 10°C. It is assumed a similar internal temperature will occur in the mine rock backfill and buttresses from oxidation of sulfide minerals and carbonaceous rock and release rates were therefore not corrected for temperature differences.

Table 4-1. Summary of Unsaturated Mine Rock & Overburden Quantities

Facility	Cumulative Volume (bcm)			Cumulative Tonnage (Mt)		
	Mine Rock		Overburden	Mine Rock		Overburden
	Zone 1	Zone 2		Zone 1	Zone 2	
Backfill

Source: https://srk.sharepoint.com/sites/NACAPR002933/Internal/Task 500 Source Term Updates/01_Source_term_updates/[Telkwa_backfill_buttress_volume_summary_CAPR002933_mkh_r0.xlsx

The annual scaled release rate was divided by the annual average volume of water contacting unsaturated mine rock (SRK 2024a) using Equation 2 to estimate the annual average constituent concentrations in drainage from unsaturated mine rock and overburden. Predicted water qualities were entered into the publicly available speciation and mass transfer code PHREEQC v.3 (Parkhurst and Appelo 1999), developed by the United States Geological Survey (USGS), to evaluate mineral and gas phases that were supersaturated in solution. The mineral and gas phases included in the model are presented in Table 4-2. Supersaturated mineral phases were allowed to precipitate from solution and

sorption to ferrihydrite was also considered using the default values of Dzombak and Morel (1990). Sorption to ferrihydrite will limit parameters that form oxyanions (e.g., arsenic) and other ligands from remaining in solution.

Table 4-2. Model Equilibrium Phases

Mineral	Empirical Formula	Mineral	Empirical Formula	Mineral	Empirical Formula
Carbon Dioxide	CO_2 (g)	Chalcanthite	$CuSO_4 \cdot 5H_2O$	Calcium Molybdenum Oxide	$CaMoO_4$
Gibbsite	$Al(OH)_3$	Ferrihydrite	$Fe(OH)_3$	Nickel Hydroxide	$Ni(OH)_2$
Otavite	$CdCO_3$	Melanterite	$FeSO_4 \cdot 7H_2O$	Zinc Hydroxide	$Zn(OH)_2$
Brochantite	$Cu_4SO_4(OH)_6$	Anglesite	$PbSO_4$	Smithsonite	$ZnCO_3$
Copper Hydroxide	$Cu(OH)_2$	Birnessite	$MnO_2 \cdot nH_2O$	Goslarite	$ZnSO_4 \cdot 7H_2O$
Malachite	$Cu_2(CO_3)(OH)_2$	Manganite	MnO(OH)	Gypsum	$CaSO_4 \cdot 2H_2O$
Azurite	$Cu_3(CO_3)_2(OH)_2$	Lead Molybdenum Oxide	$PbMoO_4$		

4.2.2 High Case Source Term

To account for variability in the source term inputs, a high case source term was developed. The high case source term was estimated by increasing sulfate concentrations to concentrations that are in equilibrium with gypsum (i.e., sulfate concentrations are assumed to be saturated in solution) under the assumed pH and redox conditions. Equilibrium with gypsum was achieved by incrementally adding anhydrite ($CaSO_4$) to the predicted base case solution (Section 4.2.1) until sulfate concentrations reached steady state. Concentrations of other elements were scaled up in the high source term by preserving the metal sulphate ratios (M/SO_4) in the base case source term. A key assumption in this approach is that elements in the solution are chalcophile which could result in an overprediction of non-chalcophile elements. Mineral saturation was evaluated by equilibrating the high case unsaturated mine rock water quality with the same mineral phases (Table 4-2) as the base case solution.

4.3 Saturated Mine Rock

4.3.1 PAG Rock Flushing Source Term

PAG rock produced during mining of the Tenas deposit will be permanently stored in saturated conditions in the management ponds. Placement of PAG rock in the management ponds will result in flushing of oxidation products accumulating on the surfaces of the PAG following exposure during mining. A unit annual flushing rate, in kilograms per tonne of rock (kg/tonne), was estimated by proportioning scaled barrel solute release rates (Section 4.1) in the relative proportion of each zone to be mined in each year (Table 4-3). The same grain size factor used to estimate loadings from unsaturated waste rock (Section 4.2.1) was applied to estimate the mass flushed from PAG rock.

A key input to the PAG rock flushing source term is the exposure time prior to placement in the management ponds. TCL proposes to have PAG rock including processed rock placed in the management ponds within an average of six months which was used when developing the PAG rock flushing source term. Like the unsaturated mine rock source term, a high case was also developed where PAG mine rock was assumed to be exposed for 12 months.

Table 4-3. Annual PAG Rock Volumes and Relative Proportions

Year	Mine Rock Volume (bcm)								Mine Rock Proportion						
	Zone 1a	Zone 2	Zone 3	Zone 4 (PAG)	Zone 5	Zone 55	Zone 6	Total	Zone 1A	Zone 2	Zone 3	Zone 4 (PAG)	Zone 5	Zone 55	Zone 6

4.3.2 Non-PAG Rock Flushing Source Term

As PAG material reaches its designed elevation, non-PAG rock will then be placed in lifts above the saturated PAG. Once this lift is completed, overburden is then placed in a maximum of a 3 metre lift to form dry land reclamation. Surface soils will then be placed in a lift thickness of approximately 30 centimetres. The non-PAG rock will be placed in aqueous conditions and the majority of the overburden will be unsaturated. Oxidation products that have accumulated on the non-PAG mine rock following exposure during mining will be flushed from the surfaces as the rock is placed in the management pond.

TML proposes to use non-PAG rock source from Zone 1 in the management pond cover. A unit flushing rate, in kg/tonne, was estimated by scaling the Zone 1 average barrel release rates results to account for differences between testing and operational field conditions. The same scaling factor used to estimate the PAG rock flushing term was applied (i.e., grain size factor). Flushing rates were estimated for six- and 12-month exposure periods.

4.3.3 Flooded non-PAG Rock Backfill

Approximately 50% of the non-PAG rock in the backfill will become flooded in Post-closure. Mass that accumulates in the backfill will be flushed during flooding. As discussed in Section 4.2.1, unsaturated mine rock is not assumed to have a channelization factor and is assumed to have a high leaching efficiency since there is uncertainty in quantifying the degree of channelization in the barrel tests. This provides a conservative estimate of the drainage quality from unsaturated materials, but no mass accumulation will occur using this approach. Therefore, flushing of submerged mass is not accounted for in the source terms.

The water balance model (SRK 2021) indicates there is no hydraulic connection of water stored in the flooded backfill to the management ponds. However, a small volume of the flooded backfill water will report to the groundwater system. Water balancing modelling indicates that the water losses from the flooded backfill represent less than one percent (i.e., 0.4%) of the total flow to the groundwater system. As noted above, there is a high degree of uncertainty in estimating the residual load that will be flushed from the flooded backfill and since the flow is effectively negligible to other flows, a source term was not developed for the flooded non-PAG rock backfill.

4.4 Wall Rock Runoff

Exposed wall rock surfaces will produce oxidative load that will be flushed by meteoric water. An annual pit wall drainage water quality was estimated using equation 2; however, in this instance $L_{j,annual}$ is the annual load of constituent j released from exposed wall rock surfaces and Q_{annual} is the annual average flow contacting the exposed wall rock. TML proposes to progressively backfill the open pit during operations. This will continually change the areas of rock exposed in the pit walls. To evaluate changes to the wall rock runoff composition, source terms were developed for the following time periods, which correspond to backfilling of different areas and volumes placed in the open pit:

- End of placement of PAG rock in the North Management Pond (NMP)
- End of placement of PAG rock in the East Management Pond (EMP)
- End of the Operation Phase (EOM)

The reactive mass of each stratigraphic zone in the open pit walls was estimated by multiplying the exposed surface area of each of the zones in the open pit walls by an assumed depth of fractured rock for each of the above time periods. Surface areas for each time period are provided in Table 4-4. The fractured rock depth was assumed to be two metres for blasted areas and five centimetres for free dig areas and the floor of the pit. A density of 2.55 g/cc was assumed to estimate the reactive mass exposed in the pit walls.

The average release rates from each barrel were prorated in relative proportions calculated based on the exposed surface areas (Table 4-4) to estimate the unit solute release rates for the backfill. As discussed in Section 4.1, barrels tests are not available for processed rock. The approach described in SRK (2022a) was used to represent loadings from exposed coal seams. This rate was multiplied by the total reactive mass in the open pit walls to estimate the annual load produced. The annual load was scaled to field conditions using the grain size differences. Since HCT release rates were used to represent release rates from exposed coal seams, a temperature factor was applied to coal (SRK 2022a). It was assumed that the entire fractured rock zone in the open pit walls would be flushed, and a channelization factor was not included.

The annual scaled release rate was divided by the annual average volume of water contacting wall rock runoff (SRK 2022) to estimate drainage concentrations using equation 2. The annual volume for each time period is presented in Table 4-5. Mineral solubility was evaluated and phases that were identified to be supersaturated in solution were allowed to precipitate or off-gas (for gas phases). Mineral phases that were considered are provided in Table 4-2. Sorption to ferrihydrite was also included when this mineral phase precipitated.

Like the unsaturated mine rock source term, a high case wall rock source term was estimated by forcing the predicted solutions to gypsum saturation through incremental anhydrite addition in PHREEQC. Element sulfate ratios in the base case source term were assumed when calculating concentrations of other constituents. The scaled-up solution was subsequently equilibrated with the mineral phases presented in Table 4-2 and sorption to ferrihydrite was permitted when this mineral phase precipitated.

During operations it is assumed that the pit backfill will be fully oxygenated. Therefore, the wall rock that is below the backfill will also be reactive. A load from the backfilled pit walls was also estimated using the same assumptions as exposed wall rock. The annual load originating from covered walls at the end of EMP and EOM was added to unsaturated mine rock load (Section 4.2). The load was estimated by prorating the scaled barrel loads (and HCT for exposed coal seams) in proportions calculated based on the backfilled pit wall surface areas (Table 4-6).

5 Source Terms

The following sections present the Tenas Project source terms. The source terms do not represent discharge water quality and how the mine rock flushing source terms influence site drainage water quality cannot be quantified until they are carried forward into the site wide water and load balance. Therefore, limited interpretation of the source terms is included in the following sections. Detailed interpretations of the site wide water and load balance model results using these source terms are included in SRK (2024a).

5.1 Unsaturated Mine Rock & Overburden

5.1.1 Pit Backfill Source Term Water Quality

The base case and high case pit backfill source terms for end of EMP and EOM are provided in Table 5-1. The charge imbalance for the base case and high case solutions were less than 10%. This is considered acceptable for a modelled solution that have average inputs from multiple sampling rounds and charge imbalances were not corrected. The pH of solutions is alkaline (8.2 to 8.5) and all modelled constituent concentrations are higher in the high case in comparison to the base case source terms since gypsum was not predicted to be supersaturated in the base case source term and the scaling method (i.e., preserving element/sulfate ratios; see Section 4.2.2) results in constituent concentrations being higher in the high case solutions. Predicted constituent concentrations are higher at the EOM in comparison to the end of EMP source terms because of increased reactive mass in the pit backfill (Table 4-1).

5.1.2 Dam/Buttress Source Term Water Quality

The base case and high case dam/buttress source term water quality for end of NMP, end of EMP and end of WMP are provided in Table 5-2. The charge imbalance for the base case and high case solutions were less than 10%. This is considered acceptable for a modelled solution mixing average inputs from multiple HCTs and charge imbalances were not corrected. The pH of solutions is alkaline ranging from 7.6 to 8.3.

The trends in predicted concentrations are like the pit backfill water quality. For example, the modelled constituent concentrations are higher in the high case in comparison to the base case source terms since gypsum was not predicted to be supersaturated in the base case scenario. Constituent concentrations are predicted to increase throughout the LOM because of the reactive mass increasing (Table 4-1).

Table 5-2. Dam/Buttress Source Term Water Quality

5.2 Saturated Mine Rock

Saturated rock flushing terms are presented in kg/tonne. The influence of flushing of rock as it is placed in the management ponds cannot be quantified until it is carried forward into the water and load balance. Annual PAG rock flushing rates for the six- and 12-month exposure periods are provided in Table 5-3 and Table 5-4, respectively. The non-PAG rock flushing source terms are provided in Table 5-5, respectively.

Table 5-3. PAG Rock Annual Flushing Source Term – Six Month Average Exposure

5.3 Open Pit Wall Rock Runoff

The base case and high case open pit wall rock runoff source terms for the End of NMP, End of EMP and EOM are provided in Table 5-6. The charge balance in of the wall rock source terms is less than 10%, which is considered reasonable for solutions based on averaging several release rates in the field barrel tests. The pH of solutions was alkaline (7.4 to 8.1) and maximum pit wall runoff concentrations occurred at the end of the EMP since this timeframe represents the maximum exposure of pit wall and has the highest reactive mass (Table 4-6).

Most of the constituents were higher in the high case source term in comparison to the base case. Concentrations of iron were lower in the high case source terms. Iron concentrations are low in both scenarios since it is solubility constrained through ferrihydrite ($Fe(OH)_3$) precipitation. Lower iron concentrations occur in the high case source term since these solutions are more alkaline reducing the ferrihydrite solubility (i.e., more ferrihydrite is predicted to precipitate in the high case scenario).

Table 5-6. Open Pit Wall Rock Runoff Source Terms

6 Summary

SRK (2022a) developed geochemical source terms by scaling HCT testing results to field conditions. A comparison to the scaled HCT and barrel testing results indicated that the release rates of some constituents are higher in the barrels in comparison to the HCT. The geochemical source terms were updated using the barrel release rates. The barrel release rates are considered more appropriate for estimating site drainage water quality because they are more representative of solute release rates under field conditions.

Barrels were constructed using mine rock sample rejects and overburden. Insufficient processed rock (e.g., coal, coarse rejects, etc.) sample precluded barrels being constructed for these materials. Base The following source terms were updated using the barrel testing results:

- Unsaturated non-PAG & overburden
  - Pits backfill
  - Dams/buttresses
- Saturated non-PAG rock
- Saturated PAG rock
- Open pit wall rock runoff

The following source terms were not updated and the SRK (2022a) source terms remain current:

- Processed rock
- Processed coal stockpile runoff
- Particulate concentrations

The above source terms will be carried forward into the site wide water and load balance to evaluate the mixed project discharge water quality. To evaluate uncertainty in the model, both the base case and high case scenarios should be evaluated.

EXECUTIVE SUMMARY

Okane Consultants (Okane) are providing support to evaluate the development of suboxic conditions for the backfill of non-potentially acid generation (NAG) mine rock into the Open Pit for Telkwa Mining Limited (Telkwa) at their proposed Tenas Project in northwest British Columbia. The current scope focuses on placement of NAG mine rock. The objective of the scope was to develop geochemical source terms for the backfilled mine rock that reflect the construction and reclamation schedule, and the resulting hydrological and oxygen conditions of the backfill.

The source terms were developed using a two-dimensional oxygen model to evaluate the size, location, and timing of suboxic (low oxygen concentration) conditions within the NAG backfill. The formation of suboxic conditions limits oxidation rates of sulfide minerals and decreases the loads of constituents of interest released from sulfide oxidation to the receiving environment. The source terms will be used as inputs for the site-wide water quality model that integrates seepage and chemical loads from all mine domains to understand the overarching water quality effects of the Project on the receiving environment. All years presented herein refer to mine plan years.

Three scenarios were chosen to evaluate the development of suboxic conditions. The three scenarios were:

- Scenario #1: Poorly graded till and sandstone mine rock;
- Scenario #2: Well graded till and mine rock mix (60% siltstone, 35% mudstone, and 5% sandstone);
- Scenario #3: Well graded till and mine rock mix (60% siltstone, 35% mudstone, and 5% sandstone) with no internal cover layers.

During the covered time period for all modelled scenarios, two sequential cover surface conditions (grass cover followed by the establishment of mature forest) were used to simulate the maturing of vegetation on the cover system. These surface conditions affected how oxygen and water move into the cover material and underlying NAG backfill. For a five-year period directly after cover placement the simulation used a grass surface; following this five-year period, a forest surface was used for the remainder of the model timeframe.

GoldSim seepage modelling for the NAG backfill demonstrated a significant reduction in stabilized seepage rates between the modelled scenarios. Stabilized seepage rates for Scenarios #2 and #3 were approximately half of the stabilized rates for Scenario #1. The modelling also demonstrated that the NAG backfill will be wetted up after approximately 40 years in Scenario #1 and approximately 80 years in Scenarios #2 and #3 due to differences in material texture in the cover system. Modelling demonstrated that suboxic conditions within Scenario #1 took approximately 15 years to develop and approximately 13 years in Scenarios #2 and #3 once the cover system was placed. Depths to suboxic conditions varied between the scenarios due to differences in oxygen ingress and net percolation. Scenario #1 had a

long-term depth to suboxia of approximately 15 m while Scenarios #2 and #3 had a long-term depth to suboxia of approximately 3 m.

Estimated stored water volumes increase as mine rock is placed during construction and stabilize after approximately 15 years when construction has ended. Similar to seepage results, the stored water volumes stabilize after approximately 40 years for Scenario #1 and 70-80 years for Scenarios #2 and #3. Stored water volumes in the NAG backfill are predicted to be lower in Scenarios #2 and #3 relative to Scenario #1.

Source terms were developed for Scenarios #1, #2, and #3 using a reactive transport modelling approach. Reactive transport modelling was used to simulate the weathering of sulfide and carbonate minerals and resulting concentrations of related dissolved constituents using mechanistic kinetic weathering rates controlled by the geochemical setting of the NAG backfill. For constituents not directly controlled by sulfide oxidation and carbonate dissolution, a constant loading rate scale-up model was used to develop source terms. The geochemical models were calibrated to on-site kinetic barrel tests containing NAG mine rock and subsequently applied to the full-scale NAG backfill geometry.

The geochemical model incorporated changing cover system surface conditions by changing net percolation into the model for each time period (bare mine rock, grass coverage, and forest coverage). The effects of suboxic zones were simulated by limiting pyrite oxidation to depths where oxygen models simulated oxic conditions.

In general, concentrations for modelled parameters were similar between all scenarios. Although it was evident that less pyrite oxidation was occurring in the Scenario #2 and #3 models due to the larger suboxic zones, which resulted in lower mass release of oxidation products, decreased infiltrating water volumes (i.e., less dilution) in these scenarios resulted in similar concentrations as seen in Scenario #1. The primary benefit of the well-graded cover system scenarios is the overall decrease of released load of oxidation products (e.g., selenium and sulfate) from the NAG backfill. Scenarios #2 and #3 consistently had lower chemical loading relative to Scenario #1 resulting in approximately half the mass of oxidation products released from the NAG backfill on an annual basis. Scenarios #2 and #3 had similar chemical loading due to similar lag-times to suboxic zone development and depth to suboxic conditions. Additionally, geochemical source terms of the NAG backfill from the current model were comparable, although generally slightly lower, than source terms initially developed for the backfill (SRK, 2022a). The NAG backfill source terms from this modelling work will be integrated into the site wide load balance model to quantify the effects of the backfill on water quality around the Tenas project.

1 INTRODUCTION

1.1 Project Description

Telkwa Mining Limited (Telkwa) are proposing to develop the Tenas Project (Project), located approximately 25 km southwest of the town of Smithers in northwest British Columbia (BC) within the Telkwa and Bulkley River watersheds. The Project consists of an open pit, backfill, external stockpiles, water management ponds, control ponds, coal processing plant, and rail infrastructure. Elevation of the Project ranges from 750 to 1,050 meters above sea level (masl), with a median elevation of 800 masl. The Project is within the Ministry of Environment and Climate Change Strategy (MECCS) Zone 8 – Nechako Plateau, close to the border with Zone 9 – Southern Hazelton Mountains (Ahmed and Jackson, 2013). The MECCS hydrological zones are areas of homogeneous hydrologic and geomorphic characteristics.

1.2 Project Objectives and Scope

Okane Consultants (Okane) is providing support to develop source terms for three scenarios of backfill NAG mine rock in lifts using bottom-up construction methodology with overburden covers within the Open Pit provided by Telkwa. The objective of the backfilled design is to limit oxygen and water ingress to minimize the release of potential contaminants of concern such as selenium and sulfate to the receiving environment.

A geochemical model that incorporated both a mechanistic reactive transport model and geochemical scale-up model was developed to simulate long-term water quality of mine rock backfilled into the Open Pit. Seepage water quality results from the geochemical model were developed as source terms to be used in the Tenas site-wide water quality model developed by SRK Consulting (SRK).

1.3 Report Organization

For convenient reference, this report has been subdivided into the following sections:

- Section 2 – Provides pertinent background information for this study;
- Section 3 – Description of modelling processes;
- Section 4 – Modelling results and discussion; and
- Section 5 – Conclusions of the modelling work.

2 BACKGROUND

Source control of contaminants of interest (COIs) is a cutting-edge practice. It demonstrates a significant commitment to minimizing water quality impacts in the region to both regulators and stakeholders. Okane has extensive experience in implementing closure strategies to mine storage facilities, ultimately limiting oxygen ingress and net percolation into the underlying waste material. This working experience has led to development of fully integrated models that link hydrology, oxygen conditions, material properties, mine rock structure and climate to develop source terms for site-wide water quality models.

Okane's experience has shown that there are solutions available to improve source control and water quality, therefore, providing the opportunity to relinquish the site at the end of the mine life versus treating water from the mine rock into perpetuity. Such solutions can include progressive reclamation and the application of oxygen-limiting cover systems which can lead to the development of suboxia within the NAG mine rock storage facilities (MRSFs) to help improve long-term seepage quality by inhibiting the oxidation of sulfide minerals within the SOZ, decreasing the release and production of metal leaching in the lower zones of the MRSF.

Currently for the Project, suboxia is defined as pore gas oxygen concentrations less than 1 vol.%, which results in a dissolved oxygen concentration in pore water of less than 1 mg/L. The NAG mine rock is a large porous mass, which during placement will have oxygen concentration in pore spaces reflecting ambient conditions, or near to ambient conditions. Oxygen within NAG mine rock pore spaces will be depleted because of sulfide (pyrite) oxidation.

2.1 Net Percolation and Oxygen Ingress Classifications

The term 'net percolation' (NP) is used throughout this memo and is defined as presented in Figure 2.1. Precipitation (PPT) that reaches the cover system surface will either be intercepted by vegetation, run off (RO), or infiltrate into the cover system. A portion of the water that infiltrates will be stored in an active zone (ΔS) where water is actively cycled within the soil profile and into the atmosphere. Water stored in the active zone can be evaporated (AE) into the overlying atmosphere or can be removed by plant transpiration (AT); the combination of evaporation and transpiration is referred to as actual evapotranspiration (AET). Water in the cover system can also potentially move laterally as interflow. Water that moves below the active zone and is no longer available to be removed from the system via AET or laterally is defined as NP. NP is infiltrating water expressed as a percentage of average annual precipitation (PPT) that will migrate beyond the active zone because of gravity overcoming the influence of evapotranspiration, resulting in flow of water into the underlying NAG mine rock and overburden cover.

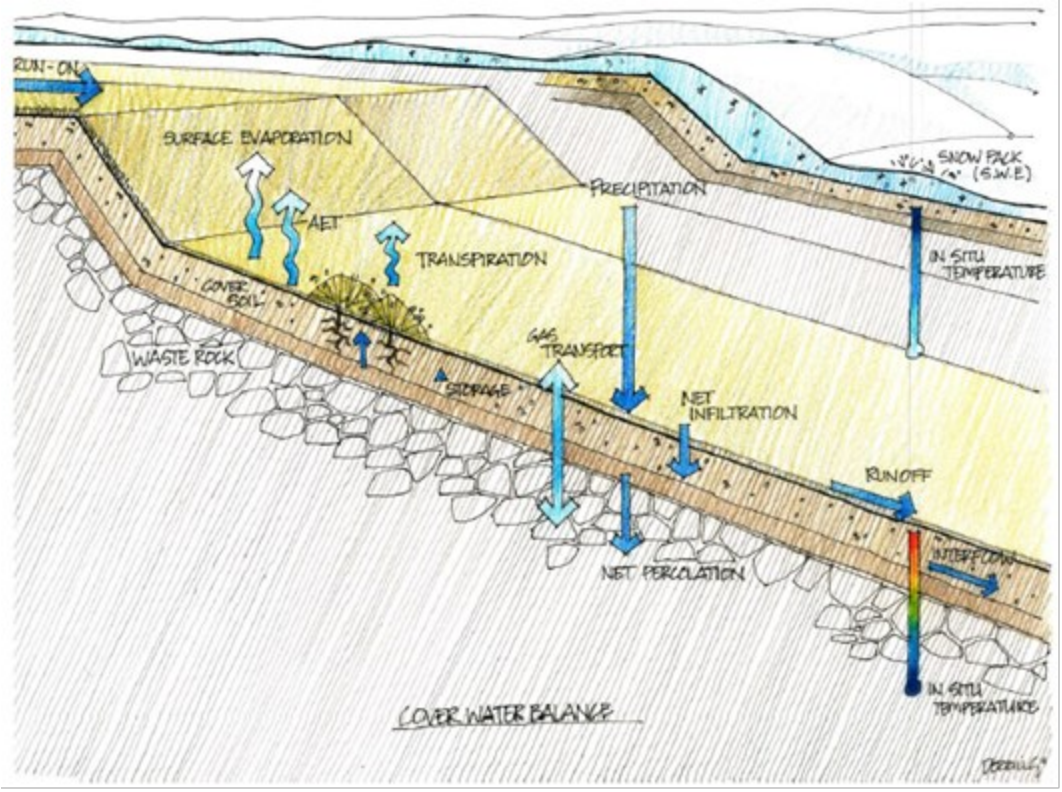

Figure 2.1: Schematic of hydraulic processes that influence performance of a cover system (from INAP, 2017)

As shown by the Project climate data described later in this report, the Project is classified as subarctic (Dfc) using the Köppen-Geiger climate classification (Peel *et al.,* 2007). Based on this classification, the range of cover system performance for the Tenas Project is presented conceptually, as defined in the Global Cover System Design Technical Guidance Document (INAP, 2017), as follows:

- "Very High" NP is greater than 50% PPT;
- "High" NP is between 25% PPT and 50% PPT;
- "Moderate" NP is between 15% PPT and 25% PPT;
- "Low" NP is between 5% PPT and 15% PPT; and
- "Very Low" NP is less than 5% PPT.

Within a single climatic regime, the same range of NP rates may be a result of the influence of differing abilities of a cover system to evapotranspirate water, and to promote runoff and interflow (i.e., lateral flow within the cover system) from the landform. Net percolation rates will also vary from year to year. For example, a high rainfall year (or, more specifically, several successive wetter than average climate

years) may result in a moderate net percolation rate for the year, even for a cover system scenario classified, on average, as having a low net percolation rate.

Cover performance with respect to oxygen (O_2) ingress can also be classified using the Global Cover System Design Technical Guidance Document (INAP, 2017) as follows:

- "Very High" O_2 ingress is greater than 100 mol/m^2/year;
- "High" O_2 ingress is between 50 and 100 mol/m^2/year;
- "Moderate" O_2 ingress is between 10 and 50 mol/m^2/year;
- "Low" O_2 ingress is between 1 and 10 mol/m^2/year; and
- "Very Low" O_2 ingress is less than 1 mol/m^2/year.

Limiting oxygen ingress is often achieved by limiting diffusion or restricting air flow by reducing pressure and/or thermal gradients. Usually, the most effective way to limit oxygen ingress is to create and sustain saturated conditions in a layer within the cover system. O_2 ingress is less challenging to limit in wetter environments where a tension-saturated layer is more easily maintained, and finer-textured material together with the tension saturated conditions will lead to reduced air permeability and therefore, advective gas transport. A similar range of performance exists for O_2 ingress as for NP where rates will vary from year to year. For example, a low rainfall year or several successive drier than average years will reduce the degree of saturation maintained within the cover system and may increase the predicted oxygen ingress rate for the year.

Limiting NP and O_2 ingress are not necessarily mutually beneficial and achieving reductions in either or both is site specific. Depending on available materials for cover system construction, limiting NP may result in less water available to maintain a saturated layer, whereas limiting O_2 ingress may require promoting additional NP. Hence, a technical assessment is required to make decisions on how best to optimize these two aspects to best take advantage of how each facet enhances performance for a particular project.

2.2 Site Specific Attributes

Assessment of the NAG backfill and cover system performance requires analysis of site attributes that constrain design alternatives to achieve the desired performance (INAP, 2017). The following site-specific attributes will be used to define performance of the NAG backfill design at Tenas:

- Climate;
- Hydrogeological setting;

- Materials;
- Vegetation; and,
- Geochemistry.

These key site attributes are described in the following sections based on background data provided by Telkwa.

2.3 Climate

The regional climate is a subarctic climate where winters are cold, averaging around -5°C during the period of November through February with temperatures potentially dropping to -30°C or colder, and summers are warm, with average temperatures greater than 20°C and highs of greater than 30°C are possible. Precipitation occurs as rain during the warmer months, accounting for 60-65% of annual precipitation. Snow accounts for 35-40% of annual precipitation with maximum accumulation of snow occurring in February-March.

The Project falls near the intersection of Dfc (subarctic climate) and Dsc (Mediterranean-influenced subarctic climate) of the Köppen-Geiger climate classification system (Peel *et al.*, 2007) where:

- D – 'continental' where average temperature of the coolest month is < -3 °C, and average temperature of the warmest month is > 10 °C;
- f – 'without dry season' where precipitation is evenly distributed throughout the year;
- s – 'dry summer' where precipitation of the driest month in summer is less than 40 mm and is also less than a third of the precipitation of the wettest month in winter; and
- c – 'cold summer' where one to three months average temperature reach >10 °C but < 22 °C.

2.4 Hydrogeological Setting

The results of historical hydrogeological investigations and *in-situ* testing are presented in Table 2.1. Surficial material is primarily sandy till to silty clay (Piteau, 1997), which is underlain by fractured sedimentary bedrock consisting of mudstones, siltstones, and sandstones (Klohn, 1985; Piteau, 1997; SRK 2018; 2019). *In-situ* hydraulic conductivity of the bedrock ranged from 6.0×10^{-6} m/s to 1.0×10^{-10} m/s.

Using the British Columbia Groundwater Wells Database, a search was completed, and 11 water wells were found in the vicinity of the mining operations. Nine domestic drinking water wells and two commercial water wells were found to be in the area N-NE of the mine site. Four of the wells are just south of the Telkwa River and west of Tenas Creek while the remaining seven (7) wells are east of Goathorn Creek. The range in finished depth of the water wells is 12 to 43 m below ground level (mbgl),

with a range of static head of 5.5 to 39 m below top of casing (btc), and an estimated yield range from 15 to 114 L/min.

Table 2.1 Record of hydrogeological investigations and *in-situ* testing.

Location and Geology	Hydrogeological Instrumentation	Groundwater Flow and Piezometric Surface	*In-Situ* Hydraulic Conductivity (K) and Linear Flow Velocity (V)
Telka Site (Klohn, 1985) Variable thicknesses of glacial till and gravel overlying sequences of sandstones, siltstones, mudstones, and coal. Bedrock dips 15-20 degrees to the east and is structurally dominated by several N-S trending reverse faults and normal faults which trend N-S and EW. Bedrock is of low permeability and contains no stratigraphically definable aquifers. The groundwater table is at or close to ground surface for much of the eastern part of the site. Breccia filled fault zones are expected to be significant conductors of groundwater.	16 piezometers installed (*none of the piezometers are still functional)	23 rural households within 3 km of the mine area obtain their domestic water supplies from groundwater, either by dug wells (2 to 6 m depth) or by drilled wells (less than 50 m depth) Domestic well records indicate that groundwater in the area is at about 12.5 m depth within a gravel layer.	Coefficient of permeability, Coal: 5×10^{-7} to 5×10^{-9} m/s Siltstone, Mudstone Sandstone: 2×10^{-7} to 1×10^{-10} m/s Recharge was estimated as 3% of annual precipitation based on the estimated groundwater flux and a value for hydraulic conductivity derived from the packer tests.
Tenas Pit (Piteau, 1997) Telkwa coal lease is underlain by coal-bearing sedimentary sequence comprising siltstone, sandstone, mudstone, and shale strata of the Lower Cretaceous age Skeena Group (Units 1-4). Economic coal seams in Unit 1 – 120 mm thick sequence of interbedded coal and sedimentary rocks. Faulting is near vertical, one group strikes ~NW/SE and other group strikes ~NE/SW. Few E/W striking faults. Surficial deposits are primarily till ranging from sandy silt to silty clay with minor gravel with range in thickness from less than 3 m to more than 10 m.	4 piezometers within coal seam #1 in 1995 5 piezometers in the major coal seams at three new locations in 1996	NE direction with horizontal hydraulic gradient of ~0.1. Flowing artesian conditions exist in all but 3 piezometers completed in coal seam #1.	K range of 2.1×10^{-8} to 6.0×10^{-6} m/s Average V is 115 m/year but does not consider local fault or fracture zones. V in the range of 10 to 250 m/year may be expected.

Location and Geology	Hydrogeological Instrumentation	Groundwater Flow and Piezometric Surface	*In-Situ* Hydraulic Conductivity (K) and Linear Flow Velocity (V)
Waste Dumps (Piteau, 1997) Waste dump sites underlain by till from 3.75 - 13.5 m thick. Thinnest till blanket is deposited directly on the bedrock surface and thickest till deposit overlies outwash sediments. East side of Tenas pit, thin 6.0 m till overlies permeable sands and gravels. Where overburden is more than 10 m thick, bedrock is overlain by high permeability sand and gravel outwash deposits. The thickest of which (106 m) is in the NW corner of the Tenas waste dump sites where a buried channel (clays, sands, and gravels) exists where the depth to bedrock exceeds 117 m. Bedrock from 4.6 - 117 m consists of either volcanic ash or interbedded sequences of siltstone and mudstone with occasional sandstone.	11 holes drilled at 9 locations	Interpreted to follow topography within surficial sediments between 0.5 - 2.0 m. Depending on location, shallow groundwater flow will either be in a northwesterly or northeasterly direction towards Tenas Creek or Four Creek. At one piezometer nest, strong downward vertical gradients indicative of groundwater recharge conditions exist between upper and lower water-bearing deposits. Due to upland topography of the waste dump sites, groundwater recharge conditions are expected to prevail.	Three single well response tests indicated K of the upper water-bearing till deposit to be in the range of 2.8×10^{-9} to 7.2×10^{-7} m/s. These values are low and thus vertical infiltration rates through this deposit would similarly be expected to be low.
Pit 3 (Piteau, 1997) Bedrock: alternating sequence of siltstone, mudstone, sandstone, and coal with sporadic volcanic tuffs throughout the sequence. Complex series of sub-parallel, N-S trending reverse faults and N-S, and to a lesser extend E-W, trending normal faults. Bedrock overlain by ~10 - 15 m of silty clay till with minor coarse fragments and sand.	5 piezometers installed at 3 locations in Pit 3. At each location, a piezometer was completed across coal seam #2 A second piezometer was installed across coal seam #4 at two locations.	Within coal units, groundwater flow is interpreted to be in a north to northwesterly direction. Horizontal hydraulic gradient of ~0.04. Depth to water ranged from 7.55 - 36.73 mbgs.	From one single well response test, K of coal seam #2 estimated at 4.3×10^{-10} m/s. From two single well response tests, K of coal seam #4 estimated at 8.5×10^{-7} m/s and 3.7×10^{-6} m/s. Average V in coal seams estimated range 20-100 m/year.
Mine rock dumps and sediment ponds (SRK, 2018)	13 sonic drillholes to depths between 9.0 m and 30.8 m upon reaching bedrock or sufficiently high soil density.	Two sonic piezometers were dry, one had water up to ground level and the last had a depth to water of ~14 m.	-

Location and Geology	Hydrogeological Instrumentation	Groundwater Flow and Piezometric Surface	*In-Situ* Hydraulic Conductivity (K) and Linear Flow Velocity (V)
	4 standpipe piezometers were installed for groundwater monitoring in 2017. 8 diamond drillholes with lengths from 70 m to 213.7 m were drilled. 3 of these drillholes had piezometers installed in them.		
Management ponds, sediment ponds, external soil/rock piles and infrastructure pad (SRK, 2019)	12 sonic drillholes were terminated at depths between 10.7 m and 67.1 m upon reaching bedrock. 12 standpipe piezometers were installed for groundwater monitoring in 2018.	The shallowest groundwater levels were approximately 14 mbgs but the piezometric table was located between 20 m and 40 m within the overburden soils.	-

2.5 Materials

Site-specific material characterization and availability are the two main elements for cover system design. Material selection and strategic placement is a key control on cover system performance and is used to provide a means for functions such as vegetation establishment, erosion control, and drainage where required in the cover system design (MEND, 2004).

Surficial deposits (overburden) within the Project Area are primarily till ranging from sandy silt to silty clay with minor gravel (and less than 5% cobbles and boulders) with a range in thickness over the Tenas Project Area from 4 m to 100 m (SRK, 2018). Recent drilling investigations (SRK, 2018; 2019) of the overburden material are in agreement with historical investigations (Klohn, 1985; Piteau, 1997) except for no sand and gravel outwash deposits in the northwest of the project site reported in Piteau (1997) being encountered in current drill holes (SRK, 2018; 2019). The till surface deposits will be excavated in the mining process and stockpiled for later use in the cover systems or direct placed from mining.

The bedrock in the Tenas Open Pit is of the early Cretaceous-aged Skeena Group and consists of alternating sequences of siltstone, mudstone, sandstone, and conglomerates with inter-bedded, bituminous coal seams (SRK, 2018). In Unit 1 a sedimentary sequence from 50 m to 120 m in thickness is interbedded with Coal Seam 1 (Seamas 1A-1F) with individual thicknesses of 1 m to 3 m (SRK, 2018). To access the inter-bedded coal layers, the bedrock will be excavated becoming mine rock to be placed in lifts and covered with the till material.

Particle size distribution (PSD) data was only available for the overburden till material and no information was available for the mine rock. The overburden material can be grouped into two categories based on the PSD data, a poorly-graded till and a well-graded till. Figure 2.2 shows the range of PSDs for each group based on the testing completed by SRK in 2019 (SRK, 2019). Following completion of sample compaction tests, four till samples were assessed for permeability, the results ranged from 1.04×10^{-7} m/s to 1.18×10^{-10} m/s (SRK, 2018).

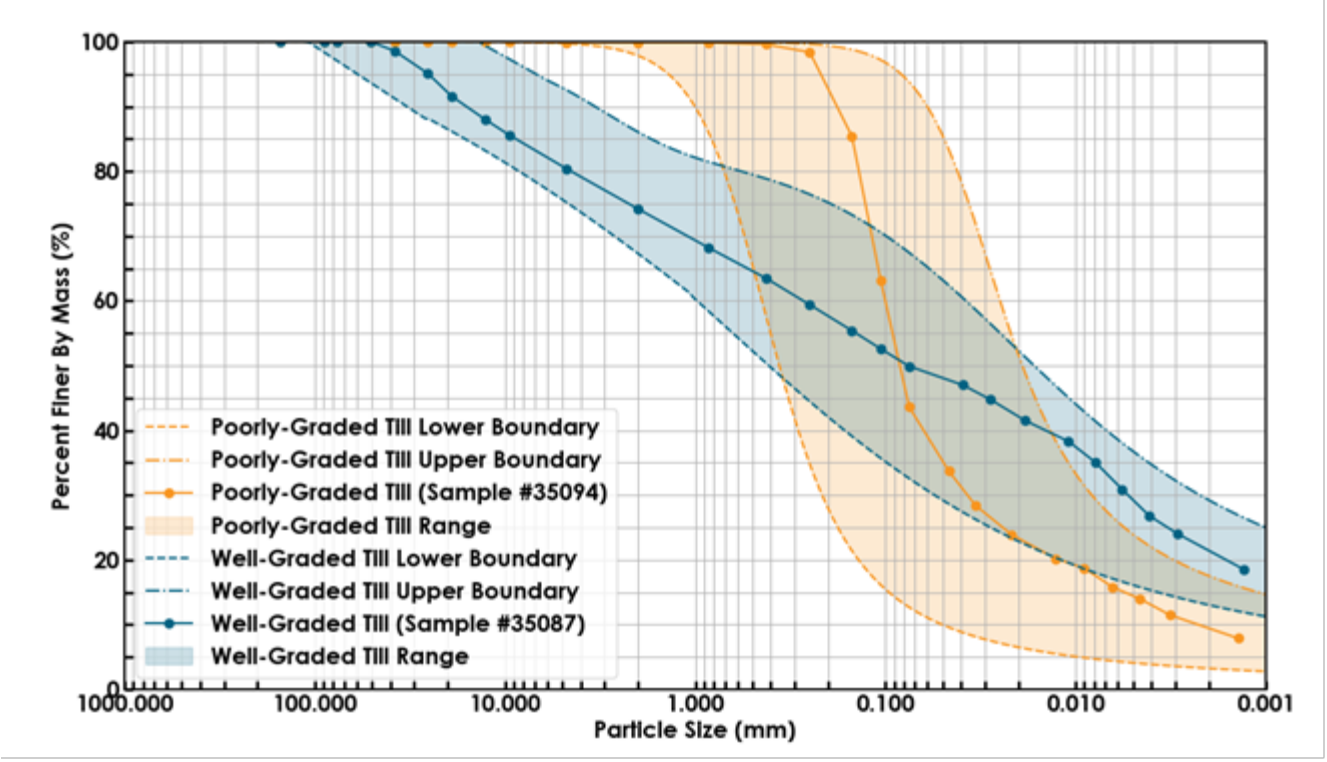

Figure 2.2: Range of PSDs for Poorly-Graded and Well-Graded Till based on SRK (2019).

(adapted from SRK, 2019)

2.6 Vegetation

The Project is located within the Sub-Boreal Spruce (SBS) zone of the biogeoclimatic zones of British Columbia. The dominant coniferous tree species in this zone include hybrid white spruce (hybrid of Engelmann spruce and white spruce), sub-alpine fir, lodgepole pine, and occasionally, black spruce and Douglas-fir (BC Ministry of Forests, 1998). Deciduous species include trembling aspen and paper birch.

2.7 Geochemistry

Non-potentially acid generating mine rock will be used as backfill into the Open Pit. Although sulfide minerals are present (and sulfide oxidation is expected), these materials contain an excess of neutralization potential (at least 2x) relative to the acid potential (AP) and are not expected to generate acidic drainage (Price, 2009). However, sulfide oxidation products will still be generated and transported through the mine rock by contact water. Concentrations of select dissolved trace metals and sulfate will be constrained by secondary mineral precipitation (e.g., gypsum and metal hydroxide phases) and adsorption to iron hydroxides that typically precipitate in circum-neutral mine waters. However, even with these solubility controls, metal loads from pyrite oxidation could still pose a risk to downstream

receptors. A conceptual model of geochemical reactions occurring along a typical flow path within the Tenas NAG mine rock is shown in Figure 2.3.

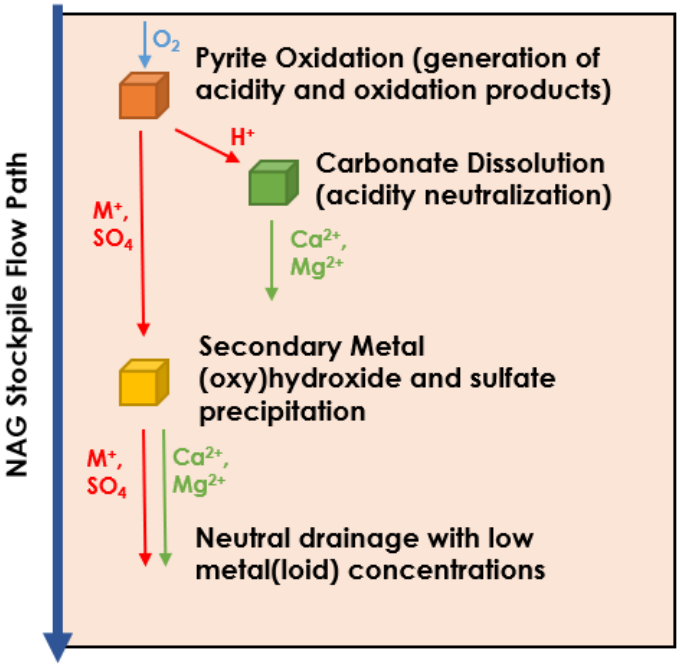

Figure 2.3: Geochemical conceptual model for Tenas NAG mine rock flow path.

Parameters that were elevated above typical crustal concentrations within the Project Area were: arsenic, phosphorus, sulfur, and selenium. Although elevated solid-phase concentrations do not necessarily imply that these species will be mobilized and result in elevated concentrations in contact water, solid-phase metals analysis was completed to flag potential contaminants of concern to evaluate in further geochemical testing.

Current geochemical characterization recommended the use of a neutralization potential ratio (NPR) > 1.60 to classify mine rock as NAG (where, NPR = neutralization potential / acid potential) during verification testing completed during the Operations phase of the Project. For planning and the EAC submission, an NPR cutoff of 2.0 was used to classify mine rock as NAG or PAG, with values > 2.0 considered NAG. This is based on a strong correlation between NP_{XRD} and modified NP following correction for iron carbonates and was developed using calcium and magnesium molar ratios in humidity cell tests (HCTs; SRK, 2022b).

Dolomite-ankerite and calcite are the most abundant carbonate minerals with lesser amounts of siderite in NAG mine rock while PAG mine rock has a higher siderite content. Dolomite-ankerite content ranged from 0.3 to 23.8 wt.% (median = 14.0 wt.%), while calcite ranged from below detection (BD) to 4.4 wt.% (median = 1.4 wt.%). Siderite content ranged from 0.2 to 12.6 wt.% (median = 2.0 wt.%). It is worth noting that siderite does not provide net neutralization to acidity generated from sulfide oxidation. This is because Fe(II) released from siderite dissolution typically oxidizes to Fe(III) which precipitates Fe(III)

hydroxide phases, releasing acidity. Therefore, the bulk of acidity neutralization in the NAG mine rock will come from the dissolution of calcite and dolomite. The primary sulfide mineral in the PAG mine rock is pyrite, which ranges from 0.3 to 2.5 wt.% (median = 0.8 wt.%).

3 DESCRIPTION OF MODELLING PROCESSES

To estimate seepage quantity and quality for the backfilled NAG mine rock in the Open Pit, Okane used the following numerical models and modelling process.

1) ***One-Dimensional (1D) Soil-Plant-Atmosphere (SPA) Models*** using components of the GeoStudio FLOW (Bentley Systems, 2022) modelling suite (namely, SEEP/W and TEMP/W) to simulate the NP rate.

2) ***Two-Dimensional (2D) Oxidation Model*** using the GeoStudio FLOW suite, including SEEP/W, TEMP/W, CTRAW/W, AIR/W, and the Gas Consumption and Exothermic Reactions Add-In Module to evaluate the size and development of suboxic conditions.

3) ***Three-Dimensional (3D) GoldSim Oxidation, Wetting-Up and Draindown Model*** to determine a range for potential seepage and oxygen consumption based on hundreds of realizations of the model, using the GoldSim Monte-Carlo formulation (GoldSim, 2021).

4) The ***Geochemical Model*** using a combination of both a *mechanistic reactive transport model* and a *scale-up geochemical model* to evaluate the evolution of water quality moving through the overburden cover and into the backfilled NAG mine rock.

The source terms from the geochemical model will be provided to SRK to be used in the site-wide water quality model to evaluate the potential effects of key mine facilities on the receiving environment. The following sections describe the numerical models in more detail.

3.1 1D Soil-Plant-Atmosphere Model with GeoStudio SEEP/W and TEMP/W

In combination, SEEP/W and TEMP/W are a 2D finite element model (which can also perform 1D simulations) that predict suction in the material profile in response to climatic forcing (such as evaporation) and lower boundary conditions (such as a water table). A key feature of the software is the ability of the model to predict actual evapotranspiration (AET) based on potential evaporation (PE) and predicted suction, as opposed to the user being required to input these surface flux boundary conditions. The AET rate from the surface material is below the potential rate during prolonged dry periods because the suction, or negative pore water pressure, in the material profile increases as the surface desiccates. In addition, SEEP/W and TEMP/W together form a fully coupled (through the vapour pressure term) heat and mass transfer model, which can predict water vapour movement and the influence of freeze/thaw on hydraulic conditions through reductions in the hydraulic conductivity. The 1D SPA models provide runoff and NP estimates, which are used as inputs in the 2D Oxidation and 3D GoldSim Oxidation, Wetting-Up, and Draindown models.

3.2 2D Oxidation Models

The 2D oxidation modelling was completed using the GeoStudio FLOW suite (SEEP/W, TEMP/W, CTRAN/W, and AIR/W) and the Gas Consumption and Exothermic Reaction Add-In to evaluate the size and development of suboxic zones within the NAG backfill. The models will account for annual material placement and provide estimates of the timing and depth to the suboxic zones, which are used in the 3D GoldSim model, as well as an estimate of cumulative oxygen (O_2) consumption with time, which is used to calibrate and validate the 3D GoldSim results.

3.3 3D GoldSim Oxidation, Wetting-Up and Draindown Model

The 3D model is a wetting-up and drain-down model developed by Okane in GoldSim to simulate the water movement in mine rock based on climate data and material properties. In the model, gravity-driven water flow depends on the NP rate and hydraulic conductivity. The hydraulic conductivity of each layer of mine rock is calculated based on the following formula with measured material properties:

$$k(h) = k_s S_e^l \left[1 - \left(S_e^{\frac{1}{m}}\right)^m\right]^2 \quad (1)$$

where S_e is the effective saturation, k_s is the saturated hydraulic conductivity (LT^{-1}), n and m are van Genuchten's equation parameters, and l is the pore-connectivity parameter. The effective saturation, S_e, within the layer is defined as:

$$S_e = \frac{\theta_w - \theta_{wr}}{\theta_s - \theta_{wr}} \quad (2)$$

where θ_w is the volumetric water content of the layer, θ_{wr} is the residual volumetric water content (L^3/L^3), and θ_s is the saturated volumetric water content (L^3/L^3). The van Genuchten equation parameter m is defined as a function of n as:

$$m = 1 - \frac{1}{n} \quad (3)$$

In the modelling process, hydraulic conductivity is calculated based on the water content of each layer of mine rock. This parameter is then used to calculate the flow rate of water between layers of mine rock. The change in water content due to the placement of new mine rock can also be simulated as part of the hydrogeology model. The Monte-Carlo formulation is used to vary the material properties for each lift of material within an anticipated range to produce a more realistic estimate of overall backfill performance.

The 3D models were extended an additional 50 years to 2150 using stochastic net percolation inputs based on the 1D water balance to ensure that steady state seepage was reached.

3.4 Geochemical Model

The evolution of water quality in the backfilled NAG mine rock was evaluated using a combination of both a mechanistic reactive transport model and a scale-up geochemical model.

The ***Mechanistic Reactive Transport Model*** was constructed with PHREEQC v.3 (Parkhurst and Appelo, 2013) and accounts for geochemical characteristics such as mineralogy, reaction kinetics, transport time, and oxygen conditions of the mine rock. This model incorporates key reactive minerals including sulfides and carbonates, chronology of the NAG mine rock placement, and cover system placement and source control implementation leading to suboxic zone development.

The ***Scale-up Geochemical Model*** was completed to estimate parameters that were not modelled using the Mechanistic Geochemical Model, and generally consist of parameters not directly influenced by sulfide oxidation or carbonate mineral dissolution. Parameter concentrations were calculated based on field barrel leachate quality and scaled-up based on the physicochemical differences between the smaller scale test conditions and expected field conditions of the NAG backfill.

3.5 Model Inputs

3.5.1 Base Case Geometry

The in-pit NAG backfill will be constructed as 120 m wide by 36 m high cells, with a 3 m cover of compacted overburden on the slope of the cell and 1 m of compacted overburden on the plateau of each cell. The cells will be built starting with the face of the slope as a 4 m by 50 m lift / road (1 in Figure 3.1). The overburden and NAG mine rock will be end dumped and compacted in 1.33 m lifts. The second lift will be a 4 m by 39 m lift (2 in Figure 3.1) on top of the first lift, followed by a third lift of 4 m by 28 m (3 in Figure 3.1). The remaining space within the cell will be end dumped as a 12 m high standard dump (4 in Figure 3.1). This process is planned to occur three times per cell, resulting in a 35 m high cell. The last step of each cell is the addition of a 1 m compacted overburden layer, completing the 36 m high cell.

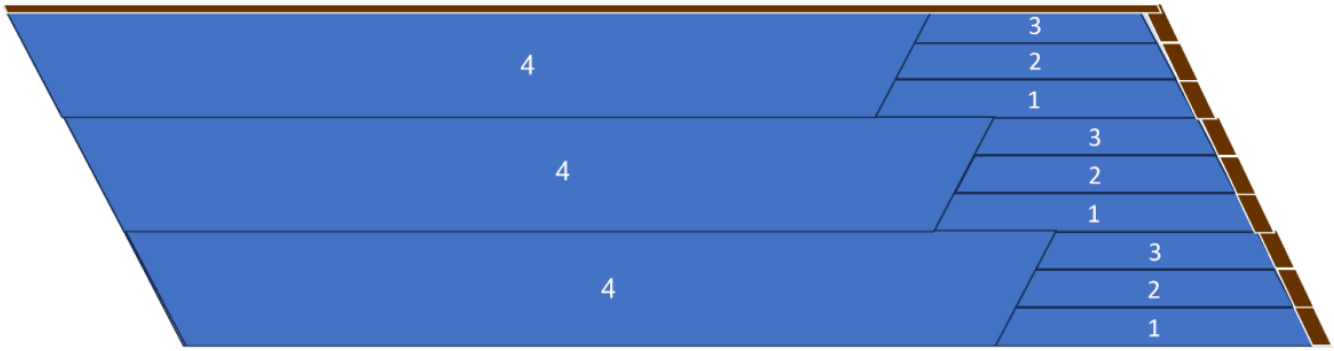

Figure 3.1: Building plan for the cells within the backfilled open pit NAG mine rock landform.

Cells will be stacked and reach an approximate height of three 36 m cells to complete the backfill within the Open Pit, as the bottom and top cells are anticipated to be half height, as shown in Figure 3.2, due to the pit bottom shape and final reclamation goals.

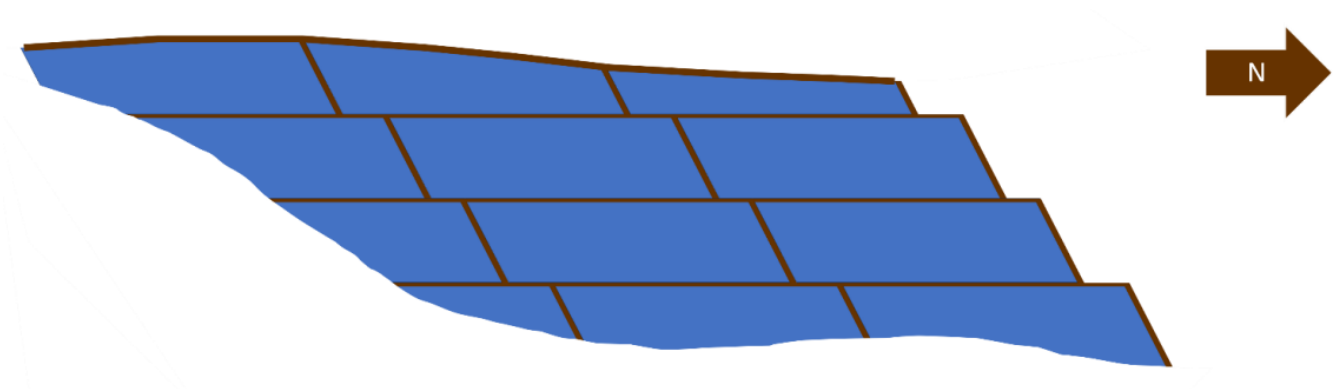

Figure 3.2: Encapsulation plan for NAG in-pit mine rock.

The final cover system on the landform will be 3 m of overburden overlain by approximately 0.3 m of surface soils (topsoil). The 1D models were constructed as 35 m of mine rock with the final cover system at the surface. These models were used to investigate the different material combinations.

A cross-section through the NAG backfill was modelled in 2D to determine the development and extent of the suboxic zone within the backfill. Figure 3.3 shows the approximate location of the cross section while Figure 3.4 shows the 2D geometry that was modelled.

An additional scenario that did not include the internal overburden layers was also modelled. This scenario assumed that the Open Pit would be backfilled following the same procedure as outlined above, but the entire 36 m cell would be composed of mine rock, with only the final cover system being composed of overburden.

Figure 3.3: Plan view of the backfill open pit NAG mine rock showing the strips and approximate location of the projected cross section.

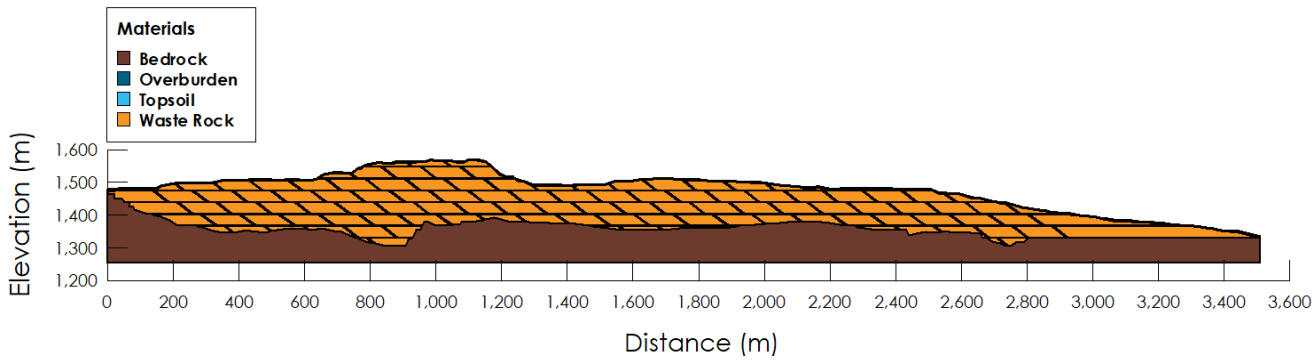

Figure 3.4: Geometry of the project 2D cross section. It should be noted that bedrock refers to bedrock of open pit, waste rock is the NAG mine rock and topsoil includes surface soils.

Within the 3D GoldSim model, the backfilled NAG mine rock was simulated by subdividing its area into 23 main strips, with each strip representing areas with similar timing of cover placement (Figure 3.3). The construction schedule for each strip was assumed based on the filling volumes and timing provided by Telkwa. The following assumptions were made regarding the placement of NAG mine rock for the GoldSim simulations:

- Construction of the NAG backfill is strip dependent, but in general, begins in Year 6 for the main strips and continues until the completion of the Operation phase in Year 21;
- Cover system placement is strip dependent and will be assumed to occur over one year (*e.g.*, cover placement that occurred in Year 8 will be assumed to occur at a uniform rate from January 1 to December 31 of Year 8). Cover system placement is assumed to occur in the year following completion of each strip due to model limitations; and
- Daily NP rate inputs will be derived separately from the 1D GeoStudio model results. In general, daily stochastic inputs will be setup for each day of the year based on the results of the GeoStudio models.

The assumed height of NAG mine rock and overburden in each strip with time, based on the volume of material placed and the surface area of the strip is shown in Figure 3.5. The surface area, total NAG mine rock and overburden volumes, and timing of cover system placement are listed in Table 3.1. For the no internal layers scenario, the internal layer volume was assumed to be NAG mine rock rather than overburden.

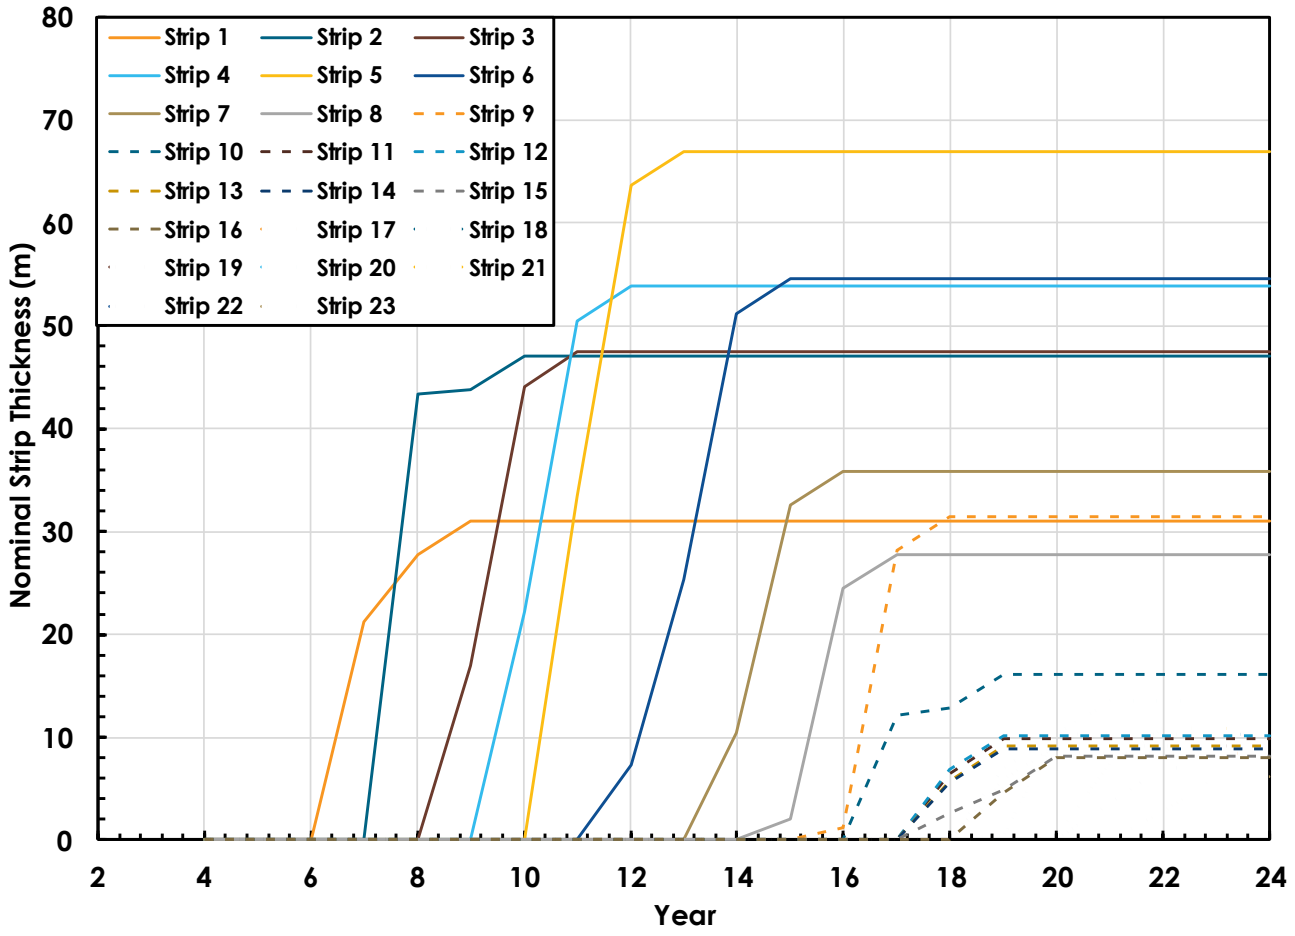

Figure 3.5: Evolution of nominal strip thickness within the GoldSim model for each strip.

Table 3.1: Surface area, volume, and nominal thickness of each strip, along with year of cover system placement.

1 - Includes total NAG mine rock and overburden volumes.

3.5.2 Material Properties

The hydraulic properties or functions required for modelling of overburden and NAG mine rock material are as follows:

- Water retention curve (WRC – volumetric water content versus matric suction): a continuous function relating energy and the state of water, and hence describes the water content of a material as a function of the soil suction, or negative pore-water pressure. It is central to the design of an unsaturated soil system.

- Hydraulic conductivity function (k-function – hydraulic conductivity versus matric suction): a measure of the ability of a soil or rock material to transmit water and is a maximum for saturated soil or rock materials. The saturated hydraulic conductivity (k_{sat}) and unsaturated hydraulic conductivity function are key input parameters to numerical models analyzing hydraulic performance.

For the best results, WRC and k_{sat} should be measured in the laboratory and field for each material of interest. In this case, only particle size distribution (PSD) data was available for the overburden material and no information was available for the NAG mine rock. Two PSDs for the overburden material were used as representative samples for well-graded (sample# 35087) and poorly-graded (sample# 35094) till found in the SRK 2019 field investigations (Figure 2.2).

For the overburden material the WRC (Figure 3.6) and k-function (Figure 3.7) were estimated from the PSD (both well-graded and poorly-graded) using the Fredlund and Xing (1994) pedotransfer functions in SVSOILS™ Software (Plaxis, 2022). The k_{sat} was estimated using Kozeny (1962) with PSD data as the input.

As no lab or field information was available for the NAG mine rock, three proxy materials (mudstone, siltstone, and sandstone) were provided by Okane based on field testing completed at several mine sites. A well-graded mixed material based on core logs consisting of 35% mudstone, 60% siltstone, and 5% sandstone (D. Farmer, 2024, pers. comm.) was also estimated. The WRC and k-functions for the mine rock proxy materials are found in Figure 3.6 and Figure 3.7, respectively.

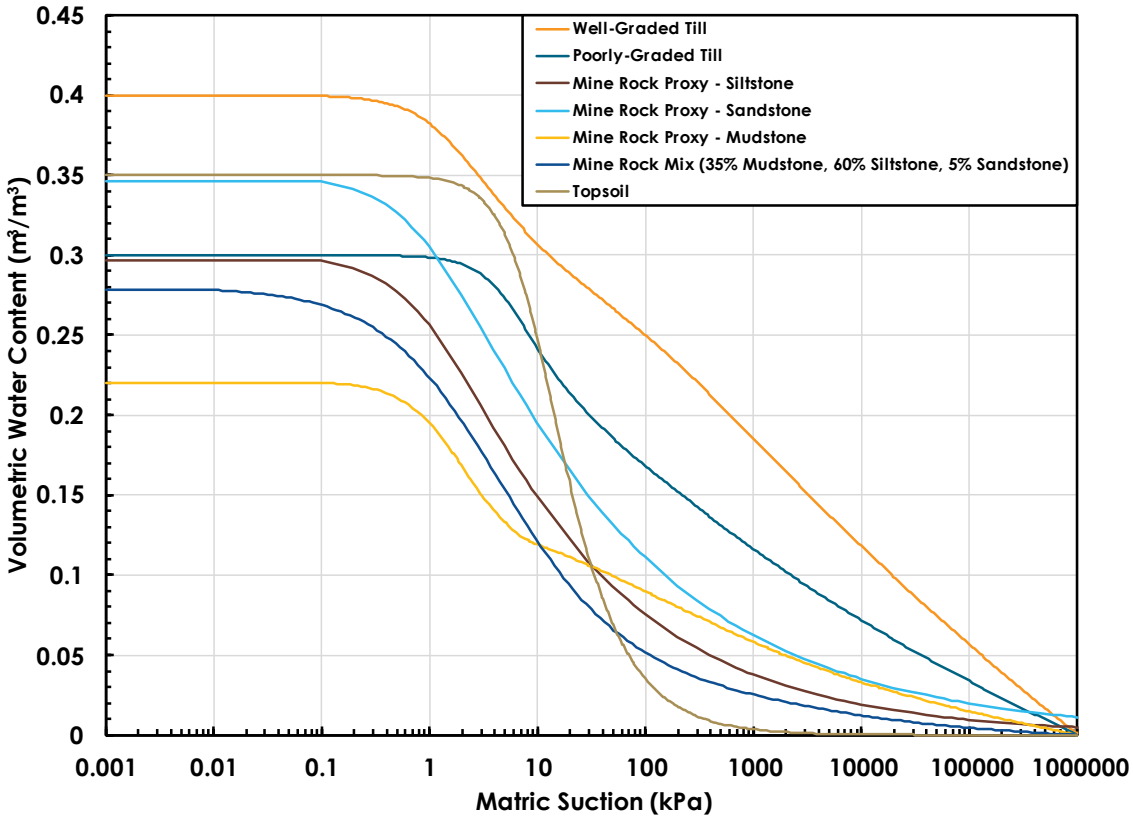

Figure 3.6: Estimated overburden (till) and proxy mine rock water retention curves.

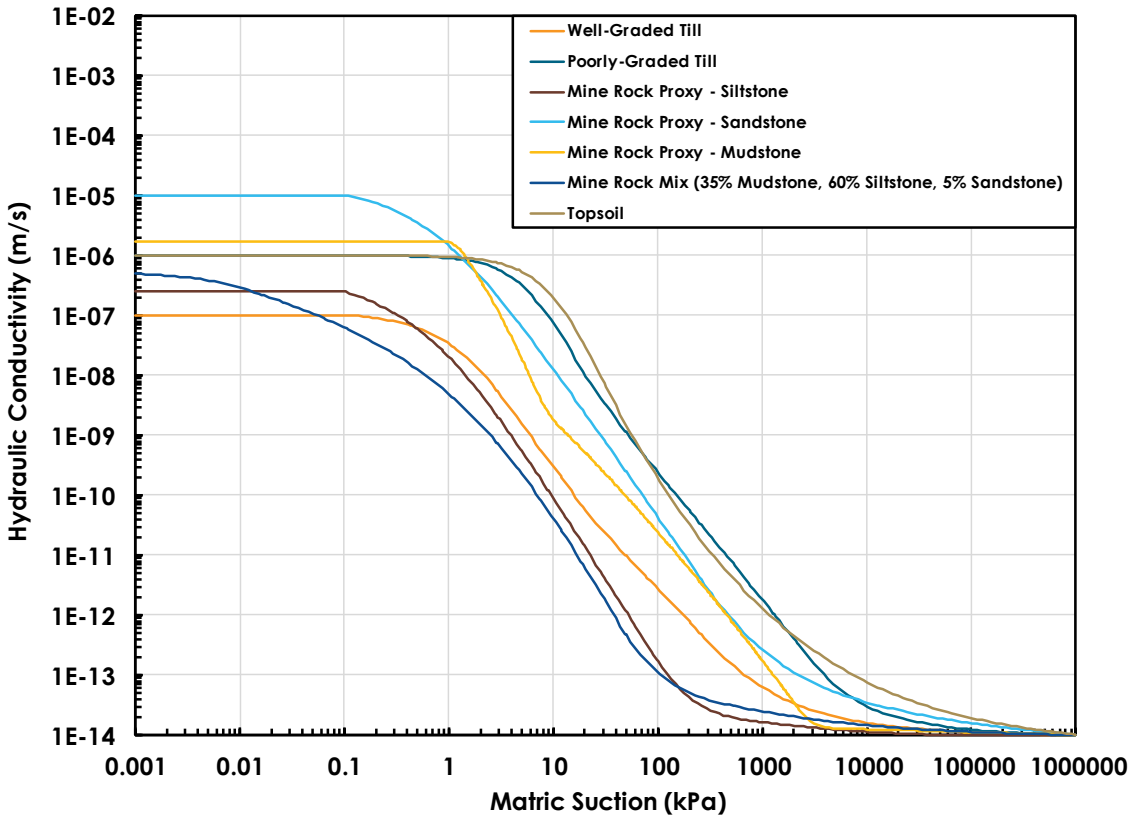

Figure 3.7: Estimated overburden (till) and proxy mine rock k-functions.

3.5.3 Climate Model Inputs

SRK (2022c) developed a project-specific synthetic historical climate database based on transposing regional datasets to the site and adjusting for orographic effects. The historical dataset spans 77 years from 1943 to 2020 and is summarized in Table 3.2.

SRK (2022c) also completed a climate change assessment for the project using the fifth version of the Coupled Model Intercomparison Project (CMIP5) and Representative Concentration Pathway (RCP) 4.5 of the Intergovernmental Panel on Climate Change (IPCC) fifth Assessment Report (AR5) (IPCC, 2014). Monthly rates of changes relative to baseline conditions (1981-2010) were calculated for temperature and precipitation based on the median values of an ensemble of 29 CMIP5 models. Projected climate change effects were evaluated for three consecutive 30-year forecast periods, defined as follows:

- Baseline period from 1981 to 2010 (CMIP5), centred on 1995;
- First forecast period from 2011 to 2040 (CMIP5), centred on 2025;
- Second forecast period from 2041 to 2070 (CMIP5), centred on 2055; and

- Third forecast period from 2071 to 2100 (CMIP5), centred on 2085.

Monthly changes relative to monthly baseline data for RCP4.5 are shown in Table 3.3 for temperature and Table 3.4 for precipitation. A long-term daily dataset (SRK, 2023a) was developed by applying the monthly changes to the average monthly values from the baseline period.

This climate change dataset was used directly as the upper boundary condition in the 1D SPA modelling through the Land-Climate Interaction (LCI) and Surface Energy Balance (SEB) boundary conditions to develop the surface water and energy balance, which was used as the upper boundary conditions in the 2D and 3D models.

Table 3.2 Monthly summary of historical climate database.

Month	Air Temperature (°C)		Precipitation[1] (mm)				Solar Radiation (W/m²)	Relative Humidity (%)	Lake Evaporation (mm)	Wind Speed (m/s)

3.5.4 Vegetation Model Inputs

Vegetation model inputs were based on the SBS bio-geoclimatic zone. Prior to reclamation, no vegetation was assumed. Once areas are reclaimed, vegetation was simulated to re-establish and grow.

To simulate the vegetation re-establishment the following assumptions were made:

- The year after cover system placement, grasses and shrubs are assumed to establish and grow.
- Grasses and shrubs are assumed to be the predominant vegetation for the first five years following cover system placement.
- Forest species are assumed to be the predominant vegetation after the grasses.

3.5.4.1 Rooting Depth and Distribution

The rooting depth and distribution was described by the work of Jackson *et al.* (1996) using the equation:

$$Y = 1 - \beta d \qquad (4)$$

where Y is the cumulative root fraction (a proportion between 0 and 1) from the soil surface to depth d (cm), and β is the fitted 'extinction coefficient', which Jackson *et al.* (1996) estimates as 0.943 for both grassland and boreal forest biomes. Hence, the same rooting depth and distribution (Figure 3.8) were used to represent both grasses and forest growth.

The maximum rooting depth is approximately 1.2 m, with 95% in the top 0.5 m of the cover system. This is like the root characteristics described in Klinka *et al.* (2000) for tree species in the region.

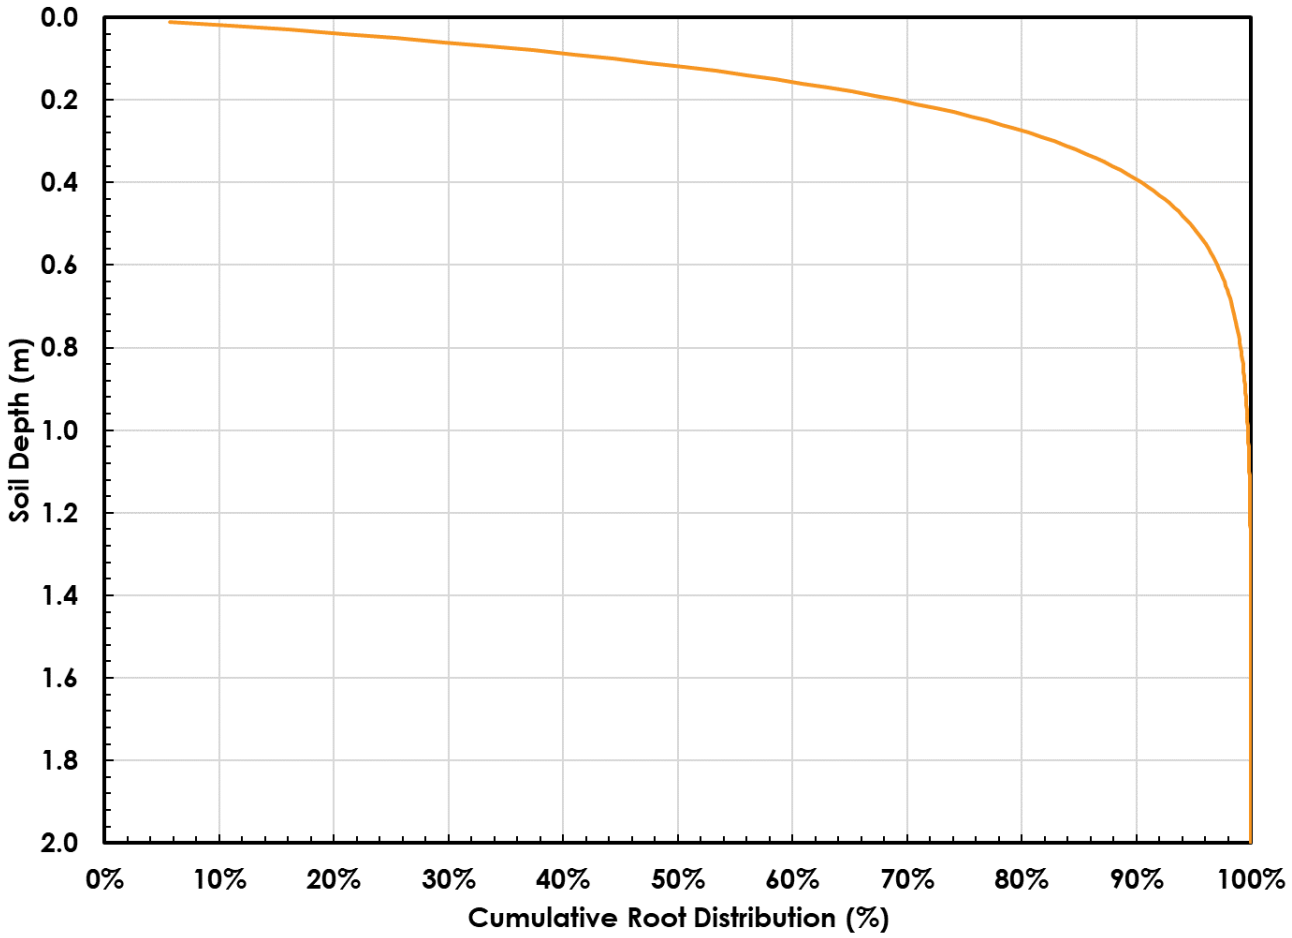

Figure 3.8: Estimated rooting depth and distribution for grasses and forest growth at Tenas Project.

3.5.4.2 Leaf Area Index and Percent Ground Cover

The Leaf Area Index (LAI) for grasses is estimated to be 1.7 with a percent ground cover of 70%. Once forest and understory species establish, LAI is estimated to increase to 2.3 with a percent ground cover of 85%. During the first seven years of vegetation, the LAI was increased annual by 0.3, starting at an LAI of 0.3, to gradually reach the mature forest vegetation LAI of 2.3.

3.5.4.3 Plant Water Limiting Function

Lack of available water and/or high evaporative demands will cause most plants to biologically react by closing stoma, reducing transpiration, and reducing metabolic reactions (Saxton, 1982). Under continued and increasing stress, the plant will reach its permanent wilting point (PWP), at which point transpiration is estimated to cease. The plant water limiting function (PWLF) defines the reduction in transpiration due to increased soil suction conditions. In general, the PWLF is defined to start to reduce at 10 kPa and stop transpiration entirely at a PWP of 1,500 kPa. This function was used to simulate grasses

growing on the cover system. Lopushinsky and Klock (1974) measured the PWLF for conifer species, which produced the PWLF (Figure 3.9). This PWLF was used to simulate forest growth.

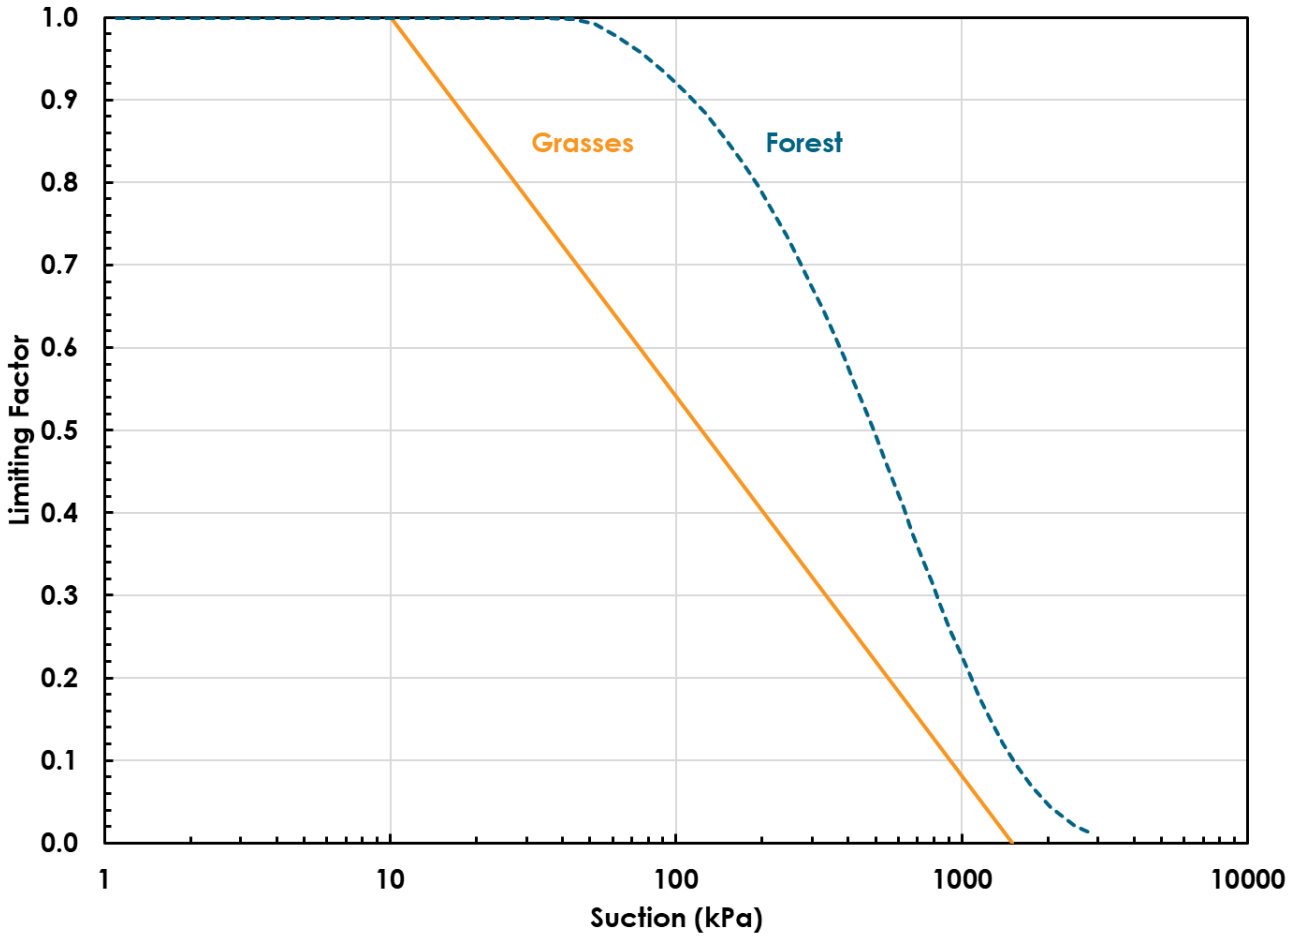

Figure 3.9: PWLFs estimated to simulate grasses and forest growth.

3.5.4.4 Growing Season

To define the growing season, the following assumptions were made:

- The growing season starts once the snowpack is completely melted and mean daily air temperature is above 5°C.
- The growing season ends once the minimum temperature after September 1 drops below 0°C.

3.5.5 Lower Boundary Conditions

The lower boundary condition was assumed to be a unit hydraulic gradient for the 1D simulations. This boundary condition assumes that the movement of water at the depth of the lower boundary is no longer influenced by atmospheric forces and is moving downwards only due to gravity.

3.5.5.1 Initial Conditions

The initial conditions for the 1D SPA model were obtained by running the models twice, using the final conditions of the first simulation as the initial conditions of the second simulation. This is done to remove the subjectivity of the ascribed initial conditions from the model results. The initial conditions of the 2D and 3D models were based on the results of the 1D SPA model.

3.5.6 Geochemical Model

Source terms for the NAG pit backfill were developed using a geochemical model based on the facility specific conceptual model. Source terms were modelled using both mechanistic reactive transport models and geochemical scale-up models. Source terms were developed for three scenarios; two cover system scenarios, a poorly graded till and sandstone mine rock scenario and a well graded till and blended mine rock (60% siltstone, 35% mudstone and 5% sandstone) with internal layers scenario and a third well graded till and blended mine rock (60% siltstone, 35% mudstone and 5% sandstone) without internal layers scenario. Source terms for the NAG pit backfill can be found in Appendix A.

3.5.6.1 Geochemical Model Methodology

Reactive transport models utilized the geochemical code PHREEQC to apply mineralogical kinetics that applicable to NAG mine rock from the Project. The purpose of the reactive transport model was to incorporate mineral kinetics, water flow, and oxygen availability to simulate the evolution of sulfide oxidation rates, metal leaching, and carbonate dissolution simultaneously over a long-term timeframe. Reaction kinetics were calibrated to NAG mine rock barrel tests that are ongoing at the Tenas site (SRK, 2022b). The geochemical scale-up model utilized NAG barrel tests from the Tenas project to calculate loading rates of parameters that are not strongly influenced by sulfide oxidation and carbonate dissolution. Source terms of these parameters were scaled up to conditions representative of the NAG backfill.

Parameters that were modelled via the reactive transport model included pH, alkalinity, SO_4, Al, Ag, As, Ca, Co, Cr, Cd, Cu, Fe, Hg, Mg, Mn, Na, Ni, Pb, Si, Sr, Sn, U, V, Zn, NO_3, NH_3, and NO_2. The mechanistic reactive transport model was developed in two phases:

- ***Phase 1*** – The reactive transport model was developed and calibrated using mineralogical data and barrel test leachate data for representative NAG mine rock.

- ***Phase 2*** – The calibrated reactive transport model for the barrel test was scaled to field conditions by adjusting for the differences in hydrology, temperature, and mass of the reactive particle size fraction (< 6.35 mm in the barrel tests) between the barrel tests and full-scale conditions.

Parameters not incorporated into the reactive transport model were estimated using a geochemical scale-up model. This model was developed by scaling up barrel test production rates by using facility- and site-specific adjustment factors to obtain representative weathering rates. Parameters incorporated in this model included Ba, B, Be, Li, K, P, Si, Sr, Ti, and Zr. Adjustment to full scale conditions was completed by applying scaling factors for reactive particle size, and water contact.

3.5.6.2 Model Development

Reactive transport models were developed for the B1 and B2 barrel tests combined and for the B7 barrel test. The B1 and B2 were combined as these barrels were constructed using the same NAG mine rock samples while the B7 barrel test used different NAG mine rock samples.

Mineralogical analyses for several samples used in the barrel tests reported a single mass for the dolomite-ankerite phase while other samples reported a unique mass for both dolomite and ankerite. Therefore, for modelling purposes it was assumed that if dolomite-ankerite was reported, 50% of this mass was dolomite and the other 50% was ankerite. The reactive mineralogy modelled in the NAG barrel tests is summarized in Table 3.5.

Table 3.5: Summary of reactive minerology in NAG mine rock barrel tests (from SRK, 2022b).

Mineral Name	Unit	B1 and B2	B7	Median NAG Mine Rock
Calcite	wt.%	2.3	0.5	1.4
Siderite	wt.%	7.3	7.8	2.0
Dolomite	wt.%	8.9	8.0	6.9
Ankerite	wt.%	7.9	3.4	0.4
Pyrite	wt.%	4.6	2.0	0.8

Metal leaching was assumed to be predominantly associated with pyrite oxidation. Therefore, metal(loid)s were added to the pyrite mineral phase in PHREEQC based on the molar ratio of respective metals to SO_4 in barrel test leachates (Table 3.6). Divalent cationic metals were assumed to substitute for Fe, while anionic metals were assumed to substitute for S in the pyrite structure. This enabled the release of metals commonly associated with pyrite to be closely coupled to the kinetics of pyrite dissolution in the model.

Table 3.6: Molar composition of pyrite phase used in the reactive transport model.

Parameter	Molar Composition
Fe	0.9999384
Ni	0.0000177
Co	0.0000051
Cu	0.0000044
Pb	0.0000014
Mn	0.000022
Zn	0.0000097
Se	0.000045
As	0.0000013
S	1.99995

Kinetic rate equations were added to the reactive transport model based on published rate law equations and reaction rate coefficients for both the oxidation of sulfide minerals and the dissolution of carbonate phases (Table 3.7). Due to limited kinetic and thermodynamic data associated with ankerite in literature it was assumed that ankerite had the same thermodynamic and kinetic properties as dolomite in the model.

The hydraulic regime of the reactive transport model of the barrel test followed leachate collection events when leachate volumes were measured. Material properties for the reactive particle size fraction (< 6.35 mm) from the water balance modelling were used and assumed a porosity of 0.35 and degree of saturation of 50%, corresponding to a volumetric water content of 0.175 m^3/m^3 in the barrels.

Table 3.7: Kinetic rate equations for minerals included in the reactive transport model.

Mineral	Rate Equation	Rate Constant, k (mol m^{-2} s^{-1})	Effective Rate Constant, k_{eff} (mol m^{-3} s^{-1})	Reference
Pyrite	$Pyrite\ Rate = k\ x \left(\frac{A}{V}\right)\ x\ [H^+]^{-0.11}\ x\ [O_2]^{0.5}\ x \left(\frac{m}{m_0}\right)^{\frac{2}{3}}$	1.1×10^{-10}	-	Williamson and Rimstidt, 1994 Xu et al., 1998
Calcite	$Calcite\ Rate = (k_1\ x\ [H^+] + k_2\ x\ [H_2CO_3])\ x \left(\frac{A}{V}\right)\ x \left(\frac{m}{m_0}\right)^{\frac{2}{3}}$	$k_1 = 10^{-0.05}$ $k_2 = 10^{-0.05}$	-	Chou et al., 1989
Dolomite	$Dolomite\ Rate = k\ x \left(\frac{A}{V}\right)\ x\ [H^+]^{0.5}\ x \left(\frac{m}{m_0}\right)^{\frac{2}{3}}$	$10^{-2.59}$	-	Chou et al., 1989
Ankerite	$Ankerite\ Rate = k\ x \left(\frac{A}{V}\right)\ x\ [H^+]^{0.5}\ x \left(\frac{m}{m_0}\right)^{\frac{2}{3}}$	$10^{-2.59}$	-	*
Siderite	$Siderite\ Rate = k_{eff}\ x \left(\frac{m}{m_0}\right)^{\frac{2}{3}}$	-	$10^{-9.52}$	Dresel, 1989

*Ankerite kinetic characteristics were assumed to be similar to dolomite.

3.5.6.3 Calibration

The reactive transport model was calibrated by adjusting mineral-specific surface areas or effective rate coefficients (Table 3.8) such that modelled barrel test results were comparable to the median leachate concentration of the barrel tests. A separate model was calibrated for the B1 and B2 barrel tests together and another model was calibrated to the B7 barrel test.

Substantial cation exchange between Na, Ca, and Mg was observed in the barrel tests. Carbonate dissolution releases Ca^{2+} and Mg^{2+} that subsequently exchange for Na^{+} from surface sites of the host rock (likely associated with clay minerals). The resulting leachate from the barrel tests is enriched in Na concentrations. In order to calibrate the reaction rate for carbonate dissolution, Ca and Mg concentrations needed to be back calculated from the Na concentrations in the leachate. It was assumed that all Na was sourced from cation exchange with Ca and Mg. The ratio of Ca/Na exchanged compared to Mg/Na exchanged was calculated based on the ratio of ion exchange coefficients of Ca-Na and Mg-Na exchange pairs (Bruggenwert and Kamphorst, 1982).

Table 3.8: Calibrated values of kinetic rate equation parameters.

Mineral	Calibrated Surface Area/Volume (dm^{-1})		Calibrated Effective Rate Coefficient (mol m^{-3} s^{-1})	
	B1 and B2	B7	B1 and B2	B7
Pyrite	-	-	$10^{-8.585}$	$10^{-8.72}$
Calcite	0.01	0.009	-	-
Dolomite	0.02	0.007	-	-
Ankerite	0.01	0.007	-	-
Siderite	-	-	$10^{-9.523}$	$10^{-9.523}$

Following the calibration of the barrel test scale reactive transport model, there was good agreement between modelled parameter concentrations and measured leachate chemistry from the mine rock barrel tests (Figure 3.10). The average of the calibrated factors for the B1/B2 and B7 models were used in the full-scale reactive transport model.

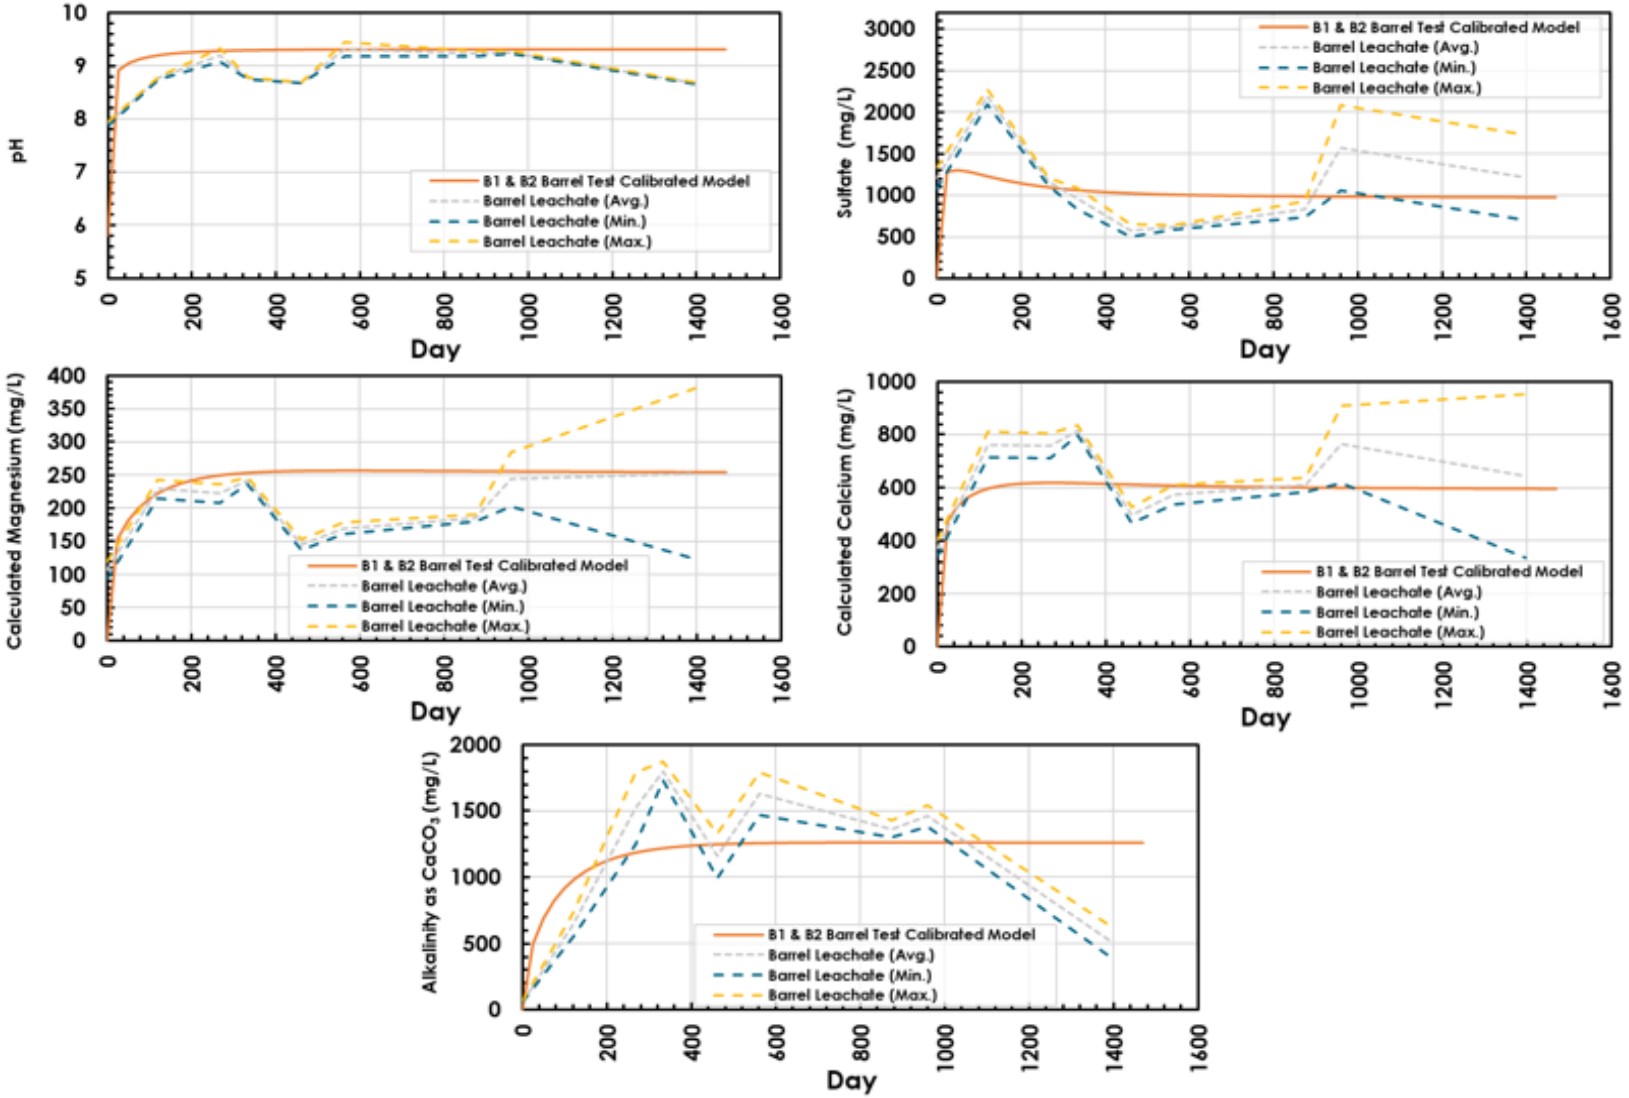

Figure 3.10: Parameter concentrations for the calibrated model versus minimum, maximum, and average B1 and B2 leachate concentrations.

3.5.6.4 Model Scale-Up

Once the geochemical model was calibrated to the field barrel tests, the reactive transport model was scaled up using the nominal height of respective strips (Table 3.1) within the NAG backfill with the final output being stockpile drainage chemistry. GeoStudio oxidation modelling provided stockpile temperature and thickness of both oxic reactive and suboxic non-reactive material. Hydraulic information such as the timing and amount of seepage for the full-scale model was provided by the GoldSim hydrological and seepage models for bare surface and covered conditions.

Temperature Adjustments

The effects of temperature on the literature values for the rate constant of each mineral modelled in the NAG backfill was adjusted using the Arrhenius equation (Equation 4; Gautelier et al., 1999). The temperature adjustment was performed on barrel tests that used an average annual air temperature of 4.9°C. The average internal NAG backfill temperature was estimated to be approximately 3°C based on the GeoStudio oxidation model, and this temperature was used to scale the reaction rates.

$$k_T = k_{25°C}\, x\, A^{\left(\frac{-Ea}{R\Delta T}\right)} \quad (5)$$

Where:

- k_T is the rate constant at temperature, T;
- $k_{25°C}$ is the rate constant at 25°C;
- A is the pre-exponential factor (2.718 s^{-1});
- E_a is the activation energy (kJ);
- R is the molar gas constant (8.314 J K^{-1} mol^{-1}); and
- ΔT is the temperature difference $\left(\frac{1}{T\ (K)} - \frac{1}{298.15\ K}\right)$

The activation energies used for the temperature correction of mineral reaction rates are summarized in Table 3.9. Only pyrite, calcite, and dolomite were adjusted for temperature, while reactivity of siderite was maintained under standard conditions due to a lack of information.

Table 3.9: Activation energies for minerals included in the reactive transport model.

Mineral	Activation Energy (kJ)	Reference
Pyrite	70	Lowson, 1982
Calcite	20.9	Sajwan and Evangelou, 1991
Dolomite	36.1	Herman and White, 1985
Siderite	-	-

3.5.6.5 Reactive Transport Model of the NAG Backfill

Infiltrating Water Chemistry

The chemical signature of the infiltrating water (or net percolation) was assumed to be equal to the water chemistry of a site-specific overburden barrel test because of the use of overburden in the cover system (Table 3.10). Initial NAG backfill porewater was assumed to be similar to the initial water chemistry sampled from the NAG barrel tests. An average from the B1/B2 and B7 tests was used in the full-scale model.

Table 3.10: Reactive transport model infiltrating water and initial NAG backfill porewater composition.

Parameter	Unit	Infiltrating Water Composition	Initial Porewater Composition
pH	-	8.2	7.9
Sulfate (Dissolved)	mg/L	118	1,205
Alkalinity (Total as $CaCO_3$)	mg/L	0.1	106
Chloride (Dissolved)	mg/L	0.25	3.83
Fluoride (Dissolved)	mg/L	0.13	-
Arsenic (Dissolved)	mg/L	0.00078	0.00012
Calcium (Dissolved)	mg/L	45.0	372
Cobalt (Dissolved)	mg/L	0.00016	0.0057
Copper (Dissolved)	mg/L	0.011	0.001
Iron (Dissolved)	mg/L	0.005	0.01
Lead (Dissolved)	mg/L	0.00014	0.0001
Magnesium (Dissolved)	mg/L	26.0	107
Manganese (Dissolved)	mg/L	0.00052	0.034
Nickel (Dissolved)	mg/L	0.00025	0.0074
Potassium (Dissolved)	mg/L	1.6	3.23
Selenium (Dissolved)	mg/L	0.00058	0.11
Sodium (Dissolved)	mg/L	19	512
Zinc (Dissolved)	mg/L	0.0005	0.0043

Parameter	Unit	Infiltrating Water Composition	Initial Porewater Composition
Nitrate (as N)	mg/L	0.44	56.8
Ammonia (Total)	mg/L	0.0088	7.18
Nitrite (as N)	mg/L	0.0039	1.31

Blasting residues from placed mine rock will leach inorganic nitrogen. Initial source terms of N species (NO_3, NO_2, and NH_4) were determined based on the powder factor (0.5 kg/m^3) and proportion of inorganic N produced based on emulsion and ammonium nitrate fuel oil (ANFO) composition (SRK, 2022a). To calculate the mass of residual N in the NAG backfill, the method by Ferguson and Leask (1988) was used and assumed the following:

- 0.9% of N from ANFO and 5.1% of N from the emulsion as available for leaching (Ferguson and Leask, 1988);
- ANFO is 75% ammonium-nitrate and emulsion comprise the remaining 25%; and
- Leachable inorganic N load from explosives will result in:
    - 87% as NO_3-N;
    - 11% as NH_4-N; and
    - 2% as NO_2-N.

Nitrogen species leaching was incorporated into the reactive transport model by using an assumed volumetric water content, the total volume of material placed, and the mass of residual N to calculate an N concentration leaching from the backfill. This methodology was used so that the hydraulic transport time simulated in the reactive transport model could also be applied to N leaching. Nitrogen species concentrations used in the model are shown in Table 3.10.

Mineralogy

The NAG backfill reactive transport models included both reactive primary minerals and secondary minerals. Reactive primary minerals were limited to pyrite, calcite, dolomite, ankerite, and siderite. Additional minerals (e.g., primary silicates) were identified in the geochemical characterization program (SRK, 2022b); however, these minerals were assumed to be kinetically insignificant during the modelled time scale due to the neutral pH of the NAG backfill.

Elevated concentrations of dissolved metals under neutral pH conditions can result in the precipitation of secondary minerals. Secondary mineral precipitation was incorporated into the final reactive transport and geochemical scale-up model results by completing equilibrium modelling on the source terms. Minerals applied in the equilibrium modelling step were generally consistent with those used in the

SRK (2022a) (Table 3.11). Surface adsorption reactions were not included in the model because it was assumed that adsorption was accounted for in the barrel test leachate chemistry, therefore, the pyrite stoichiometric composition used in the model.

Table 3.11: Model equilibrium phases.

Phase	Empirical Formula	Phase	Empirical Formula
Aluminum Hydroxysulfate	$Al_4(OH)_{10}SO_4$	Ferrihydrite	$Fe(OH)_3$
Amorphous Aluminum Hydroxide	$Al(OH)_3$	Goslarite	$ZnSO_4 \cdot 7H_2O$
Azurite	$Cu_3(CO_3)_2(OH)_2$	Gypsum	$CaSO_4 \cdot 2H_2O$
Barite	$BaSO_4$	Lead Molybdenum Oxide	$PbMoO_4$
Birnessite	$MnO_2 \cdot nH_2O$	Malachite	$Cu_2(CO_3)(OH)_2$
Brochantite	$Cu_4SO_4(OH)_6$	Manganite	MnO(OH)
Calcium Molybdenum Oxide	$CaMoO_4$	Melanterite	$FeSO_4 \cdot 7H_2O$
Calcite	$CaCO_3$	Nickel Hydroxide	$Ni(OH)_2$
Chalcanthite	$CuSO_4 \cdot 5H_2O$	Otavite	$CdCO_3$
Carbon Dioxide	$CO_{2(g)}$	Zinc Hydroxide	$Zn(OH)_2$
Copper Hydroxide	$Cu(OH)_2$		

Note: Phases in **BOLD** not included in SRK (2022a).

Flow Transport

Hydrology is an important component of the NAG reactive transport models. The NAG backfill hydrology used results from the GoldSim hydrological and seepage models (Section 3.3). The NAG backfill reactive transport models were split into 23 cells (Figure 3.3), each having different geometries and mine rock storage capacities (Table 3.1).

Material properties of the bulk mine rock in the NAG backfill were included in the full-scale geochemical model but were adjusted to account for only the reactive fraction of the mine rock (assumed to be the -6.35 mm fraction as used in the barrel tests). Flow of water was assumed to be primarily matrix-dominated. Flow calculations for the model assumed the following material properties for the finer fraction:

- Porosity – The porosity of the finer fraction of the NAG backfill was assumed to be 0.4;
- Degree of saturation – The degree of saturation of the finer fraction in NAG backfill at steady-state was 0.61 based on GoldSim modelling; and
- Proportion of reactive mine rock – The -6.35 mm size fraction typically controls the reactivity of mine rock. The NAG backfill was assumed to composed of 20% -6.35 mm particles based on existing material properties.

The adjusted reactive volumetric water content of the facility was calculated to be 0.049 based on these values and was used to determine cell-specific pore volumes in the reactive transport model.

The volume of water entering of the NAG backfill will change once the mine rock is covered. Additionally, this volume will be different based on the cover system scenario modelled. Three hydrological periods were defined in NAG backfill reactive transport models for each of the modelled scenarios, respectively:

1) ***Bare Surface*** – This period represented conditions prior to cover system placement on the cell. During this phase, mine rock is exposed to the atmosphere and infiltration rates are 273 mm/year for the poorly graded till and sandstone scenario (Scenario #1) and 143 mm/year for both the well graded till and mixed mine rock scenario (Scenario #2) and the no internal layers scenario (Scenario #3). The duration of the bare surface period is cell-specific and is dependent on the construction and reclamation schedule.

2) **Covered Grass NP** – This phase represented construction of the closure cover on a cell and occurred for a period of five years as re-vegetation occurs. Once the cover system is placed, both oxygen ingress and NP decrease. Once covered, NP decreases to 197 mm/year in the poorly graded till and sandstone scenario (Scenario #1). Due to differences in runoff between the bare surface and the grass covered surface in the well graded till and mixed mine rock scenarios (Scenarios #2 and #3) NP increased to 148 mm/year.

3) **Covered Forest NP** – This phase represents maturing of vegetation on the constructed cover system and occurred for the remaining model time following the covered grass NP period. As vegetation matures and shifts to forest dominated NP decreases. Covered forest NP was 124 mm/year for the poorly graded till and sandstone scenario (Scenario #1) and 72 mm/year for the well graded till and mixed mine rock scenarios (Scenarios #2 and #3).

Effects of Suboxic Zones

Potential establishment of suboxia within the NAG backfill is a function of limiting re-supply of oxygen from the atmosphere, either laterally across angle of repose slopes of the backfilled mine rock, or vertically across the horizontal surface of the backfilled mine rock. Limiting airflow capacity across the horizontal surfaces can also limit lateral advective gas transport, in the absence of a limitation of the presence of a limitation on airflow capacity on the sloping backfilled surface, depending on the lift height of the backfilled mine rock. Initially, oxygen concentration in the pore-space of the backfilled NAG material will be atmospheric (nominally 20.9% by volume). Sulfide material within the NAG material will consume this oxygen; however, if re-supply of oxygen is limited as discussed previously, then the availability of further sulfide oxidation will be limited, thus creating suboxic conditions within each encapsulated cell. As oxygen decreases, and the geochemical conditions shift from oxic to suboxic, additional biological reactions that are favourable in the absence of oxygen may occur; however, to provide a conservative prediction of the effect of suboxic conditions, these biological reactions were

not included in any modelling. This is a substantively conservative approach given that in suboxic conditions, and provided there is opportunity and hydraulic residence time for denitrification, it is reasonable to postulate that bio-reduction of selenium will also occur (see MEND, 2015). Once suboxic conditions are established, the reactive transport model assumes that pyrite oxidation only occurs in the oxic zone nearer to the surface, while carbonate minerals can still react throughout the entire depth of the cell as their reactivity is not dependent on oxygen availability in the NAG backfill.

Given the geometry of the NAG backfill, and the different cell volumes and placement timing, zones of suboxia will vary based on the location of the cell in the NAG backfill. Cell-specific reactive and suboxic zone thicknesses for all cells were determined from the GeoStudio Oxygen Ingress Model results (Section 4.2). The development of suboxic conditions occurred at depths of roughly 13 m below the cover system in the poorly graded till and sandstone scenario and occurred within the 3.3 m cover system in both the well graded till and mixed mine rock scenarios. In order to remain conservative and capture sulfide oxidation and subsequent reactions occurring in the mine rock mix cover system, a depth to suboxic conditions of 3 m was used in the well graded cover system scenarios. Cell-specific reactive and suboxic zone thicknesses are summarized below in Table 3.12.

Table 3.12: Cell-specific reactive and suboxic zone thicknesses.

Cell	Total Cell Height (m)*	Reactive Zone Thickness (m)		Suboxic Zone Thickness (m)	
		Poorly Graded	Well Graded	Poorly Graded Scenario	Well Graded Scenarios
1	28	13	3	15	25

Construction Schedule

The construction schedules of the NAG backfill will influence timing of seepage quality. Placement of the cover system will limit oxygen ingress and NP into the NAG backfill as well as the maturing of the cover system vegetation. The construction schedule of both the backfill and cover system was simplified to allow for implementation into the reactive transport model. These simplifications and assumptions were:

- All cells are built instantaneously, and the complete height of the cell was available for reaction once it was placed in the model.
- Cover system placement for the backfill is indicated by the construction schedule provided by Telkwa and detailed in Section 3.5.1.
- Once covered, there will be an instantaneous decrease in NP.
- Once forest vegetation is developed (assumed to be five years after cover construction) there will be an instantaneous decrease in NP.
- Once covered, there will be an approximately 15-year period for suboxic conditions to develop. It was assumed there will be an instantaneous shift to suboxic conditions 15 years after cover construction.

Additional NAG Backfill Reactive Transport Model Assumptions

- Mineralogy was homogeneous throughout the NAG backfill and is defined based on the NAG mine rock barrel tests compositions;
- Mine rock placement in the NAG backfill will include mine rock characterized as the average composition from the mine rock barrel tests;

- Cell-specific annual loads (mg/year) were calculated based on the reactive transport concentration outputs and total annual flow volumes for each cell respectively;
- The timing of seepage from each cell of the reactive transport model was based on wetting-up timing from the GoldSim model. A cell was assumed to be wetted-up when total annual seepage from the GoldSim model was greater or equal to 50% of the steady state total annual seepage for that cell. Prior to a cell being wetted-up, parameter concentrations were set to equal the concentration from Year 0 of the reactive transport model. Seepage rates are negligible during the time the cell is wetting up, and therefore load from the cell is also negligible;
- After an initial wetting-up phase, final concentrations for the NAG backfill were calculated using the total annual loads (mg/year) from each cell divided by the total annual seepage rate (L/year);
- Seasonality was not included in the model. A constant NP based on bare surface, covered grass surface, or covered forest surface was assumed for all cells;
- Cell-specific seepage volumes and concentrations were mixed at the base of the NAG backfill based on the modelled seepage rates from the GoldSim model;
- The performance of the cover system remains constant;
- Parameter concentrations below detection limit were assigned values of the detection limit used in the barrel test leachate chemistry reporting;
- During the bare surface period, seepage and porewater is in equilibrium with the atmosphere ($\log(pO_2) = -0.7$ and $\log(pCO_2) = -3.5$); and
- During the cover period, pore water residing in the suboxic zone is in equilibrium with O_2 concentrations of 0.1% ($\log(pO_2) = -3.0$).

3.5.6.6 Geochemical Scale-Up Model

Parameters that were not included in the reactive transport model were modelled using a geochemical scale-up model. The geochemical scale-up model functioned by:

- Developing average loading rates for parameters not included in the reactive transport models using the leachate data from the B1, B2 and B7 barrel tests; and
- Scaling-up the production rates based on material placement, hydraulic properties, and material properties.

Soluble salts can accumulate before kinetic experiments are initiated and result in rapid flushing of constituents. Potentially due to the age of the weathering experiments or variations in collected water volumes it was not entirely apparent if the B2 and B7 barrel tests had fully flushed stored soluble salts; however, loading rates from the last three samples collected were used.

Similar to the reactive transport model, loading rates derived using the barrel leachate data were scaled up based on differences between the barrel test scale and the full backfill scale. The scale up included two scaling factors: particle size and mine rock contact. Temperature scaling factors were not applied as it was assumed that the average temperature in the barrels will be comparable to the full-scale NAG backfill.

Particle Size Factor

The reactive particle sizes of the NAG backfill were assumed to be limited to the < 6.35 mm portion and assumed to be 20% of the bulk mine rock; therefore, the scaling factor for particle size was set to 0.2. This particle size scaling factor was previously used by SRK (2022a) to scale HCT loading rates to field scale.

Contact Factor

The reactivity of the mine rock will be limited to the < 6.35 mm portion; however, only a portion of the seepage will react with this portion given the likely presence of preferential flow paths. A contact factor of 0.5 was used in previous source term development (SRK, 2022a) and was deemed reasonable for the current model.

Geochemical Scale-Up Model Assumptions

The following assumptions were included in the geochemical scale-up model:

- Cell-specific annual loads (mg/year) were calculated based on the annual mass of mine rock for the cell in the given year and the loading rate of the parameter (mg/kg/year). After an initial wetting-up phase, final concentrations for the NAG backfill were calculated using the total annual loads (mg/year) for all cells divided by the total annual seepage rate (L/year);

- The wetting up period for the backfill was estimated as the period of time prior to total annual seepage volumes equalling roughly 50% of steady state annual seepage volumes (roughly 17 years). Seepage concentrations prior to wetting up were set to concentrations calculated for the first year after wetting up;

- Once a cell was fully constructed and wetted-up, the annual loads were assumed to remain constant and estimated parameter concentrations were only influenced by changes in annual seepage rates;

- The seepage of all cells mixed at the base of the NAG backfill;

- Loading rates remained constant and were not affected by changes in mineralogy or kinetic rates over time; and

- Solubility controls were applied by including the geochemical scale-up modelled parameters in the equilibrium modelling discussed in Section 3.5.6.5.

3.5.7 Nitrogen Sensitivity Scenarios

Two additional model sensitivity scenarios were simulated to assess nitrogen source terms under different blasting loss conditions. A high nitrogen source term scenario was run to simulate a scenario where nitrogen losses from blasting are greater than expected. A low nitrogen source term scenario was run to simulate decreased nitrogen losses from blasting resulting from blast hole liners used as a source mitigation.

Nitrogen source term scenarios were modelled by either increasing or decreasing the residual nitrogen available for leaching as calculated by Ferguson & Leask (1988). This in turn increased or decreased the initial pore-water concentration of nitrogen species applied in PHREEQC for the respective nitrogen scenarios (Table 3.13). All other reactive transport model inputs remained the same as in the Well-Graded with No Internal Layers models. The high nitrogen source term scenario represents an increase of 56.25% residual nitrogen. Blasthole liners are assumed to decrease nitrogen losses by 37.5% in the low nitrogen source term scenario (D. Farmer, personal communication, July 15, 2024).

Table 3.13: Initial nitrogen species concentrations in NAG backfill porewater for nitrogen source term scenarios.

Parameter	Unit	Initial Porewater Composition		
		Well-Graded No Internal Layers Scenario	High Nitrogen Scenario	Low Nitrogen Scenario
Nitrate (as N)	mg/L	65	102	41
Ammonia (Total)	mg/L	8.3	13	5.2
Nitrite (as N)	mg/L	1.5	2.4	0.94

4 MODELLING RESULTS AND DISCUSSION

4.1 Water Balance Results

A landform water balance was completed to develop simplified boundary conditions for the 2D GeoStudio oxidation modelling and the 3D GoldSim modelling. A summary of the 1D water balance for the two material combination scenarios is provided in Table 4.1. The well-graded till and mine rock mix material properties and results were also used for the no internal layers scenario.

Table 4.1: Summary of water balance results for the two material combination scenarios.

Scenario	Total Precipitation (mm)	Rainfall (% of PPT)	Snow (% of PPT)	Actual Evapotranspiration (% of PPT)	Runoff (% of PPT)	Sublimation (% of PPT)	Net Percolation (% of PPT)
PG Till and Sandstone (Bare)	649	61%	39%	32%	2%	24%	42%
PG Till and Sandstone (Grass – 5 years)	616	52%	48%	49%	0%	19%	32%
PG Till and Sandstone (Forest – 73 years)	655	61%	39%	57%	3%	21%	19%
WG Till and Mine Rock Mix (Bare)	649	61%	39%	42%	12%	24%	22%
WG Till and Mine Rock Mix (Grass – 5 years)	616	52%	48%	54%	3%	19%	24%
WG Till and Mine Rock Mix (Forest – 73 years)	655	61%	39%	59%	9%	21%	11%
Mine Rock Mix (Bare)	649	61%	39%	28%	28%	21%	22%*

PG Till – Poorly Graded Till; WG Till – Well Graded Till; PPT – Precipitation

* - Surface net infiltration into the bare Mine Rock Mix

An average year of daily net percolation rates for each time period (bare, grass, and forest) were used as inputs in the 2D GeoStudio models and stochastically in the 3D GoldSim model.

4.2 2D GeoStudio Oxidation Model Results

The predicted development of the suboxic zone within the NAG backfill mine rock within the Open Pit with time for the poorly graded till and sandstone mine rock scenario is shown in Figure 4.1. The suboxic zone development for the well graded till and mine rock mix scenario is shown in Figure 4.2, while the suboxic zone development for the scenario with no internal overburden layers is shown in Figure 4.3. The models indicate that the long-term depths to suboxia are, on average, 13 m for the poorly graded till with sandstone mine rock scenario and 3.3 m for the well graded till with the mine rock mix scenario, as well as the no internal overburden layers scenario. The suboxic zone takes approximately 15 years to form in each strip in the poorly graded till with sandstone mine rock scenario. In both the well graded till with the mine rock mix scenario and the no internal layers scenario (using well graded till and mine rock mx material properties), it took approximately 13 years for the suboxic zone to form in each strip. These results were used to estimate the development of the suboxic zone within the 3D GoldSim model.

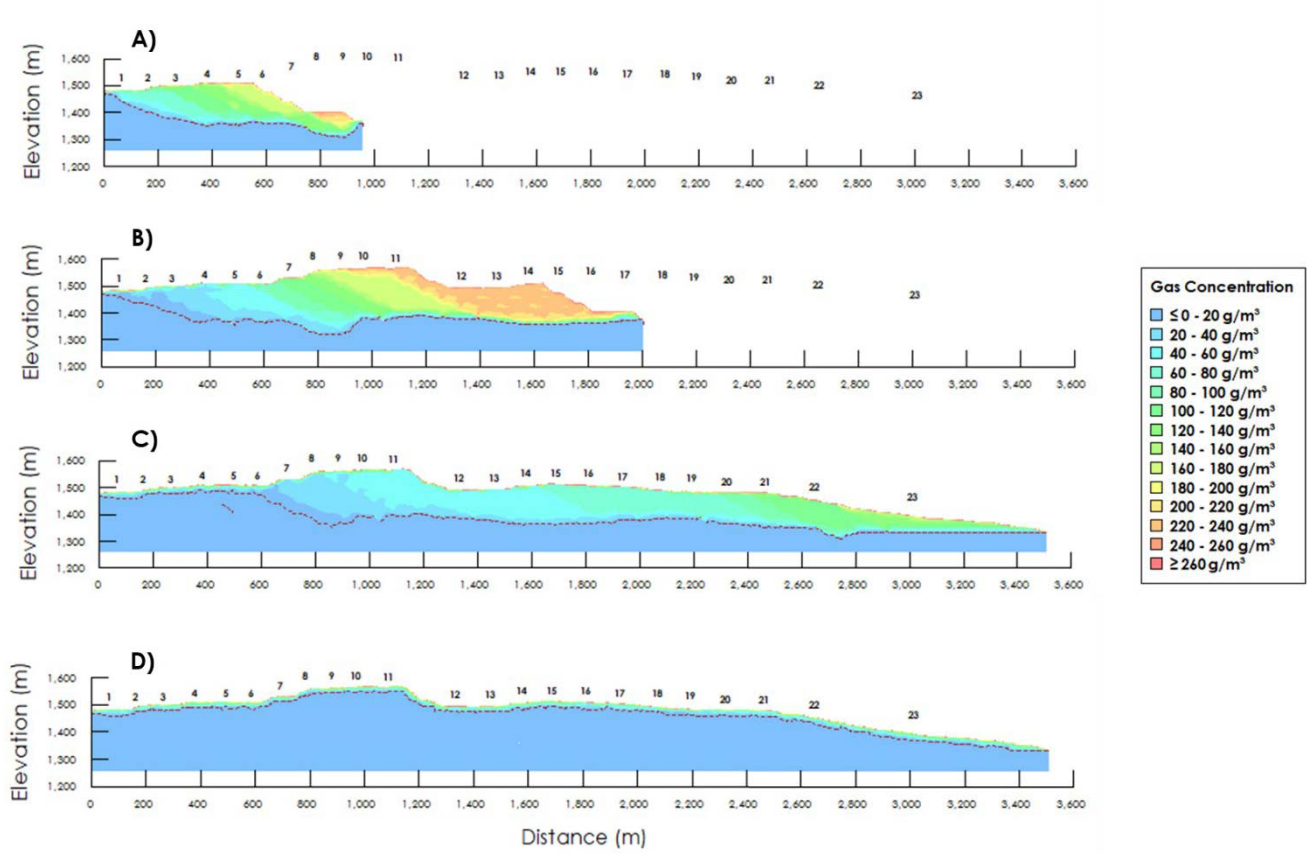

Figure 4.1: Development of suboxic zone for the poorly graded till and sandstone mine rock scenario (outlined by red dashed line in figures, which represents the zone at, or below, an O_2 concentration of 13 g/m³ or 1 vol.%) for the poorly graded till and sandstone mine rock scenario at A) Year 12; B) Year 17; C) Year 23; and d) Year 36/Long Term.

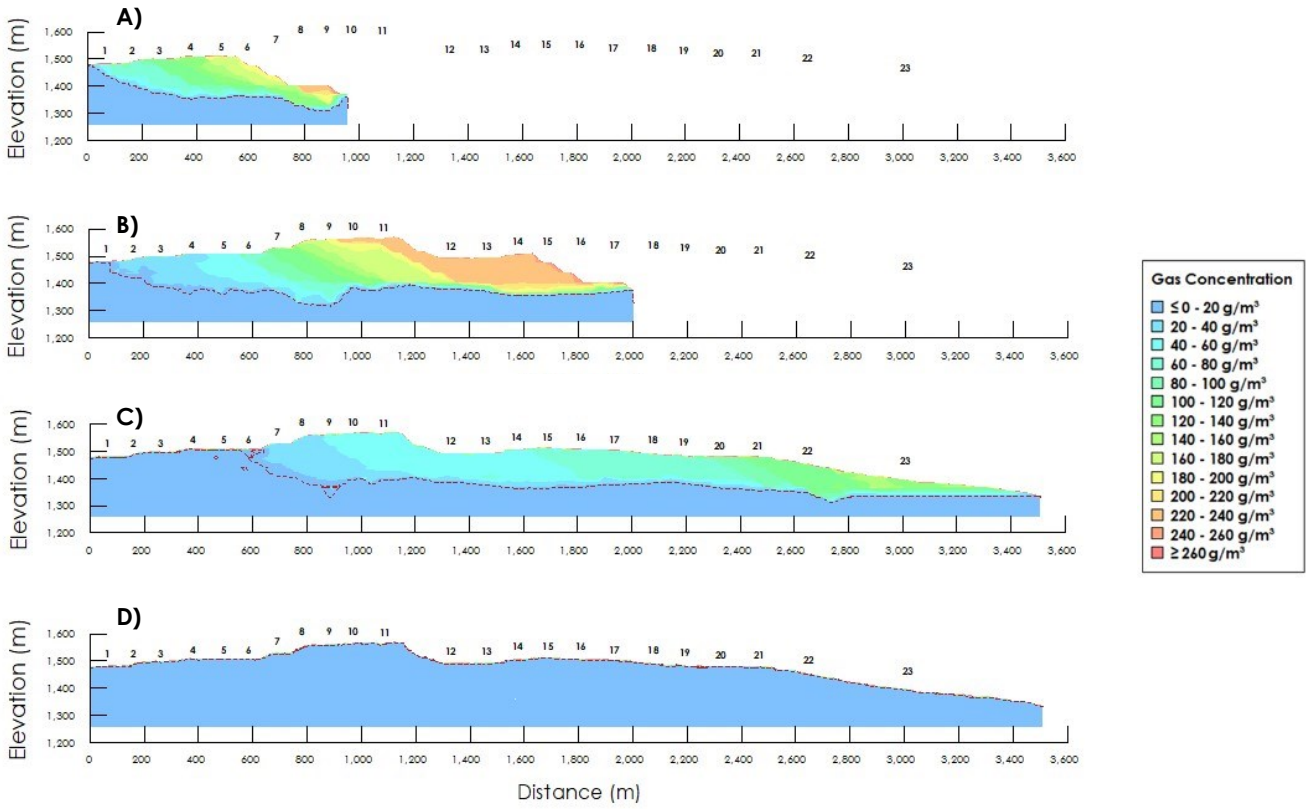

Figure 4.2: Development of suboxic zone (outlined by red dashed line in figures, which represents the zone at, or below, an O_2 concentration of 13 g/m³ or 1 vol.%) for the well graded till and mine rock mix scenario at A) Year 12; B) Year 17; C) Year 23; and d) Year 36/Long Term.

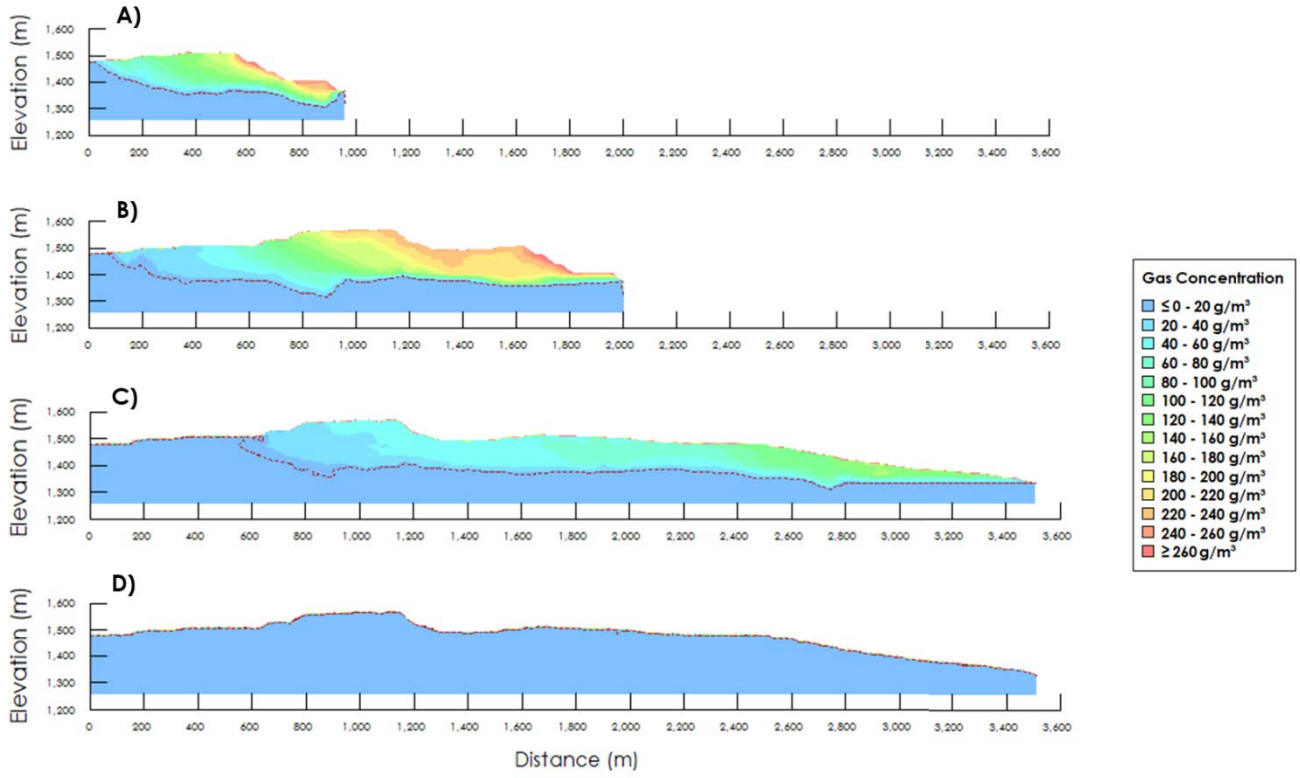

Figure 4.3: Development of suboxic zone (outlined by red dashed line in figures, which represents the zone at, or below, an O_2 concentration of 13 g/m³ or 1 vol.%) for the no internal layers scenario at A) Year 12; B) Year 17; C) Year 23; and d) Year 36/Long Term.

4.3 3D GoldSim Model Results

The 3D GoldSim model was run on calendar time with 2023 representing the first year of placement, or Year 6. The results are therefore presented in calendar time out to 2150, which represents Year 133.

4.3.1 Total Seepage

The total seepage rate of the backfilled NAG mine rock in the Open Pit was simulated in GoldSim for 100 realizations. The mean value, along with the 5th and 95th percentiles of the model results, are plotted in Figure 4.4 for all modelled scenarios. The models predicted long-term stabilized seepage rates from the covered and vegetated backfilled NAG mine rock that were between 31,000 m³/month and 36,000 m³/month for the poorly graded till and sandstone mine rock scenario, and between 14,500 m³/month and 16,000 m³/month for both the well graded till with mine rock mix scenario and the no internal layers scenario. The poorly graded till and sandstone mine rock scenario showed greater variability in monthly seepage rates due to the coarser texture of the material. Prior to cover system placement, the well graded till with mine rock mix scenario differs from the no internal layers scenario

due to the lack of overburden layers, but once the cover system is placed, the two scenarios show almost identical results.

The model results indicate that the backfilled NAG mine rock in the Open Pit will be wetted up, as indicated by the stabilization of the seepage rates, approximately 40 years following completion of construction for the poorly graded till and sandstone mine rock scenario. The finer texture of the material in both the well graded till with mine rock mix scenario and the no internal layers scenario resulted in a longer wetting up period, reaching stabilization approximately 80 years following the completion of construction.

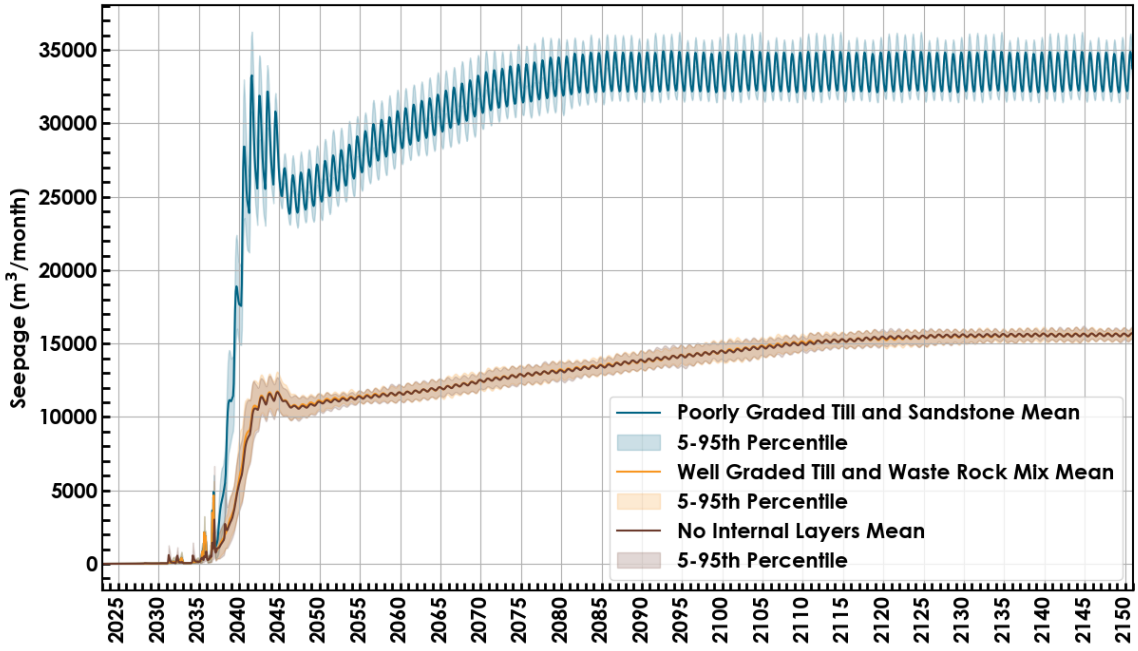

Figure 4.4: Range of seepage rates simulated by the GoldSim model for the backfilled NAG mine rock in the Open Pit for all the scenarios.

4.3.2 Total Storage

The estimated total stored water volume within the backfilled NAG mine rock for the modelled scenarios are shown in Figure 4.5. The modelled water volume increases with mine rock placement during construction before starting to stabilize once construction is complete and the cover system is placed. Similar to the seepage results, the water volume within the backfilled NAG mine rock is estimated to stabilize after approximately 40 years for the poorly graded till and sandstone mine rock scenario and approximately 70-80 years for both the well graded till with mine rock mix scenario and the no internal layers scenario. Once the stored water volume stabilized, very small variations in water volume were predicted, due to the variation in seasonal NP inputs.

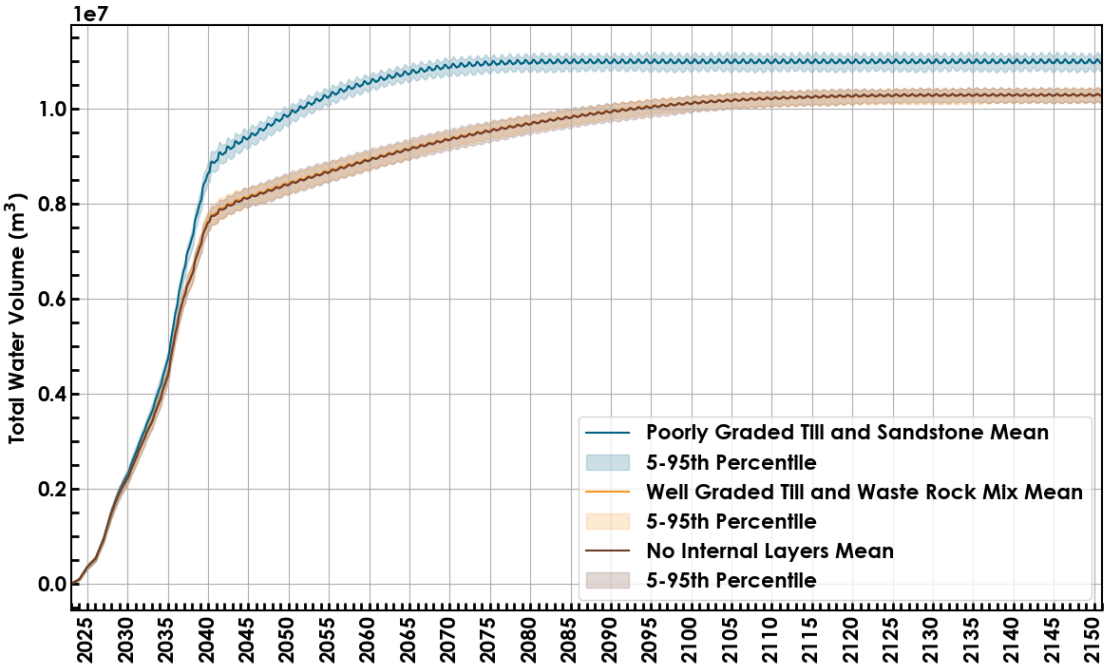

Figure 4.5: Range of total water volume within the backfilled NAG mine rock in the Open Pit simulated by the GoldSim model.

4.3.3 Oxygen Ingress

The range of oxygen ingress from the 3D GoldSim model for all modelled scenarios is presented in Figure 4.6. The well graded till with mine rock mix scenario and the no internal layers scenario both showed a higher long term average oxygen ingress despite having a shallower depth to suboxia. Due to the limitations of the GoldSim model representing each strip as a 1D column, convection is limited to density driven convection (free convection) and oxygen ingress is dominated by diffusion. In this case, with a shallower depth to suboxia, the concentration gradient across the cover system is greater, resulting in a higher diffusive oxygen ingress rate. In the poorly graded till and sandstone mine rock scenario, the depth to suboxia is greater, reducing the concentration gradient across the cover system and lowering the overall diffusive flux. When forced convection (advection) is accounted for, it is likely that the oxygen ingress rate for the poorly graded till and sandstone mine rock scenario would show higher oxygen ingress rates.

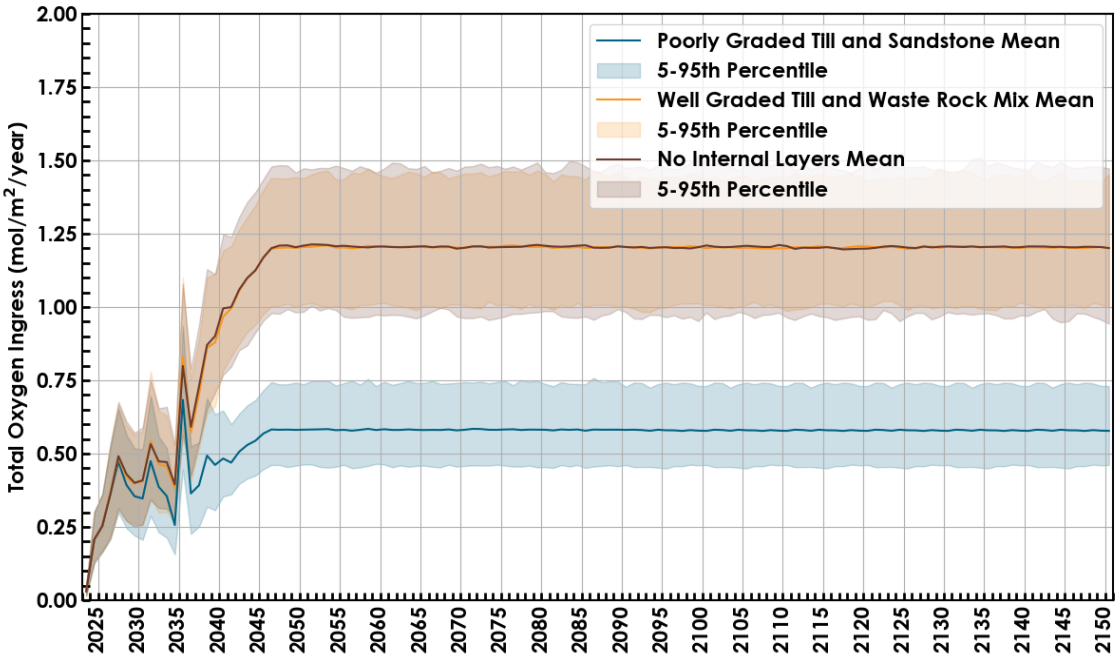

Figure 4.6: Range of oxygen ingress rates simulated by GoldSim for the backfilled NAG mine rock in the Open Pit for all modelled scenarios.

4.4 Geochemical Modelling Results

This section summarizes the results of the geochemical models of the NAG backfill cover scenarios and present a time-series of source terms for the NAG backfill during the bare surface, covered grass surface, and covered forest surface timeframes. Model results of select parameters are presented in Figure 4.7 to Figure 4.11. Tables of source terms and annual loads from the three scenarios of the NAG backfill are provided in Appendix A.

In the three modelled scenarios, the cover system construction decreases NP and limits oxygen ingress into the mine rock within the NAG backfill. Suboxic zones were established in almost half of the cells in the poorly graded till and sandstone mine rock scenario and in all but one cell in the well graded till and mine rock mix scenarios (Section 4.3.3). Sulfide oxidation only occurred in the reactive oxic zones, as a result, loading rates of oxidation products are partly controlled by the amount of suboxic mine rock in the backfill.

In general, concentrations for most modelled parameters were similar between the poorly graded till and sandstone and well graded till and mine rock mix scenarios. While the amount of suboxia increased substantially for the well graded till and mine rock mix scenarios, the volume of water infiltrating the surface of the NAG backfill decreased, resulting is less water available to dilute oxidation products from the limited reactive zone. Despite concentrations remaining similar between the three scenarios, the

annual load exiting the NAG backfill as seepage in both the well graded till and mine rock mix scenarios is roughly half the annual load exiting in the poorly graded till and sandstone scenario.

The onset of seepage from the NAG backfill occurs as cells from the model become fully wetted-up, which begins in approximately 2036. Areas of the backfill that contain smaller thicknesses of mine rock wet up faster than areas with greater thicknesses; therefore, the effects of seepage from thinner cells are observed in the model results faster than the effects from thicker cells. Thicker cells will generally produce poorer water quality than thinner cells because there is a longer pathway for water to accumulate oxidation products (ignoring the effects of suboxic zones).

After the initial wetting-up period and prior to the development of suboxic zones within the models, concentrations of parameters associated with pyrite oxidation (e.g., SO_4, Se, Cu, etc.) generally have an increasing trend. Concentrations stabilize and tend to decrease once suboxic conditions are established. After the onset of seepage, Se concentrations range between 0.03 to 0.07 mg/L, with the onset of lower concentration occurring near the end of the modelled timeframe. Concentrations of Se are trending lower near the end of the modelled timeframe for the well graded till and mine rock mix scenario. Concentrations of SO_4 and Cu are approximately 1,500 mg/L and 0.015 mg/L, respectively, near the end of the modelled timeframes for all three scenarios. Annual loads of parameters related to pyrite oxidation in the well graded till and sandstone scenarios are approximately half of the poorly graded till and mine rock mix scenario. Annual loads are generally similar between the two well graded till and waste rock mix scenarios with the largest differences observed in the last ~20 years of the modelled timeframe.

Nitrate concentrations and loads peak in the initial years that seepage occurs and are controlled by flushing of blast residues that are on the surface of the mine rock. The release of NO_3 (and subsequently NO_2 and NH_4) is spread out over many decades as the transport time is variable in different areas of the backfill depending on the cell thickness.

A slight variation in pH was observed between the modelled scenarios with the well graded till and sandstone scenarios having a slightly higher value. This is likely a result of the longer residence time of water in the suboxic zone of the carbonate-rich mine rock in the well-graded model scenario.

The NAG backfill source terms from the three modelled scenarios are summarized in Table 4.2 and represent the concentrations of parameters at the end of the modelled timeframe (year 2150). The source terms are also compared to source terms developed by SRK (2024). It should be noted that source terms developed by both SRK and Okane utilized NAG field bin data to derive source terms. Differences in source terms are attributed to the implementation of reactive transport modelling and the consideration of changes in net percolation and oxygen ingress into the NAG backfill as a result of the modelled cover systems. In general, the source terms from the current modelling work are lower than the initial SRK source terms. Due to the incorporation of wetting up in the current model, the largest differences in loading rates between both sets of models are observed in the initial 20 years of the model

time frame. Once the modelled loading rates stabilize, mass loads of constituents such as SO_4 and Se range from approximately 50 to 75% lower than the initial SRK loads (Figure 4.12).

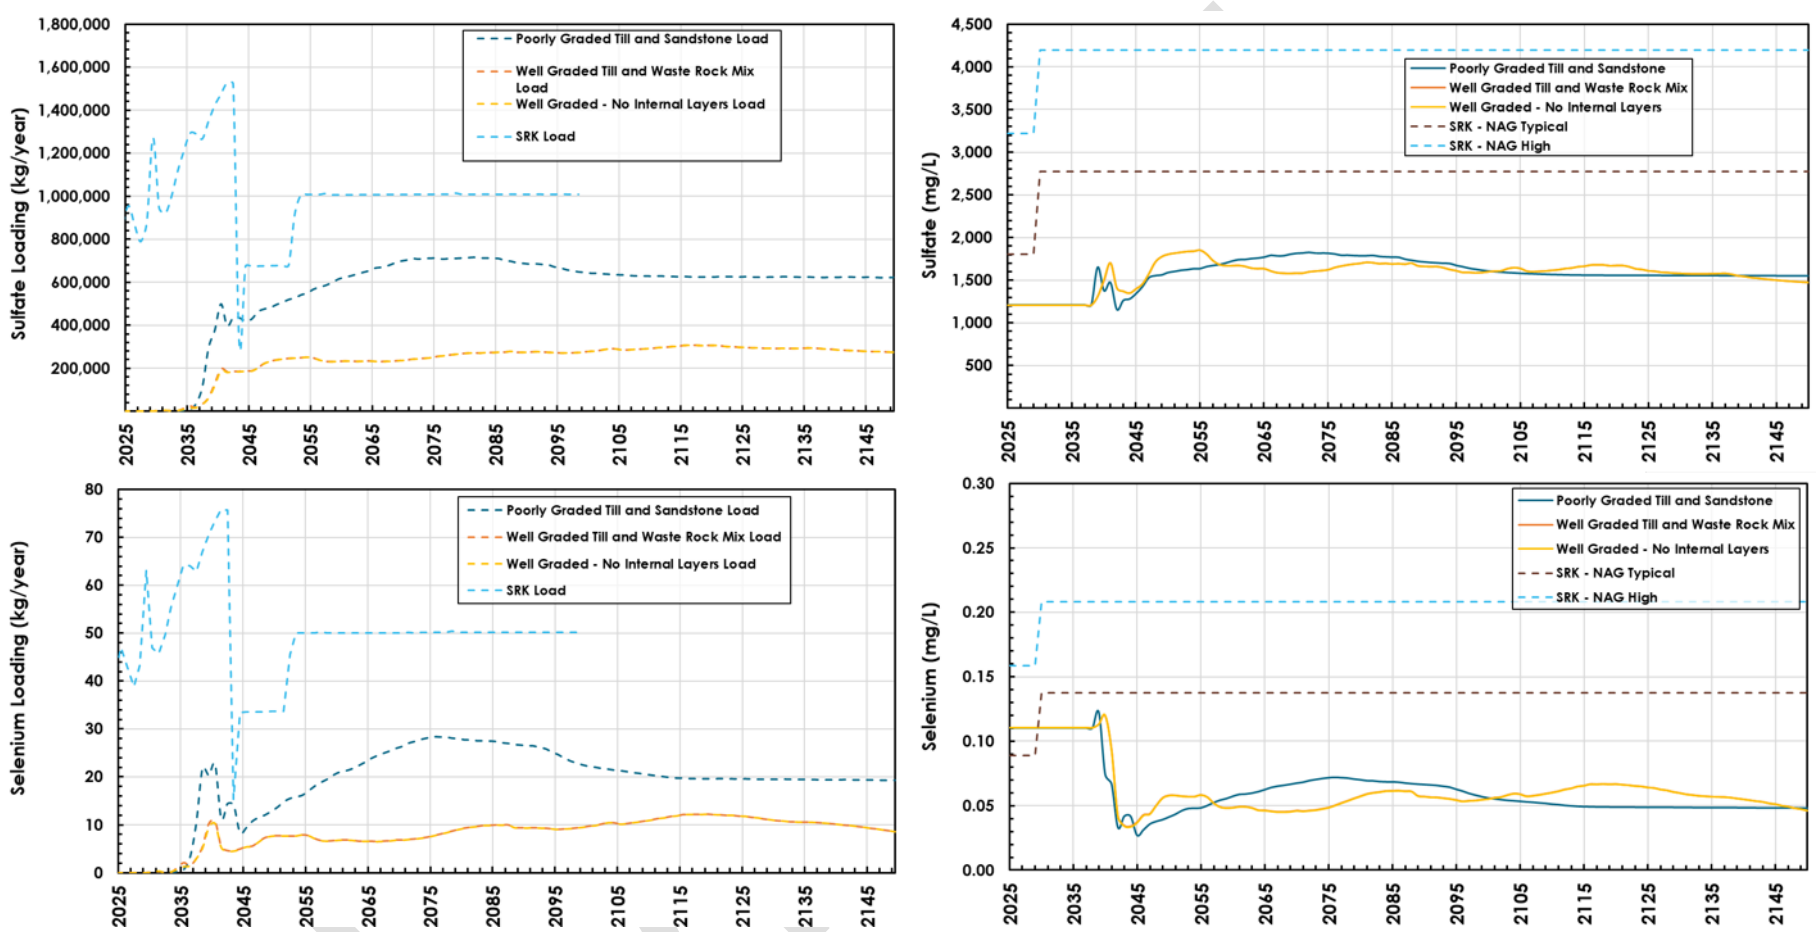

Figure 4.12: Summary of sulfate and selenium NAG backfill source terms and loading rates.

4.4.1 Nitrogen Source Term Scenarios

Nitrogen source terms decreased by 37.5% in the low nitrogen scenario and increased by 56.25% in the high nitrogen scenario throughout the first 15 years of the modelled timeframe as the initial porewater from each cell flushed out (Figure 4.13). Once individual cells began to be fully flushed, there were small variations in the percent change in nitrogen concentrations across sensitivities caused by dilution from cells that had been fully flushed of nitrogen. Overall, the differences in nitrogen source terms were similar to the 37.5% decrease or 56.25% increased applied in the respective sensitivity.

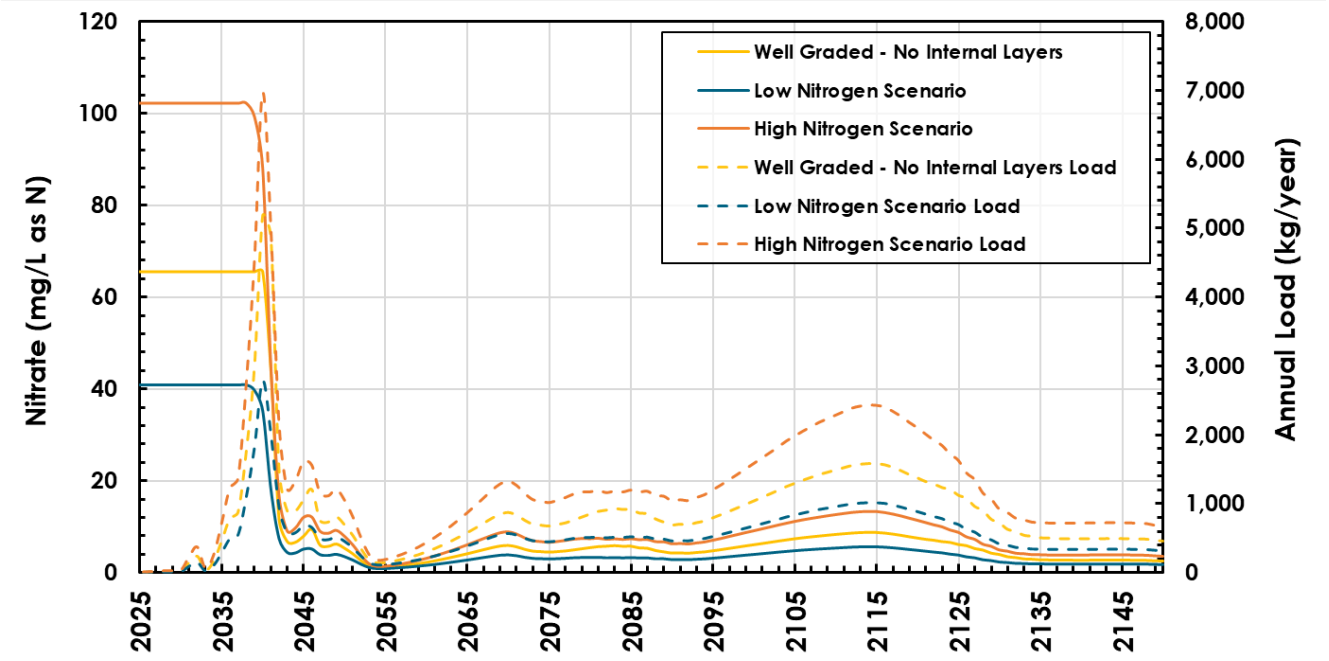

Figure 4.13: Summary of nitrate source terms and loading rates in the well graded – no internal layers scenario and two nitrogen source term scenarios.

5 CONCLUSIONS

The scope of this work was to provide Telkwa support in the development of source terms for three scenarios of backfilled NAG mine rock in lifts using bottom-up construction methodology with overburden covers. The objective of the backfilled design is to limit oxygen and water ingress to minimize the release of potential contaminants of concern such as selenium and sulfate to the receiving environment. Based on the modelling that was completed for this work, the following conclusions are made:

- GoldSim modelling indicates that the backfilled NAG mine rock in the Open Pit will be wetted up approximately 40 years following completion of construction for the poorly graded till and sandstone mine rock scenario. The well graded till with mine rock mix scenario and the no internal layers scenario will be wetted up approximately 80 years following the completion of construction due to the finer texture of material.

- Two-dimensional oxygen models indicate that the long-term depths to suboxia are, on average, 13 m for the poorly graded till and sandstone mine rock scenario and 3.3 m for the well graded till with mine rock mix scenario and the no internal layers scenario. The suboxic zone takes approximately 15 years to form in each strip modelled of the poorly graded till and sandstone mine rock once the cover system has been placed. In both the well graded till with mine rock mix scenario and the no internal layers scenario, the suboxic zone takes approximately 13 years to develop following cover system placement.

- It is likely that the oxygen ingress rate for the poorly graded till and sandstone mine rock scenario would be greater than the well graded till and mine rock mix scenarios.

- In general, concentrations in NAG backfill seepage for most modelled parameters will be similar between the three modelled scenarios.

- The decrease in oxygen ingress and infiltrating water into the NAG backfill for the well graded till and mine rock mix scenarios results in an annual chemical load (mass released per year) decrease of approximately half compared to the poorly graded till and sandstone mine rock scenario.

- As a result, mass loads of dissolved constituents such as selenium and sulfate from the NAG backfill are expected to decrease relative to initial source term and load balance models under the conditions modelled herein.

The NAG backfill source terms from this modelling work will be integrated into the site wide load balance model to quantify the effects of the backfill on water quality around the Tenas project.

Useful Definitions

This list contains definitions of symbols, units, abbreviations, and terminology that may be unfamiliar to the reader.

ANFO	Ammonium Nitrate/fuel oil
BAT	Best available Technology
BC	British Columbia
BMP	Best management practices
CPP	Coal Processing Pond
EAC	Environmental Assessment Certificate
EMP	East Management Pond
EoY	End of Year
GBR	Gravel Bed Reactor
IR	Information Request
MP	Management Pond
MC	Mitigation control
NMP	North Management Pond
Non-PAG	Non-Potentially acid generating (relating to rock)
PAG	Potentially acid generating (relating to rock)
POC	Parameter of Concern
TCP	Tenas Control Pond
TSS	Total Suspended Solids
WMP	West Management Pond
WQG	Water Quality Guidelines

Executive Summary

Telkwa Mining Limited (TML) is proposing to develop the Tenas Coal Project (the Project) located in northwest British Columbia 25 km Southwest of the town of Smithers, BC. In 2022, Telkwa Mining Limited (TML) applied for an Environmental Assessment Certificate (EAC) for the Project, which is currently under review. Throughout the Project definition and design, TML has focused on incorporating features and measures that would mitigate potential effects on water quality of effluent and in the environment downstream of the Project Area.

This report describes the mitigation controls and documents the beneficial effects these measures could have on effluent water quantity and quality as well as changes to water quality and streamflow in creeks and rivers downstream of the Project. The potential efficacy of several additional mitigation controls was evaluated using the Water and Load Balance Model developed for the Project (SRK 2022) with several updates as described below. The Water and Load Balance Model used to evaluate the additional mitigation controls is an updated version of the model issued 2022 (SRK 2022). Updates include:

- Updated source terms and background water quality data including seasonality (collected since 2022).
- Updated climate, flow and climate change estimates based on data collected up to 2023 and newly available climate change models from 2024.
- Updated calculations to estimate load in the creeks through groundwater seepages from the Project, and
- Updated assumptions regarding site operations that affect water and load balance modelling (e.g., date of Tenas Control Pond decommissioning).

Two categories of mitigation controls were considered in this analysis: best management practices (BMPs) and best achievable technologies (BAT). Model results are presented for both categories. However, recommendations are only provided on whether to adopt one or more of the evaluated BMPs in the Final EAC Project Case (2024). The evaluation, ranking, and selection of preferred BATs are addressed in the BAT assessment report, which is included in Appendix H.

Best management practices considered in this analysis are:

- Use of blasthole liners to reduce residual ammonia and nitrate loadings in contact water.
- Addition of freshet water to improve robustness of water cover in the water management ponds to reduce loadings in effluent.
- Increased process water usage in CPP plant, which would reduce the volume of effluent from the site.

Best Achievable Technologies considered in this analysis include:

- Modified liner design in the management and control ponds with Base Case.
- Active/Passive flocculation in sediment ponds with Base Case.
- In-situ Active gravel bed reactors in management ponds with Base Case.

- Active tank-based treatment with Base Case for end-of-pipe effluent (post Tenas Control Pond).

Water quality model results were produced for surface water discharge from Tenas Control Pond, as well as groundwater seepage (groundwater discharge) from the three management ponds (North, East and West) and from Tenas Control Pond. Water quality result for the Receiving Environment were examined for Tenas Creek, Four Creek and Goathorn Creek as these are the closest creeks downstream of the Project and most likely to see an effect from the site discharge.

Model results for the updated EAC Project Case (2024) indicated that no water quality guidelines are exceeded in the receiving environment downstream of the Project, except for dissolved copper in Goathorn Creek, which has naturally elevated background concentrations (that exceed the guideline). In the modelled effluent from the site (surface and groundwater), eleven parameters of concerns (POC) were identified in the different discharges (surface and groundwater) based on the current definition by BC ENV (2024) of 80% of the BC water quality guidelines for freshwater. The assessment of mitigation controls was focused on these POCs.

When compared to the Updated EAC Project case (2024), several mitigation controls affect streamflow (water quantity) in creeks downstream, particularly in Four Creek that naturally has low flows. Modelled reductions in flows in Four Creek were over 12.5% for the Updated EAC Project case as well as for the mitigation controls that included modified liner designs in the management and control ponds as well as the one including the improvement of water cover in management ponds. These mitigation controls lowered the streamflow up to an additional 20% during open water season over the Updated EAC Project Case (2024).

Modelled changes to water quality of effluent and downstream receiving waters, as compared to the Updated EAC Project Case (2024) are summarized in Table 1 below.

Based on the modelled results for the BMP measures, SRK recommends adopting blasthole liners as a mitigation control for the Project as it the only BMP mitigation control that significantly improves the water quality in the surface water discharges and groundwater seepages. Recommendations for BAT measures can be found in the BAT assessment report found in Appendix H.

Table 0-1: Impact of mitigation controls on water quality in effluent and in Receiving Environment

Mitigation Control ID	Positive	Negative	Recommended for Adoption?
Best Management Practices			
MC1: Improve Water Cover	- Reduces most POCs concentrations by a few percent in surface discharge in Tenas Control and North Management Ponds, as well as in groundwater seepage. - Reduces POCs in streams as well to varying degrees in Tenas and Four Creeks with no significant improvements in Goathorn Creek.	- Does not improve concentrations in NMP as it is not targeted.	No
MC4: Increase of process water to CPP	- No notable improvements of discharge water or water quality in the streams.	- none	No
MC5: Blasthole liners	- Reduces nitrogen concentrations in the discharge and the environment between 30 to 40%.	- none	Yes
Best Achievable Technologies (Candidates)			
MC2: Modified Liners in Management and Control Ponds (Option 1)	- Reduces POCs concentrations in Tenas and Four Creeks.	- Worsens TCP surface discharge for a few POCs. - Worsens POCs concentrations in groundwater seepage from TCP and WMP.	See BAT Assessment Report in Appendix H.
MC3: Modified Liners in Management and Control Ponds (Option 2)	- Greatest improvement for a single mitigation control in reducing concentrations of most POCs in Four Creek. - Reduction of POCs concentrations in Tenas Creek (less than in Four Creek).	- Worsens TCP surface discharge for a few POCs (more than MC2). - Worsens POCs concentrations in groundwater seepage from TCP and WMP (more than MC2).	
MC6: Active/Passive Flocculation in TCP	- Reduces total metals concentrations in the surface discharge of TCP (Operations) and Closure)	- No effect on seepage water quality	
MC7: In-situ Active GBR in MPs	- Greatest reduction in selenium, nitrite, and nitrate concentrations in Tenas Creek. - Some improvements in Four Creek water quality for selenium, nitrate, and nitrite. - Reduce maximum concentration of nitrate, selenium, and nitrite at groundwater discharge from both West Management and Tenas Control Ponds.	- none	
MC8: Active treatment post TCP	- Greatest improvement in surface discharge concentration of identified POCs, including nitrate, nitrite, total selenium, dissolved nickel. - Improvement in Goathorn Creek is like MC7 for nitrite, nitrate, and selenium, but targets other POCs as well such as total molybdenum.	- Slightly worsens POCs concentrations in the groundwater seepage for EMP and TCP.	

1 Introduction

1.1 Scope of Work

The Tenas Project (the Project) is a proposed open pit metallurgical coal mine located near Telkwa, British Columbia. In 2022, Telkwa Mining Limited (TML) applied for an Environmental Assessment Certificate (EAC) for the Project, which is currently under review. Throughout the Project definition and design, TML has focused on incorporating features and measures that would mitigate potential effects on water quality within or downstream of the Project Area.

Optimization and review of water quality mitigation controls has continued as part of the EAC application Information Request response process. The potential efficacy of suggested mitigation controls is evaluated using the Water and Load Balance Model developed for the Project (SRK 2022). The purpose of this report is to describe potential water quality mitigation controls and to estimate the performance of such measures in terms of improvements (or changes) to effluent water quantity and quality as well as changes to water quality and streamflow in creeks and rivers downstream of the Project.

1.2 Water and Load Balance Model Updates

SRK Consulting (Canada) Inc. (SRK) prepared the Water and Load Balance Model for the Tenas Project in support of the Environmental Assessment (EA) Application for Telkwa Mining Limited (TML) in 2022, which was based on site data collected up to 2020. Since 2020, the water and load balance has been revised in response to Information Requests from reviewers of the EAC Application and has been updated with new site data collected since 2020.

The following model updates have been completed since the original model report was issued in 2022:

- Updated source terms for the model as described in Appendices A and B, based on barrel data collected since 2019 (Appendix A) and new geochemical modelling based on reduced oxidation and water infiltration in the backfill of the open pit (Appendix B).
- Updated background parameter concentrations to seasonal source terms, overburden source term based on the barrel data, also updated with additional available water quality data collected until 2022.
- Updated synthetic climate time series for the Project Site and updated mean average precipitation for the Project.
- Updated the rainfall-runoff models for each catchment based on additional available flow data (up to 2023), updated water course baseflows, and with new synthetic climate timeseries.
- Updated the climate rate of change based on newly available climate models from 2024 (see Appendix C) as well as new evaporation rates.

Other changes include:

- Updated the method for estimating loadings that report to the receiving environment along groundwater flow paths based on updated groundwater modelling results (Appendix D). The estimates now include an appropriate proportionality between groundwater that originates from the Project and background groundwater/non-effected groundwater.
- Incorporation of progressive reclamation of the embankments, buttresses, and non-potentially acid generating (Non-PAG) backfill in the open pit,
- The decommissioning of Tenas Control Pond occurring in 2048 instead of 2044 as provided in the EAC Project Case (August 2022).
- Various minor changes to operation assumptions, e.g. including an assumed PAG rock water cover that fluctuates between 0.5 to 0.7m while PAG material is being placed in management ponds and/or confirmation of mine plan which affects rock placement on site.

Model results for the Updated EAC Project Case (2024) indicates that the mitigation controls included in the Project description would be protective of the downstream receiving environment and that discharges from the Project would not cause BC water quality guidelines (WQGs) to be exceeded in the creeks and rivers downstream of the Project. The only exceedance modelled in the downstream environment studied within the scope of this report is dissolved copper in Goathorn Creek (prediction node WQSEA1), but this exceedance is caused by background loadings (not by loadings from the Project).

1.3 Potential Additional Water Quality Mitigation Controls

Even though the Tenas Project is not modelled to cause WQG exceedances in the receiving environment, TML has identified additional potential mitigation controls that could further reduce loadings to the receiving environment as summarized by Table 1-1. Mitigation controls listed in Table 1-1 were evaluated using the water and load balance model and the results of the evaluation are presented in Section 3.

Table 1-1: Potential Additional Mitigation Controls

ID	Description	Candidate BAT or BMP
MC1	Improve the robustness of the water covers in the management ponds and reduce loadings from waste rock by increasing the site water inventory during freshet	BMP
MC2	Increase MP liner thickness and reduce seepage to streams (case 7)	BAT
MC3	Increase MP liner thickness and reduce seepage to streams (case 13)	BAT
MC4	Increase of process water intake to CPP plant	BMP
MC5	Addition of blasthole liners	BMP
MC6	Active/Passive flocculation in TCP	BAT
MC7	In-situ GBR Active in MPs	BAT

ID	Description	Candidate BAT or BMP
MC8	Active treatment post TCP	BAT

1.4 BMPs versus BATs

The mitigation controls in Table 1-1 can generally be categorized either as source control measures/best management practices (BMPs) or as potential best achievable technologies (BATs). This distinction is relevant because BC ENV[1] has issued guidance that requires the feasibility and performance of candidate BATs to be evaluated according to the BAT assessment methodology issued in November 2024 (BC ENV 2024), while BMPs must be evaluated separately and prior to a BAT assessment. The distinction between BMPs and BATs are not always well-defined. Table 1-1 indicates which of the two categories each of the mitigation controls belong to according to SRK's interpretation. In general, operational practices that are carried out on a day-to-day basis were considered BMPs, while mitigation controls that require construction of major infrastructure and implementation of water treatment equipment were candidate BATs.

The candidate BATs listed above were evaluated in a BAT assessment, which is included in Appendix H. The BAT assessment was completed in response to Information Requests (IR) 175, 176, 353, 355, and 514 provided by the EAO in their Water IR letter in November of 2022 (SRK 2025). Some of the results of the water and load balance model performance assessment described in this report were used to inform the scoring and ranking of candidate BATs.

As discussed above, BC ENV's BAT assessment guidance stipulates that BMPs should be excluded from consideration in a BAT assessment. However, no guidance on a stand-alone assessment of BMPs is available. Therefore, in the interest of excluding the BMPs from the BAT assessment, the merits of implementing the three BMPs identified were evaluated in this report (Section 4) while the suitability and feasibility of the candidate BATs were evaluated in the BAT assessment report.

[1] January 30th 2025 from BC ENV with review comments on a BAT Assessment summary presentation

2 Candidate Mitigation Controls

Details on candidate source controls, BMPs or BAT mitigation controls are summarized in the following sections.

2.1 Mitigation Control 1: Improve Robustness of the Water Covers of the Management Ponds by adding Freshet Inflows from Channel C02

The concept behind this mitigation control is to reduce potential loadings from rock stored in the management ponds by routing additional water to the management ponds during freshet to improve the robustness of their water covers. A reduction in loadings and an increase in the water inventory would improve the water quality in the management ponds during the Operation phase. This would be achieved by routing water collected in the Potable Water Storage Pond, located upstream of the East Management Pond, into Tenas Control Pond, East Management Pond, and West Management Pond successively during the freshet months of April and May. This additional water would reduce parameter concentrations in the management ponds but would result in more surface water being discharged throughout the remainder of the year.

The Potable Water Storage Pond will collect non-contact water captured in the C02 diversion channel (Figure 2-1). A portion of this water will be pumped to the Potable Water Treatment Plant, while most of the water would discharge via a channel to Four Creek. Before mining, this catchment area reports to Four Creek further downstream than where it will discharge from the Potable Water Storage Pond due to the Project. The discharge channel from the Potable Water Storage Pond into Four Creek is modelled to increase streamflow in the sections of Four Creek upstream of where this catchment naturally discharges. The Potable Water Storage Pond includes an emergency spillway into East Management Pond, which reduces the amount of runoff reporting to Four Creek during storm events equal to or greater than the 1 in 10-year return period event, to minimize the magnitude of high flows to limit potential erosion in Four Creek (SRK 2021).

This mitigation control uses a gate structure in the emergency spillway and in the discharge channel to Four Creek to enable the full flow from the Potable Water Storage Pond to be discharged directly to the East Management Pond. The model assumes this discharge to the East Management Pond would occur each year in April and May, and the remainder of the year water would report to Four Creek. Once the East Management Pond is covered for reclamation, this water would report to the West Management Pond via either a pipeline or a channel across the covered surface. Before East Management Pond gets built, the model assumes that the discharge goes from the gate structure goes to Tenas Control Pond via a pipeline or channel.

Both the East and West Management Ponds will operate with a target maximum and minimum water cover depth over the PAG rock layer during the active PAG rock deposition period. The minimum cover depth of 0.5 m is required to reduce the risk of oxidation of PAG material. The maximum water cover depth triggers a pumping system to limit the storage volume of water in the pond and thereby reduces the risk of erosion on the dam (maximum of 0.7m). The pumping system discharges water to the Tenas

Control Pond, which then discharges to Goathorn Creek. This mitigation control assumes that no pumping from the active management pond would occur during April and May, allowing the water cover depth to temporarily increase beyond 0.7m but remaining below the elevation of the emergency spillway and for pond water to mix with the non-contact water inflows from the Potable Water Storage Pond. The model assumes that pumping is reactivated in June, and the water cover depth is returned to its target level through the remainder of the open-water season.

Figure 2-1 shows the C02 channel and the discharge direction under Mitigation Control 1.

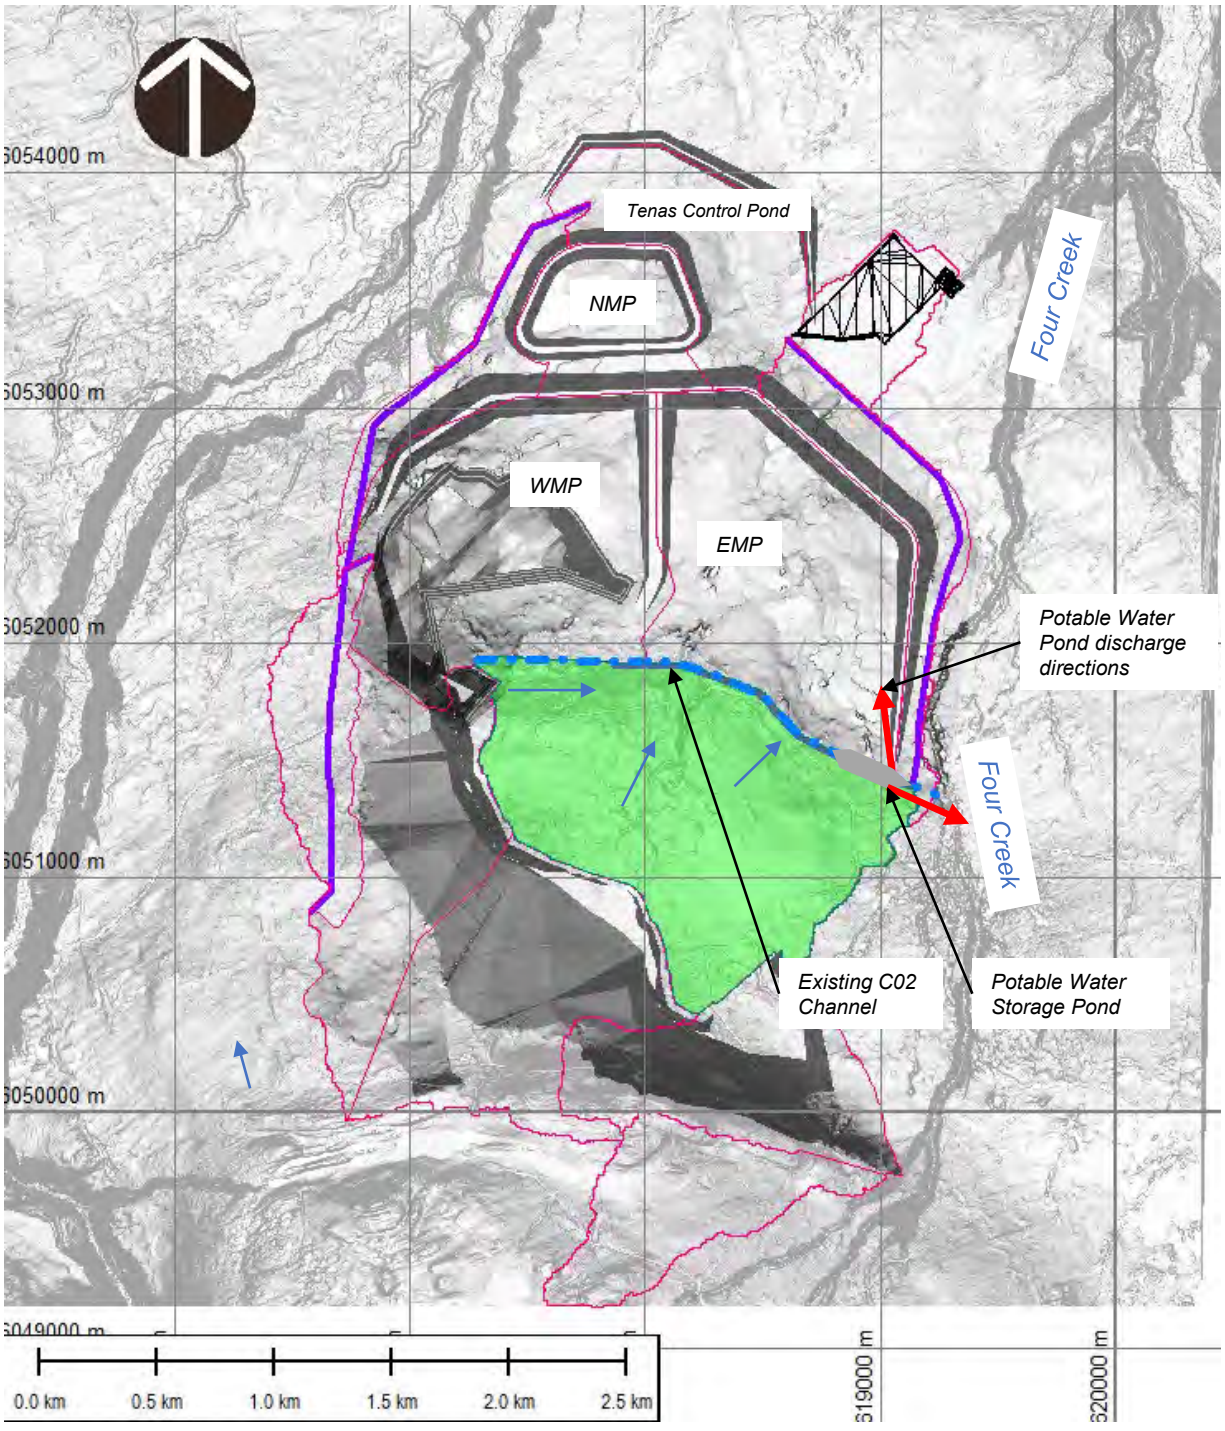

Figure 2-1: Mitigation Control 1 With Adjusted Discharge from Channel C02

2.2 Mitigation Controls 2, and 3: Modify Liner Design of the Management and Control Ponds

This control considers two liner modification options. Both options involve construction of a liner system in the management ponds and the Tenas Control Pond with a modified design that would improve on the performance assumed for the Updated EAC Project Case (2024). The liner systems considered include:

Updated EAC Project Case (2024):

- Soil-bentonite liner (0.3m) for EMP, NMP, and WMP (excluding WMP End Wall rock);
- Bituminous geomembrane liner for the Tenas Control Pond.

Mitigation Control 2:

- Soil-bentonite liner (0.56m) for EMP, NMP, and WMP (excluding WMP End Wall rock);
- Bituminous geomembrane liner on top of soil-bentonite liner (0.15m) for the Tenas Control Pond.

Mitigation Control 3:

- Bituminous geomembrane liner on top of soil-bentonite liner (0.3m) for EMP;
- Soil-bentonite liner (0.56m) for NMP, and WMP (excluding WMP End Wall rock);
- Bituminous geomembrane liner on top of soil-bentonite liner (0.15m) for the Tenas Control Pond

Mitigation Control 2 includes a thicker bentonite amended liner, covering the management pond bottoms, and upstream dam slopes in the EMP, NMP, WMP, as well as the in-pit overburden portion of the WMP. Liner thicknesses are assumed to be 560 mm in management ponds compared to 300 mm in the EAC Project Case (August 2022). The Tenas Control Pond contains an added soil-bentonite liner of 150mm thickness compared to none in the EAC Project Case (August 2022).

Mitigation Control 3 is the same as Mitigation Control 2 for NMP, WMP, and TCP. The only change is an additional bituminous geomembrane liner on top of the soil-bentonite liner with a reduced thickness of 300mm for the East Management Pond.

Liner seepage modeling and the site groundwater model were used to estimate the seepage losses from the facilities and the associated flow rates and loading in the receiving environment. Table 2-1 presents the revised groundwater inflows and outflows from lined facilities with the modified liners in Mitigation Controls 2 and 3, with the default values incorporated in the Updated EAC Project Case (2024) (as the base case) in brackets for comparison.

It is debatable whether a composite liner is a technology or if construction of such a liner is a BMP. Either way, Mitigation Controls 2 and 3 were included for consideration in the BAT assessment.

Table 2-1: Revised Groundwater Inflows and Outflows [m^3/day] from Project Facilities with Modified Liners in Mitigation Controls 2 and 3

Phase	WMP Case 2/Case 3 (base case)	NMP Case 2/Case 3 (base case)	EMP Case 2/Case 3 (base case)	Tenas Control Pond Case 2/Case 3 (base case)
Groundwater inflow to Facilities

Source: Z:\01_SITES\Telkwa Coal\1CT027.003_2020 EA Water Management\500_Water_Balance\Inputs\Groundwater\Telkwa_Summary_2022_GW_model_results_20211103_sab.xlsx

The modified liners would reduce the seepage rate from the management and control ponds to the receiving environment, which reduces streamflow and concentrations of parameters influenced by the Project.

2.3 Mitigation Control 4: Increase of Process Water to CPP plant

The current EAC application has the CPP producing a dry (25% moisture) processed rock stream comprised of course and fine material that is then hauled and placed into the management ponds. The primary reason for this was to limit water use by the CPP. However, as the Project discharges water every year when in the Operation phase even during drought conditions there is an opportunity to go to a conventional wet slurry system for the fine processed rock stream. This will double the amount of water required by the CPP (360,000 m^3/year vs 180,000 m^3/year) with the benefit of permanently tying up this water into the coarse and fine processed rock products within the management ponds. Water is taken out of the Pit Sump, and out of Tenas Control Pond if there is not enough water in the Pit Sump for process make up water which would improve water quality discharged by the Project. The process water intake acts as a sink of water and load in the model and is modelled to reduce load overall for the Project.

2.4 Mitigation Control 5: Incorporation of Blasthole Liners

Blasting residuals (undetonated ammonium nitrate fuel oil (ANFO) explosives) is one of the two sources of nitrogen (nitrate, nitrite, and ammonium) in water on site and is accounted for in the source terms where rock is placed in different facilities (backfill pit, management ponds, dams, and buttresses). Exchangeable ammonia present in sedimentary rocks is another potential source of nitrogen for this Project.

Loadings of residual nitrogen species that leach from the rock can be decreased if blasthole liners are used as holes are loaded with explosives as they reduce the potential for dissolution of ANFO prior to blasting. In this mitigation control, the model assumes a total ANFO loss of 1.25% instead of 2% which is based on 75% effectiveness of the blasthole liners and that 50% of available nitrogen comes from blasting while the remaining 50% being sourced from exchangeable ammonia present in sedimentary rocks.

2.5 Mitigation Control 6: Active/Passive Flocculation in Tenas Control Pond

Sediment/Control ponds for the Project were designed based on the monthly mean maximum level of Total Suspended Solids (TSS) release of 35 mg/L to remain below the proposed federal Coal Mine Effluent Regulations for TSS. This mitigation control is modelled to reduce total parameter concentrations but will not affect dissolved parameter concentrations. This is one of the available additional mitigation controls reviewed during the BAT analysis (Appendix H).

In Mitigation Control 6, the model assumes that we are adding flocculants to the sediment pond (Tenas Control Pond), therefore allowing us to recalculate the total parameter concentrations based on a new threshold, which was estimated to be 5 mg/L on average.

2.6 Mitigation Control 7: In-situ Active Gravel-bed reactors in the management ponds

Mitigation Control 7 assumes that In-situ Active gravel-bed reactors (GBR) is an active water treatment measure that could be implemented within the management ponds to remove nitrate, nitrite, selenium and some metals. This is one of the mitigation controls considered in the BAT assessment (Appendix H).

A GBR is usually defined as an engineered semi-passive treatment system that contains a fixed-film bioreactor containing a uniform media such as gravel. These reactors usually use a simple organic substrate such as manure, hay, or straw to increase and sustain microbial growth and promote the reduction of parameters such as nitrate, and selenium. However, the GBRs envisioned for the Tenas Project would be actively operated by dosing degradable organic carbon such as methanol to improve the control of reducing conditions within the GBR. As such, the GBRs are considered an active water treatment technology.

PAG and Non-PAG rock is modelled to be the primary source of selenium, nitrogen species (nitrate, nitrite, and ammonia), and metals such as nickel. Non-PAG rock will be used for construction of management pond dams and buttresses as well as the Tenas Control Pond dam, while the remainder of Non-PAG rock is backfilled into the south end the open pit. PAG rock is contained in the management ponds, kept fully submerged after it is placed, and is only a source of selenium and nitrogen species with the initial flush of this rock while it is being submerged.

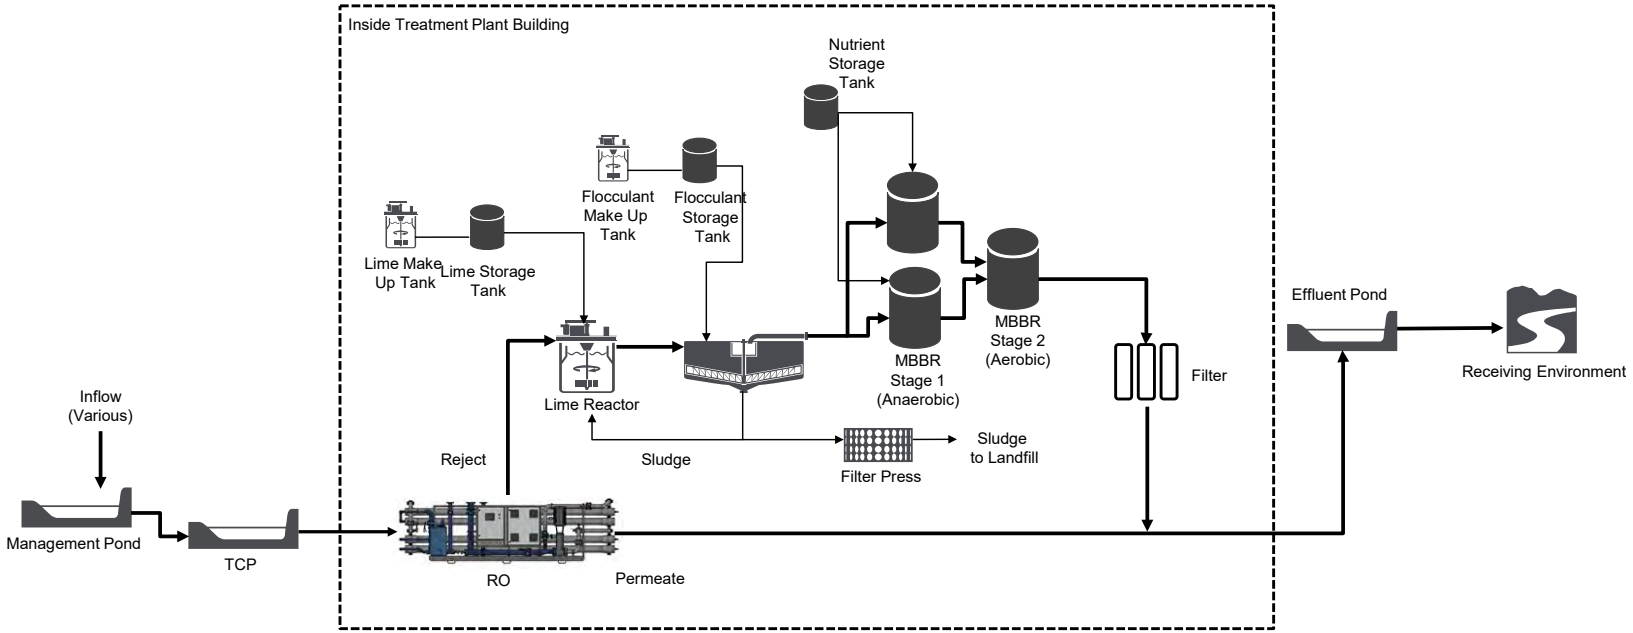
In the early Operation phase, the seepage from management pond and Tenas Control Pond dams and associated buttresses are the dominant sources of selenium, nitrite, sulphate, and nitrate loading in Project water. Once backfilling of the open pit begins, the open pit dewatering stream becomes additional source of selenium, nitrite, sulphate, and nitrate. Therefore, in addition to water contained in the management ponds, sources of mine water to be treated for the Project include:

- Seepage from the dams and buttresses surrounding Tenas Control Pond and the management ponds.
- Drainage from the open pit backfill reporting to the Pit sump, and
- Water reporting to the CPP Sedimentation Pond.

These water sources will be first be routed to the CPP Sedimentation Pond and then pumped to the active management pond for treatment. Loadings from the rock placed in the management ponds (primarily PAG with some non-PAG rock) as well as any water reporting through runoffs to the ponds, will be treated in-situ as well.

During freshet, it is assumed that runoff from the surrounding catchments bypasses treatment due to the short residence time in the system. Outside of freshet, any water pumped out of the In-situ Active GBR treatment system is assumed to be treated. Similarly, most of the water contained in the management ponds would be maintained in a state of mild reducing conditions, which will attenuate selenium, nitrate, and some metals species. Therefore, seepage from the management ponds that reports to the groundwater system is assumed to have a composition like treated GBR effluent.

NMP becomes active shortly after the Construction Phase and stops treating once the EMP becomes active, after two years of PAG placement in EMP. WMP also becomes active once it has had two years of PAG placement and remains active indefinitely, while EMP becomes inactive once WMP comes online.



Constituents targeted by the active in-situ GBRs is assumed to be reduced to the following concentrations in the treated effluent:

- Nitrate: 1 mg/L
- Nitrite: 0.02 mg/L
- Selenium: 0.003 mg/L
- Other parameters that get removed but not specifically targeted: Aluminum (0.1 mg/L), Nickel (0.01 mg/L), and Iron (0.3 mg/L).

2.7 Mitigation Control 8: Active Tank-Based Treatment of Tenas Control Pond Effluent

Mitigation Control 8 assumes that an active water treatment plant will treat water surplus from Tenas Control Pond, before it is discharged to the receiving environment. Similarly to Mitigation Control 7, active treatment options were reviewed in the BAT assessment (Appendix H). The active treatment processes are assumed to operate indefinitely. To treat the Parameters of Concern based on the assumption that the treatment chain is as follows and as shown in Figure 2-2:

1. Reverse Osmosis (RO)
2. Moving Bed Biofilm Reactor (MBBR)
3. Lime High-Density Sludge plant.

Source:
https://srk.sharepoint.com/sites/NACAPR002055/Deliverables/Board%20Meeting%20Presentation%20Oct%202024/20241216%20Tenas%20BAT%20Assessment%20CAPR002055%20SRJ_CCM.pptx?web=1

Figure 2-2: Example of Flowsheet for Active Water Treatment with RO, Anaerobic Bioreactor, and Lime Treatment

Based on this conceptual active water treatment design chain, the water treatment plant would achieve the following treated effluent concentrations:

- Nitrate: 0.5mg/L
- Nitrite: 0.01mg/L
- Sulfate: 200mg/L
- Selenium: 0.001mg/L
- Aluminum: 0.05mg/L
- Cobalt: 0.003mg/L
- Copper: 0.0001mg/L
- Iron: 0.05mg/L
- Nickel: 0.005mg/L

The treatment rate is assumed to match the current surface discharge in the Updated EAC Project Case (2024) [10,000 to 12,000 m^3/d], which will be discharged to Goathorn Creek upstream of monitoring station WQSEA1 between May and October. The treatment rate was selected to ensure that there is no overflow from TCP during the Project's Operation and Post-Closure Phases to prevent the release of untreated effluent to the receiving environment.

2.8 Summary of Mitigation Control Scenarios

Mitigation Controls 1 through 8 described above were evaluated using the water and load balance model developed for the Project and compared against the Updated EAC Project Case (2024) to evaluate effects of the mitigation controls on downstream water quality and flow. The model was run using average hydrological conditions as well as with typical modelled source terms. The scenarios modelled are summarized by Table 2-2 along with comments on the modelled changes to streams and Project discharge.

Table 2-2: Summary of Mitigation Control Scenarios and Modelled Changes to Streams and Project Surface Water Discharge

ID	Description	Modelled Beneficial Changes	Modelled Adverse Changes
MC1	Improve the robustness of the water covers in the management ponds and reduce loadings from waste rock by increasing the site water inventory during freshet	- Improve winter month concentrations in Four and Tenas Creeks - Improves surface water discharge water quality	- Reduces streamflow in Four Creek during freshet
MC2	Modify MP and TCP liners and reduce seepage to streams	- Improves winter month concentrations in Four and Tenas Creeks	- Reduces winter baseflows in Tenas and Four Creeks - Increased surface water discharge flows and loads from TCP to Goathorn Creek
MC3	Modify MP and TCP liners and reduce seepage to streams	- Improves winter month concentrations in Four and Tenas Creeks	- Reduces winter baseflows in Tenas and Four Creeks - Increased surface water discharge flows and loads from TCP to Goathorn Creek
MC4	Increase of process water intake to CPP plant	- Reduced surface water discharged load to Goathorn Creek	- Reduces year-round streamflow in Goathorn Creek
MC5	Addition of blasthole liners	- Improved nitrogen (nitrate, nitrite, and ammonium) concentrations in groundwater seepage and surface water discharge pathways	- none
MC6	Active/Passive flocculation in TCP	- Lower total metal concentrations in surface water discharge to Goathorn Creek	- none
MC7	In-situ Active GBR in MPs	- Improves surface water discharge water quality for surface water and groundwater	- none
MC8	Active water treatment post TCP	- Improves surface water discharge water quality in Goathorn Creek	- none

3 Results

The following sections present the water and load balance results for each mitigation control along with the Updated EAC Project Case (2024) to evaluate the potential effects of each mitigation control on water quality and flow of effluent and the receiving environment. The results assume average hydrologic conditions and typical modelled geochemical source terms. Alternative assessment cases, such as low flows or high source terms will be presented in the updated Water and Load Model Report (SRK 2025).

WQGs that were used to evaluate water quality model results were selected based on the lowest value of BC Approved Water Quality Guidelines (BC ENV 2024a) or BC Working Water Quality Guidelines for freshwater aquatic life (BC ENV 2024b). For guidelines that depend on toxicity-modifying factors, medium background values from the baseline datasets within each creek were used.

A map of prediction nodes incorporated in the water and load balance model is presented in Figure 3-1. Details concerning the selection of prediction nodes are presented in SRK 2022 with the addition of WQSEA1 requested by regulatory agencies. Results for stream water quality are presented in Section 3.2 and Appendix E, following the description of the results for the Updated EAC Project Case (2024).

Streamflow results are also presented where a mitigation control would influence streamflow. Results consider the maximum monthly change in streamflow throughout the modelled period relative to baseline conditions (without effects of Project).

Discharge water quality results consider the end-of-pipe concentrations from the main site discharge point, which is the Tenas Control Pond (TCP) in operations and the North Management Pond (NMP) in Post-closure, as well as the groundwater seepage from the TCP and the three management ponds.

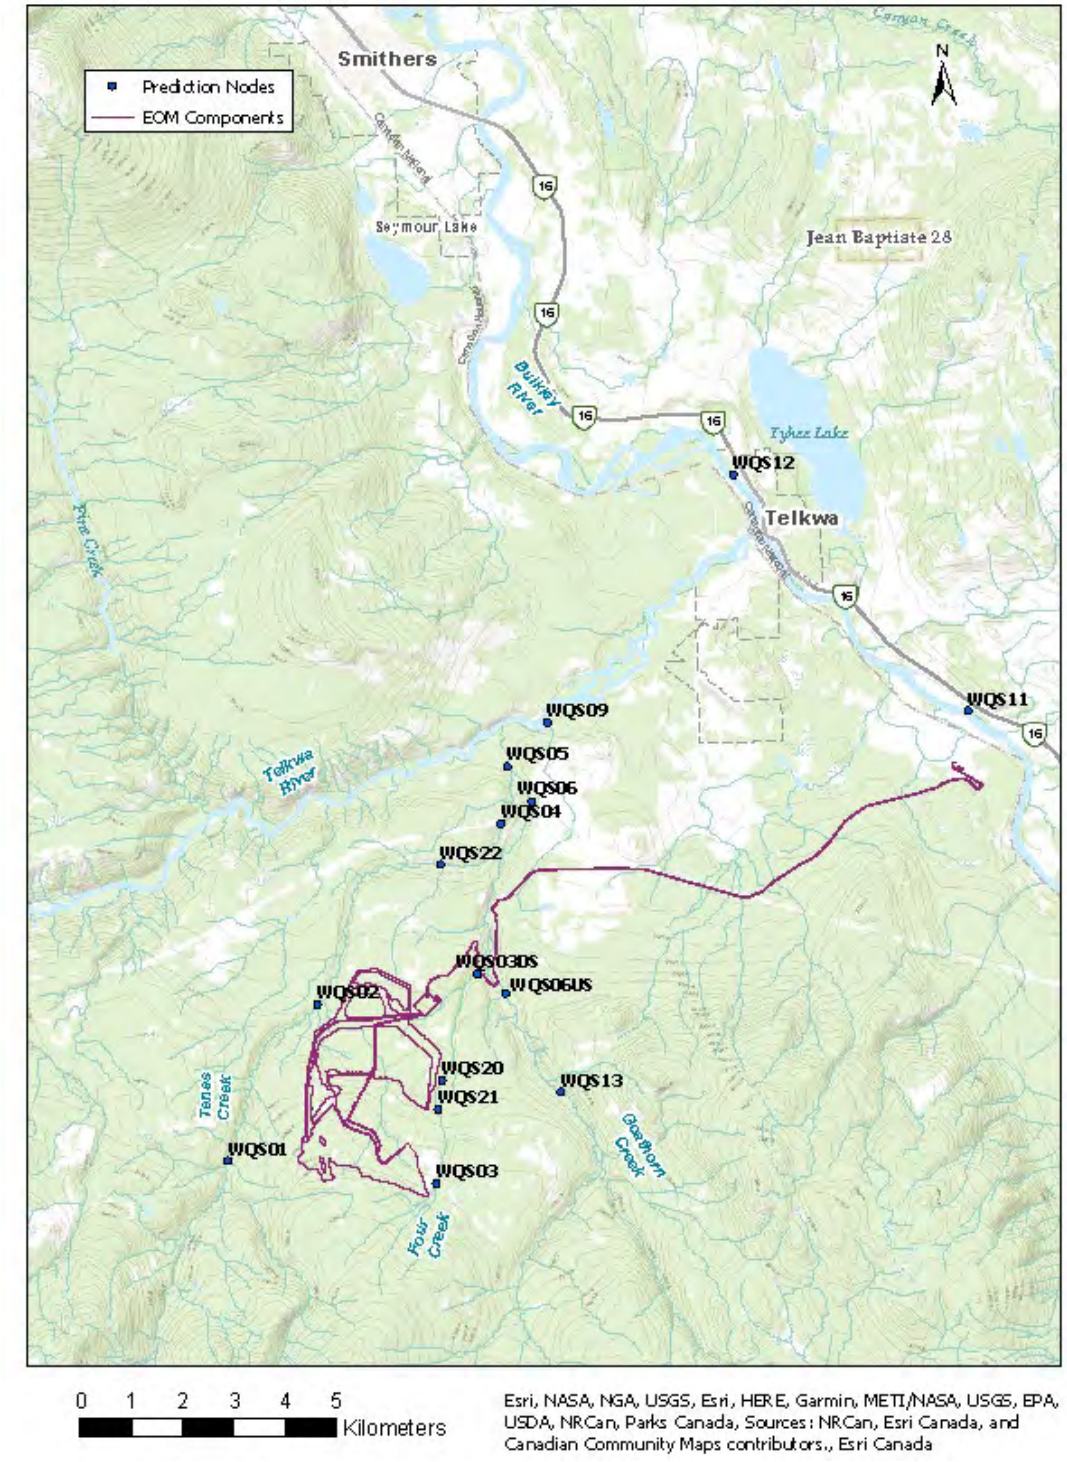


Figure 3-1: Map of Prediction Nodes in the Receiving Environment for the Tenas Project. Water and Load Balance Results are Produced for all Prediction Nodes that Have Water Quantity and Quality

3.1 Updated EAC Project Case (2024)

This section summarizes any modelled exceedances of WQGs in the environment for the Updated EAC Project Case (2024), as well as parameters of concern (POCs). POCs are identified as part of the BAT assessment process (Appendix H) and are the parameters that must be removed or reduced by candidate BATs. The Updated EAC Project Case (2024) is also referred to as the base case in this report.

3.1.1 Receiving Environment Results

The Updated EAC Project Case (2024) shows only one modelled WQG exceedance in the receiving environment in the three downstream creeks closest to the Project (Tenas, Four, and Goathorn Creeks) where the Project discharges directly either as surface water or groundwater. The modelled exceedance was for dissolved copper in Goathorn Creek with a maximum monthly average model result of 0.0021mg/L, which is greater than the calculated BC WQG of 0.0012mg/L for the Creek. However, background concentrations of dissolved copper are typically at similar levels that also exceed the WQG.

Tables summarizing modelled maximum monthly average parameter concentrations for each Creek is included in Appendix E.

3.1.2 Parameters of Concern (POC)

Table 3-1 summarizes POCs identified for the surface discharge (end-of-pipe) to the receiving environment or in pond seepage that reports to groundwater. POCs are defined as parameters in untreated effluent with concentrations greater than 80% of the BC WQGs (freshwater - aquatic life) or higher maximum monthly average model results. The maximum monthly average modelled results for the POCs can be found in Appendix E. Eleven POCs were identified based on the 80% of the BC WQG criteria and baseline conditions across the three Creeks (Goathorn, Tenas and Four Creek).

Table 3-1: Parameters of Concern in the Different Surface Water Discharges and Groundwater Seepages to the Receiving Environment

	Surface Water Discharges			Groundwater Seepages (Post-Closure)				Background / Baseline

3.2 Stream Water Quality

Since there are no modelled water quality exceedances in the receiving environment for the Updated EAC Project Case (2024) (except for dissolved copper in Goathorn Creek due to background concentrations), the relative change between the Updated EAC Project Case (2024) and the eight mitigation controls will be presented for the POCs identified in Section 3.1.2. These relative changes are presented for the Creeks affected the most by surface flow discharges or groundwater seepages due to their lower flows and proximity to the Project – Goathorn, Four, and Tenas Creeks. No notable effects on water quality are modelled downstream of the prediction nodes in these creeks and therefore will not be discussed further in this document (e.g., Telkwa, and Bulkley Rivers).

Results are summarized in Table 3-2 to Table 3-12 and figures showing modelled time series results for the three creeks are attached in Appendix F. The results are discussed in relation to the water quality guidelines in the respective streams and compared in terms of reduction in maximum monthly average modelled concentrations over the Updated EAC Project Case (2024).

General observations:

- As mentioned in Section 3.1.1, the only water quality exceedance is in Goathorn Creek for dissolved copper, and no mitigation control lowers the maximum monthly average modelled result for this POC.
- No additional exceedances are modelled in Goathorn, Four, or Tenas Creeks due to unintended effects of the mitigation controls considered.
- The mitigation controls with the most effect on groundwater seepages, and therefore Tenas and Four Creeks are Mitigation Controls 2 and 3 that include modified liners in the management ponds and the TCP, which reduce the seepage reaching Four and Tenas Creeks. The reduction in seepage and subsequent load decreases the concentrations of the POCs by 85% (Mitigation Control 3) of the concentration found in the Updated EAC Project Case (2024) for nitrate in Four Creek.
- The mitigation controls with the most effect on the surface water discharge are Mitigation Controls 7 and 8 (active treatment of Project water), which reduce the concentrations of most of the POCs in Goathorn Creek by 82% of the concentration found in Updated EAC Project Case (2024) for total selenium.
- Mitigation Control 1 (increase water inventory in management ponds) reduces concentrations of only some POCs (e.g. nitrate, sulphate, selenium total, nitrite, dissolved nickel) for Tenas and Four Creeks, but does not reduce the POC concentrations that are elevated in background waters such as total iron and dissolved copper since it is background water that is being added to the management ponds for this mitigation control.
- As expected, Mitigation Controls 5 and 6 reduces concentrations of nitrogen species or total metals, respectively.
- Mitigation Control 4 (increase of process water to CPP plant) had very minimal beneficial effect on POC concentrations and in some cases slightly worsened the conditions in the Creeks (Tenas and Four). This is because the seepage from the open pit backfill contains little load at the beginning of

mining (until 2029) and provides some dilution in the active management ponds, which in turn start to seep to the receiving environment. If less dilution is provided in the management ponds, the load seeping through the groundwater system to the receiving environment will therefore be higher, at the same seepage rate.

3.3 Streamflow

Mitigation Controls 1, 2, 3, 4, 7, and 8 have the potential to change the streamflow in the receiving environment.

- Mitigation Control 1 could reduce the natural runoff discharging into Four Creek, which would change streamflow at prediction nodes WQS21 (directly downstream of the C02 Channel discharge) through WQS03DS (the furthest downstream prediction node in Four Creek).
- Mitigation Control 2 and 3 could reduce flows discharging through the liners of the management ponds, which would change the baseflow rates into Four Creek at the downstream prediction node (WQS03DS) and Tenas Creek at the downstream prediction node (WQS04).
- Mitigation Control 4 could reduce the amount of surface discharge from the Project as more water is sent to the CPP plant overall in Goathorn Creek.
- Mitigation Control 7 changes the way the flows are routed within the Project, and therefore could affect timing and magnitude of surface discharge to Goathorn Creek.
- Mitigation Control 8 prevents any overflow from the TCP and therefore also changes timing and magnitude of surface discharge to Goathorn Creek, despite mimicking as closely as possible the discharge plan from the TCP in the Updated EAC Project Case (2024).

Change in streamflow is calculated based on the relative change between monthly average flow with the Project and its associated mitigation controls and the base case without the Project. The comparison presented below focuses on the maximum monthly reduction in streamflow for each month during the Operation phase of the Project. These effects are shown for three Creeks: Four, Tenas, and Goathorn Creek.

During the Decommissioning and Reclamation phase, the Channel C02 in Mitigation Control 1 would discharge to Four Creek year-round. For this reason, no change is modelled relative to the Updated EAC Project Case (2024) during the Post-closure period. The thicker liners in Mitigation Control 2 and 3 would result in a similar reduction to winter baseflows in Post-closure as in Operation phases in both streams.

Table 3-13 presents the maximum monthly reduction in streamflow at the upstream and downstream prediction nodes in Tenas Creek (WQS04, WQS02). Mitigation Controls 2 and 3 are the only cases modelled to influence flows in Tenas Creek.

Table 3-14 presents the maximum monthly reduction in streamflow results in Four Creek for the prediction node directly downstream of channel C02 (WQS21) and the furthest downstream prediction node (WQS03DS).

Table 3-15 presents the maximum monthly reduction in streamflow results in Goathorn Creek for the prediction node the most upstream in Goathorn Creek (WQS06US) and directly downstream of the surface discharge from the Project (WQSEA1).

Tenas Creek flows could be reduced up to 11.6% relative to baseline conditions during operations, which is about 4% more than under the Updated EAC Project Case (2024) (without additional mitigation controls). The effect is most prominent for the downstream prediction node WQS04.

Four Creek winter flows could be reduced by up to 37.8% in the Operation phase, which is about 3% more than under the Updated EAC Project Case (2024) for the upstream prediction node WQS21, and up to 40% for the downstream prediction node WQS03_DS in August, which is 20% more than under the Updated EAC Project Case (2024). Since Mitigation Control 1 only changes the C02 Channel discharge around freshet, only this period is affected in the Operation Phase, and shows minimal reduction in freshet streamflow. The change to the management pond liners results in minimal changes in streamflow during the open-water season (April through October) for the upstream prediction nodes but reflect significant changes in the downstream prediction nodes.

Goathorn Creek maximum monthly reduction shows very minimal changes for any mitigation control. The biggest reduction in flow compared to Updated EAC Project Case (2024) is for Mitigation Control 1 in March for the downstream prediction node WQSEA1. The flow is reduced by up to 10% in the Operation Phase, which is about 3% reduction compared to the Updated EAC Project Case (2024).

3.4 End of Pipe Surface Water Discharge and Groundwater Seepage Water Quality

The primary surface discharge location is from the Tenas Control Pond during the Operation phase, and the North Management Pond during the Post-closure phase (if the Tenas Control Pond is decommissioned). In Mitigation Control 8 (active treatment post-TCP) the Tenas Control Pond would not be decommissioned as it is required for the operation of an active water treatment plant and therefore remains the surface discharge location to Goathorn Creek in the Post-closure phase. As highlighted in section 3.2.1, other discharges from the Project occur through groundwater seepages from the main facilities (TCP and the management ponds), and the modelled results for parameter concentrations for groundwater seepages are also presented here.

Model water quality results from each facility were compiled under each mitigation control listed above and screened against the BC water quality guidelines (freshwater protection of aquatic life). The model does not predict TSS concentration, but the Tenas Control Pond is designed to provide sufficient retention time for particles to settle within the pond to meet the maximum discharge target of 35 mg/L.

The following sections present the results for total selenium, nitrate, and dissolved nickel. The modelled results for the other POCs can be found in Appendix G.

3.4.1 Selenium

Maximum average monthly total selenium concentration results for each mitigation control and the Updated EAC Project Case (2024) are presented in Table 3-16 for the surface discharge from the Tenas Control Pond (Operation phase final discharge point) and the North Management Pond (Post-closure phase final discharge point). These results are also shown for groundwater seepages for all facilities (TCP and management ponds) in Table 3-17 and Figure 3-3 during operations and in closure, respectively.

Modelled concentrations that are greater than 80% of the BC WQG of 0.002 mg/L are highlighted in orange which result in total selenium being a POC in the context of the BAT. Model results show that Tenas Control Pond selenium end of pipe concentrations could only be lowered to less than the BC WQG with implementation of Mitigation Control 8 (active treatment) during operations and closure. For other mitigation controls the model results indicate that selenium concentrations would remain higher than the BC WQG in the Tenas Control Pond's end of pipe flows(Table 3-16, Figure 3-2 and Figure 3-3).

No mitigation control achieves total selenium concentration in the groundwater discharge below the BC WQG of 0.002 mg/L during operations (Table 3-17). Mitigation Control 7 (GBR in management ponds) is assumed to lower total selenium by 75% from the Updated EAC Project Case (2024) but remains as high as 0.006 mg/L in the TCP seepage. This is mainly because it was estimated that a GBR could achieve to a treated concentration of 0.003 mg/L, which is higher than the BC WQG. During closure, Mitigation Control 7 does achieve total selenium concentrations lower than the BC WQG in the seepage of most facilities beside west management pond which continues to receive water containing selenium from the reclaimed backfill (Table 3-18 and Figure 3-4).

Table 3-16: Selenium End of Pipe Surface Water Discharge Quality Results with Mitigation Controls

Figure 3-4: Total Selenium Water Quality Results for the West Management Pond During the Post-Closure Phase in Groundwater Seepage

3.4.2 Nitrate

Model results for maximum monthly average nitrate concentrations with each mitigation control and the Updated EAC Project Case (2024) are presented in Table 3-19 for the surface discharge from the Tenas Control Pond (Operation phase final discharge point) and the North Management Pond (Post-closure phase final discharge point). These results are also shown for groundwater seepages for all facilities (TCP and management ponds) in Table 3-20 and Table 3-21 during operations and in closure, respectively.

Nitrate concentrations that are modelled to be higher than 80% of the BC WQG of 3 mg/L are highlighted in orange which result in nitrate being a POC in the context of the BAT. Model results show that Tenas Control Pond nitrate concentrations could only be lowered to level less than the BCWQG with implementation of Mitigation Control 7 or 8 (active treatment) during operations. During closure, nitrate concentrations remain lower than the BC WQG in all cases including the Updated EAC Project Case (2024) because the source of nitrate has been eliminated with the end of mining (Table 3-19, Figure 3-5 and Figure 3-6).

In the groundwater seepage, only Mitigation Control 7 (In-situ GBR Active) lowers nitrate concentrations below the BC WQG of 3 mg/L during operations for the TCP and WMP (Table 3-20). Nitrate in the NMP groundwater seepage remains below the BC WQG throughout operations. Nitrate in EMP groundwater seepage is lowered through Mitigation Controls 5 and 7 (addition of blasthole liners and passive treatment) in operations.

During closure, nitrate in the groundwater seepage remains below the BC WQG for TCP, NMP and EMP in the Updated EAC Project Case (2024) and all other mitigation controls (Table 3-21). In WMP, the groundwater seepage is above the BC WQG at the beginning of closure beside Mitigation Controls 5, and 7 (blasthole liner and passive treatment) (Table 3-21 and Figure 3-4). WMP is the facility where the last of the PAG and Non-PAG rock will be placed, and therefore the nitrate load flushing from the rock placed in the pond tails off during Post-closure but eventually lowers to below BC WQG 10 years past Closure in the Updated EAC Project Case (2024) please see Figure 3-7.

Table 3-19: Nitrate (as Nitrogen) End of Pipe Surface Water Discharge Quality Results with Mitigation Controls

Figure 3-7: Nitrate Water Quality Results at West Management Pond During the Post-Closure Phase for Groundwater Seepage

3.4.3 Dissolved Nickel

Model results for maximum monthly average dissolved nickel concentration are listed in Table 3-19 for each mitigation control and the Updated EAC Project Case (2024) the Tenas Control Pond (Operation phase final discharge point) and the North Management Pond (Post-closure phase final discharge point). These results are also shown for groundwater seepages for all facilities (TCP and management ponds) in Table 3-23 and Table 3-24 during operations and in closure, respectively.

Results exceeding 80% of the BC water quality guideline for dissolved nickel, calculated based on the biotic ligand model[2] (BC ENV 2024) are highlighted in orange. Model results show that concentrations of dissolved nickel in the Tenas Control Pond are greater than the BC WQG even with Mitigation Controls during operations and hovers around the BC WQG calculated for Goathorn Creek (0.0022mg/L) in Post-Closure (Table 3-22, Figure 3-8 and Figure 3-9). The greatest modelled concentration reduction in TCP for dissolved nickel is noted for Mitigation Control 7 (In-situ Active GBR treatment), which is likely linked to the re-routing of mine water away from the TCP to the management ponds for in-situ treatment of nitrate and selenium in the In-situ Active GBRs in the management ponds, and not actual treatment of dissolved nickel (see Section 2.6). These results are expected as the treated effluent target for dissolved nickel (Mitigation Control 8) at 0.005 mg/L is higher than the BC WQG calculated value of 0.0022 mg/L for Goathorn Creek.

Similarly, for the groundwater seepage, all cases (including the Updated EAC Project Case (2024) and mitigation controls remain above the BC WQG for dissolved nickel during operations (Table 3-23). However, dissolved nickel is equal to or below the BC WQG for most cases (Updated EAC Project Case (2024) included) in the groundwater seepage for TCP, NMP and EMP. Dissolved nickel in WMP groundwater seepage during Post-Closure (Table 3-24) remains above the BC WQG calculated for Four Creek (at 0.0025 mg/L) in all cases, which is due to the continued input of impacted water containing nickel from the reclaimed backfill during the Post-Closure Phase. Dissolved nickel concentrations eventually decrease in the groundwater seepage for the Post-Closure phase approximately 30 years after closure for most cases, except Mitigation Controls 2, 3, and 7. In Mitigation Controls 2, and 3, it is because the liners reduce seepage to the environment and therefore keep a higher load in the management ponds. In Mitigation Control 7, the re-routing of water from the dams and buttresses for all facilities to the WMP result in a higher load of dissolved nickel compared to the Updated EAC Project Case (2024).

[2] Each facility discharges into a specific Creek for which the dissolved nickel guideline was calculated based on the median for historic measured water quality for hardness, Dissolved organic Carbon and temperature individual or each Creek. Surface discharge water is compared to Goathorn Creek nickel dissolved guideline, and for the groundwater seepage, it is compared to the most upstream point where the groundwater seepage connects with the creek. For NMP, WMP and TCP, it is compared to Tenas Creek, and for EMP it is compared to Four Creek.

3.5 Summary

This section summarizes the results of the water quality model assessment of the potential mitigation controls that were identified for the Tenas Project to help improve water quality in the receiving environment relative to conditions presented in Updated EAC Project Case (2024). As there are no modelled exceedances of BC WQG in the downstream receiving waters, the effectiveness of each mitigation control was evaluated in terms of improving the surface water discharge (end-of-pipe) and groundwater seepages from the Project, in Goathorn Creek, Tenas Creek and Four Creek, along with any associated changes to streamflow or Project surface water discharge and groundwater seepage.

In summary, the mitigation controls include:

- Improve the robustness of the water covers of the management ponds by adding freshet inflows from Channel C02.
- Modifying liners constructed for the management and control ponds to reduce seepage rates to the receiving environment.
- Increase of process water usage by the CPP by changing the deposition method for the CPP tailings.
- Use of blasthole liners to decrease nitrogen loads.
- Active/Passive flocculation with the Base Case to reduce total metals concentrations in surface discharge.
- Treating water collected in the open pit, as well as dams and buttresses seepage with the Base Case
  - through In-situ Active GBR treatment in the management ponds for both surface water discharge and groundwater seepage, or
  - through active water treatment post TCP (for surface water discharge treatment)

Table 3-25 summarizes changes to stream water quality and quantity.

Table 3-25: Summary of Mitigation Control Results

Mitigation Control ID	Positive	Negative
MC1: Improve Water Cover	- Reduces most POCs concentrations by a few percent for surface water discharge from the Tenas Control and North Management Ponds, as well as in groundwater seepages. - Reduces POCs in streams as well to varying degrees in Tenas and Four Creeks with no significant improvements in Goathorn Creek.	- Reduces streamflow in Four Creek during the open-water season months. - Does not improve POC concentrations for NMP as it is not targeted.

Mitigation Control ID	Positive	Negative
MC2: Modified Liners in Management and Control Ponds (Option 1)	- Reduces POCs concentrations in Tenas and Four Creeks.	- Changes flows for the streams, with main effect on Four Creek (>12.5% reduction of flows, and further reduction over the Updated EAC Project Case (2024)). - Worsens TCP surface water discharge for a few POCs. - Worsens POCs concentrations in groundwater seepage from TCP and WMP.
MC3: Modified Liners in Management and Control Ponds (Option 2)	- Greatest improvement for a single mitigation control in reducing concentrations of most POCs in Four Creek. - Reduction of POCs concentrations in Tenas Creek (less than in Four Creek).	- Changes for stream flows, primarily Four Creek (>12.5% reduction of flows, and further reduction over the Updated EAC Project Case (2024)) (more than MC2). - Worsens TCP surface water discharge for a few POCs (more than MC2). - Worsens POCs concentrations in groundwater seepage from TCP and WMP (more than MC2).
MC4: Increase of process water to CPP	- No notable improvements of discharge water or water quality in the streams.	- Increased water usage by the Project.
MC5: Blasthole liners	- Reduces nitrogen concentrations in the surface water discharge and the environment between 30 to 40%.	- none
MC6: Active/Passive Flocculation in TCP	- Reduces total metals concentrations in the surface water discharge of TCP (Operations).	- No effect on seepage water quality - No effect on dissolved POC concentrations
MC7: In-situ Active GBR in MPs	- Greatest reduction in selenium, nitrite, and nitrate concentrations in Tenas Creek. - Some improvements in Four Creek water quality for selenium, nitrate, and nitrite. - Reduce maximum concentration of nitrate, selenium, and nitrite at groundwater discharge from both West Management and Tenas Control Ponds.	- none
MC8: Active treatment post TCP	- Greatest improvement in surface water discharge concentration of identified POCs, including nitrate, nitrite, total selenium, dissolved nickel. - Improvement in Goathorn Creek like MC7 for nitrite, nitrate, and selenium, but targets other POCs as well such as total molybdenum.	- Slightly worsens POCs concentrations in the groundwater seepage for EMP and TCP.

4 BMP Evaluation

As discussed in Section 1.4, the merits and feasibility of implementing the mitigation controls that were considered BMPs are evaluated here, while the mitigation controls that were candidate BATs were evaluated as part of the BAT assessment (Appendix H).

In summary, the BMP mitigation controls include:

- MC1: Improve the robustness of the water covers in the management ponds and reduce loadings from submerged rock by increasing the Project's water inventory during freshet.
- MC4: Increase of process water intake to CPP plant.
- MC5: Addition of blasthole liners.

Based on the results presented in Section 3, only MC5 (blasthole liners) was considered suitable and feasible as a mitigation control. Reducing loss and dissolution of ANFO is a true source control measure that would reduce loadings of ammonia, nitrite, and nitrate in Project water on site. Mitigation Control 5 (blasthole liners) was therefore recommended to be introduced into the Final EAC Project Case (2024) for subsequent information request responses.

The water and load balance model results showed that the option of improving the robustness of the water cover in the management ponds would cause an apparent reduction in POC concentrations but only because of dilution by additional non-contact water during freshet. Since this option in effect amounts to the addition of fresh dilution water to the management ponds, it was not considered to be consistent with best management practices and was therefore not pursued. Additionally, the model results indicated that increasing the process water intake by the CPP would have no to little effect on the quality of Project water and was also therefore not included either in the Final EAC Project Case (2024).

Evaluation of the water quality mitigation controls that are candidate BATs are discussed in the BAT assessment report (**Appendix H**). This report will recommend if further changes to the Updated EAC Project Case (2024) are required for the Final EAC Project Case (2024).

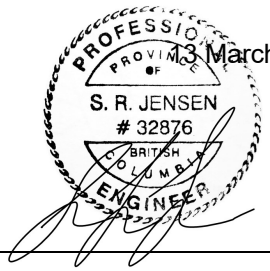
If any mitigation control or combination thereof is selected for implementation in the Tenas water management strategy, additional modeling is required to consider the effects on the mixing zone in Goathorn Creek, as well as varied hydrologic conditions (i.e., low flows) and source terms, like the scenarios considered and presented in SRK 2022. This will be provided in the Final Water and Load Balance Report (SRK 2025) for the Final EAC Project Case (2024).

5 Conclusion

This report summarizes the performance of water quality mitigation controls in terms of improvements (or changes) to effluent water quantity and quality as well as changes to water quality and streamflow in creeks and rivers downstream of the Project. Results were produced using the Water and Load balance model (SRK 2025) and compared against the Updated EA Case (2024) which was used as the Base Case.

The mitigation controls were divided in two categories – Best Management Practices (BMP) and Best Achievable Technologies (BAT). BMP mitigation controls included addition of blasthole liners, improvement of water cover robustness by adding freshet flows to management and control ponds, as well as increased use of process water by CPP from the Project Area. BAT measures included the use of modified liners in the management and control ponds, Active/Passive flocculation in the Tenas Control Pond, In-situ Active Gravel Bed Reactors in the management ponds, as well as active water treatment of end-of-pipe effluent.

Of the BMPs, blasthole liners were recommended to be adopted by the Final EA Case (2024) as other BMPs yielded unchanged to marginally improved water quality. The results for the BATs were presented in this report, but final recommendations as to whether to incorporate these mitigation controls by the Final EA Case (2024) were addressed in the BAT report (Appendix H).



Closure

1 Introduction

Telkwa Mining Ltd (TML) submitted an Environmental Assessment Certificate (EAC), application for the Tenas Project, located at the Telkwa Property, near the town of Telkwa, British Columbia in May of 2022. In support of the EA application, SRK Consulting (Canada) Inc. (SRK) developed geochemical source terms (SRK 2022a) that formed the basis for evaluating changes to water quality in downstream receptors. The source terms were based on humidity cell testing (HCT) results. In parallel to the geochemical characterization testing program that was used to support the EAC application, TML initiated a field barrel testing program in late 2019. Release rates from the barrel testing program were compared to the scaled results that formed the basis of the source terms that were developed to support the EAC application. The outcomes indicated that the scaled HCT release rates were underestimated for some constituents while overestimated for others. Updated source terms were developed using the barrel release rates to reflect release rates more accurately under field conditions.

This report describes the conceptual models, methods and assumptions used to derive the site water quality model source term inputs based on the field barrel testing results. The site wide water quality model development and results are described in SRK (2024a).

2 Project Background

2.1 Geological Setting

2.1.1 Bedrock Geology

The Tenas Project is located within the northeast/southwest trending Skeena Arch, which separates Jurassic-age sedimentary rocks of the Bowser Basin in the north from the Jurassic to Cretaceous-age sedimentary rocks of the Nechako Basin to the south. The coal-bearing sedimentary rock sequence of the Project is associated with the Lower Cretaceous age Skeena Group, and unconformably overlies the Jurassic-age Hazelton volcanic group, which will be below the proposed pit limit. A simplified stratigraphic column of the Project's deposit is presented in Figure 2-1.

Jurassic Hazelton Volcanic Group

The volcanic rocks include andesite, trachyte, and basalt with associated tuffs and breccias.

Lower Cretaceous Skeena Group

The Lower Cretaceous Skeena Group includes marine and continental sediments interbedded with coal seams, often correlated over long lateral distances. It is subdivided into four units (Units I through IV) and a unit of undivided sediments overlying the four units (Figure 2-1).

The economic coal seams in the Tenas area are located within Coal Zone 1 of Unit I and include two seams: C seam and 1 seam (upper and lower). Coal Zones 2 through 10, located in Unit III (Figure 2-1), are absent from the Tenas area. Units I through IV are summarized below.

- The Unit I consists of more than 100 m of fine to coarse-grained cross-bedded sandstone, conglomerate, siltstone, mudstone, and coal (coal zone 1). Overall, Unit I fines upward, from primarily conglomerate and sandstone to almost entirely carbonaceous mudstone, seatearth and coal (1A to 1G). The conglomerate and sandstone were deposited in braided channels and bars, and mudstone accumulated in floodplains. Thin coal seams formed in poorly drained, peat-forming backswamps, and seatearths formed under leaching conditions in less submerged areas. With denudation of the volcanic source area, braid plains were abandoned and extensive low-energy, peat-forming swamps were established, resulting in the formation of thick coal seams in the upper part of the Unit.
- The Unit II separates coal zone 1 and coal zone 2. It consists of up to 140 m of primarily monotonous silty mudstone, occasionally interbedded with beds of chert-rich, micaceous, bioturbated or cross-bedded sandstone. The sediments were deposited in a deltaic/shallow marine environment following a regional marine transgression. The mudstone accumulated in bays, and the sandstones in distributary channels and mouthbars. Locally, thin discontinuous peat beds formed in salt marshes.
- Unit III comprises about 90 m of chert-rich, micaceous sandstone, siltstone, and mudstone, and up to nine coal zones (coal zones 2 through 10). The sandstone and mudstone were deposited and biogenically reworked in a tidal flat environment; siltstone accumulated in a restricted, nearshore marine environment. Peat accumulated in freshwater coastal marshes which periodically prograded over tidal flats.

- Unit IV consists of approximately 150 m of a laterally extensive, bright green, chert-rich, chloritic sandstone or siltstone bed at the base, overlain by massive grey silty mudstone like that of Unit II. The basal sandstone is a transgressive lag deposit, and silty mudstone, the predominant lithofacies, was deposited in a quiet, nearshore, shallow marine environment.

Intrusions

Tertiary and Cretaceous-age porphyritic dykes and sills commonly intrude this sequence, the most notable of which includes a Tertiary granodiorite intrusion located on the north side of the Telkwa River. These intrusions are not present in the Tenas area.

Geological Structures

The sedimentary sequence in the Tenas area is folded into a syncline in which the gently (typically 10 to 20°) northeast-dipping western limb of the syncline subcrops on the western side of the pit area, while the moderately (40 to 45°) southwest-dipping eastern limb subcrops on the eastern side of the pit. Faulting is generally near-vertical, and can be subdivided into two main groups, one which strikes approximately northwest/southeast and the other which strikes approximately northeast/southwest. A few east/west striking faults have also been interpreted.

The Goathorn area is located within an outlier of the Lower Cretaceous Skeena Group. The structural geology is somewhat more complex than the Tenas area and is characterized by a complex series of sub-parallel north-south trending reverse faults, and to a lesser extent east-west, trending normal faults.

Northeast striking faults are related to emplacement of the Bulkley intrusions in the Late Cretaceous.

2.1.2 Surficial Geology

The surficial geology in the Project area consists primarily of two types of deposits, glacial clay- or silt-rich till, and sand and glaciofluvial sand and gravel outwash. At upper elevations and south of the proposed pit, the terrain is mapped as having bedrock outcrops to a limited extent or thin mantles of clay- and silt-rich tills deposits, between 3 m and 10 m thick. North of the proposed pit and towards Tenas Creek and Goathorn Creek, drillholes report thin mantles of clay- and silt-rich tills deposits, between 3 m and 10 m thick underlain by a thick sand and gravel outwash deposit that can exceed 100 m.

Other types of deposits are present locally. Patches of glaciolacustrine deposits are scattered throughout the morainal landscape in low ridges and in depressions; the sediments comprise bedded and laminated mud, and minor sand and gravel (Clague 1984). Recent fluvial deposits form the narrow floodplains of Goathorn Creek and Tenas Creek, which are 40 m to 80 m deep incised into the subdued morainal landscape, and the wide floodplains of the Telkwa and Bulkley Rivers. The fluvial deposits range from extremely coarse, poorly sorted gravel on steep alluvial fans to moderately to well-sorted sand and mud on low-gradient floodplains (Clague 1984).

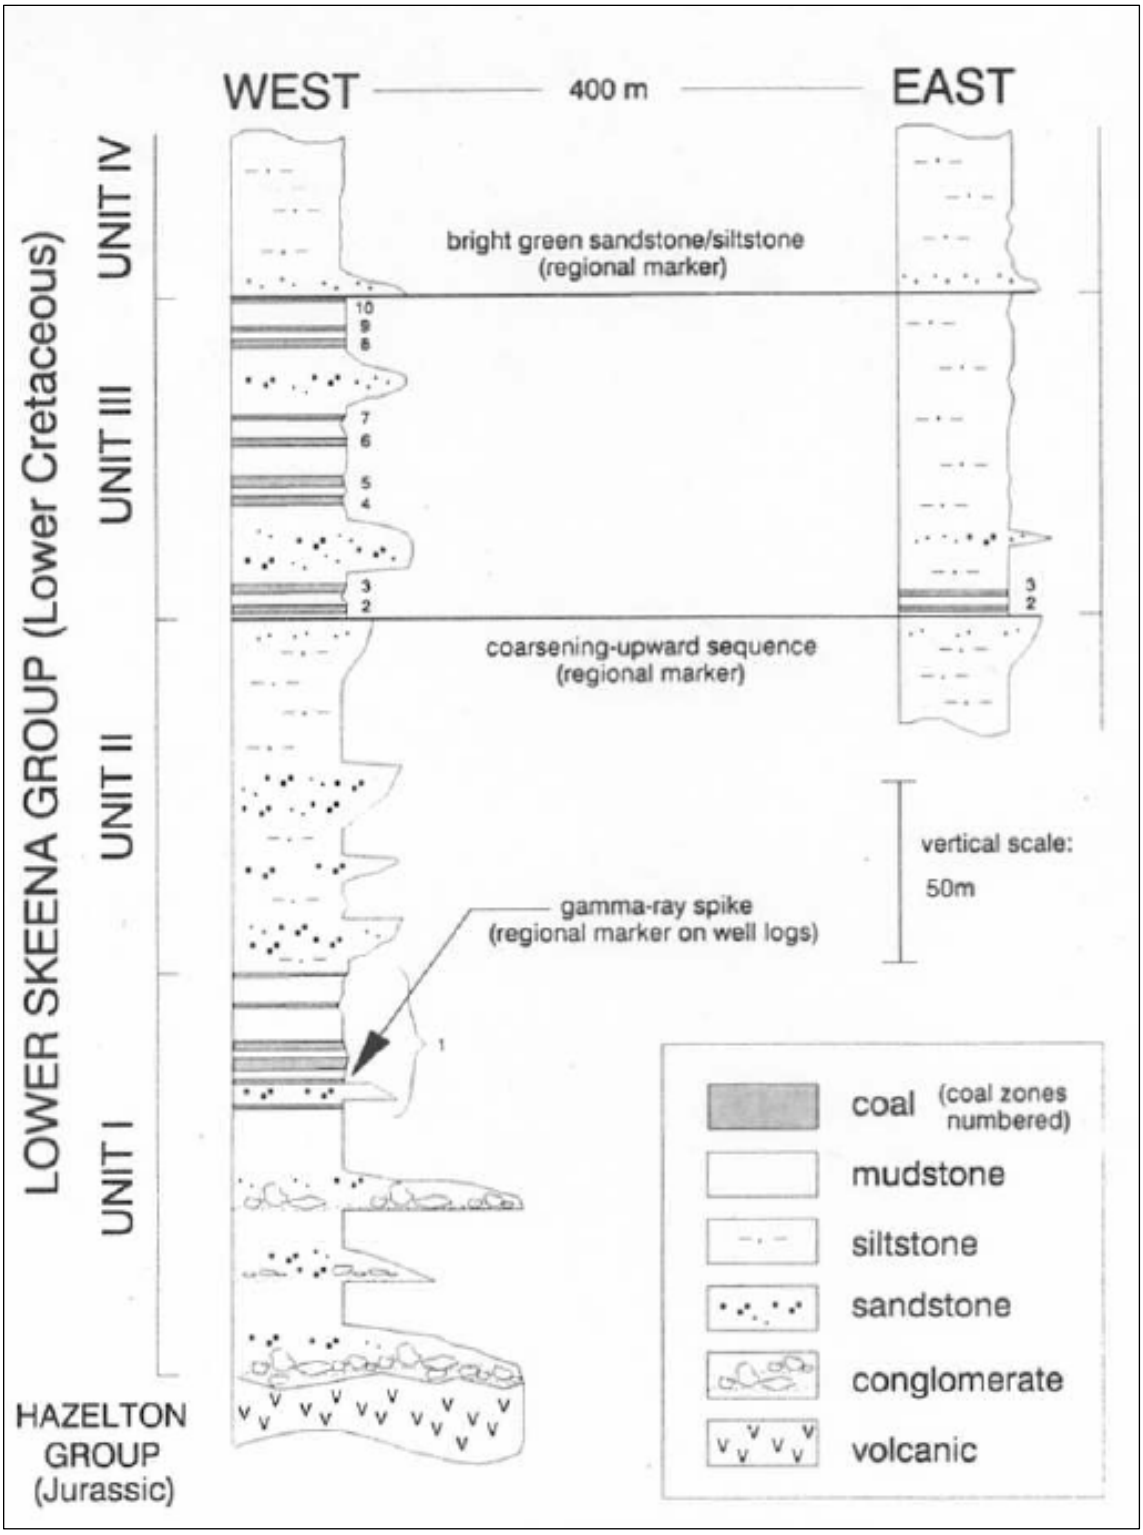

Figure 2-1. Stratigraphic Sequence of Lower Cretaceous Skeena Group Sediments.

2.1.3 Material Zone Designations

Geochemical properties are stratigraphically constrained in coal deposits versus lithologically constrained. For example, the deposition environment of the Tenas Deposit includes marine and deltaic sedimentary sequences and rocks formed in these two different environments will be compositionally different. The deposit was demarcated into stratigraphic zones of sedimentary sequences between the mineable coal seams. The stratigraphic zones were further divided into additional zones if they had different distinct geochemical properties (e.g., Zone 1 and Zone 1a) or grouped if geochemical properties were similar between zones identified between coal seams (e.g., Zone 2 and Zone 3). The stratigraphic zones and classification of PAG and non-PAG based on an NPR of 2.0 identified for the Project are presented in Figure 2-2.

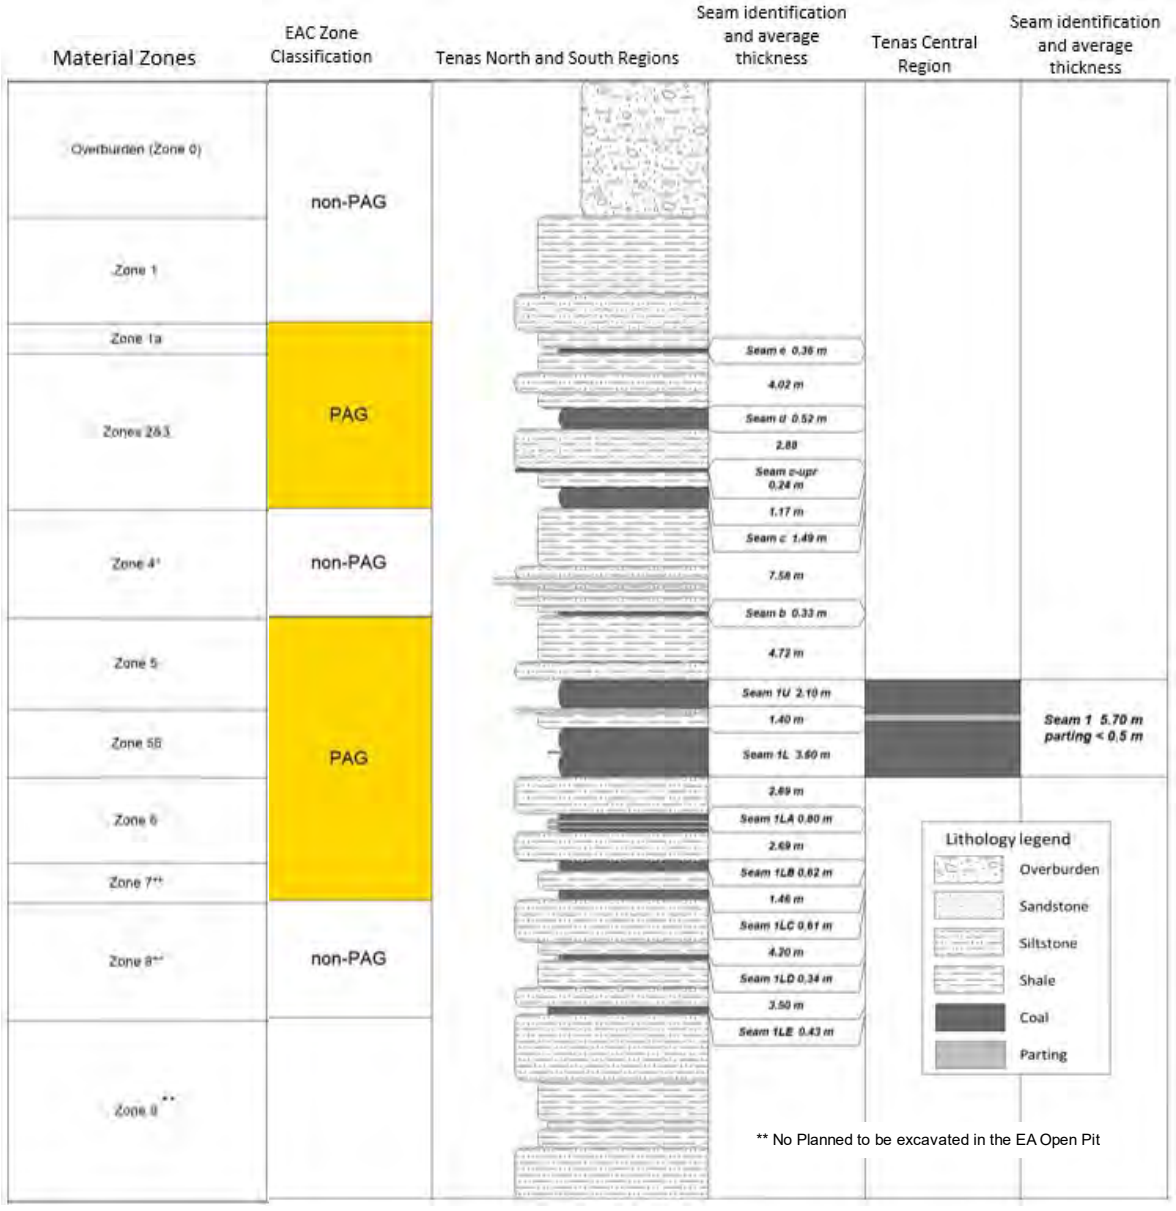

Figure 2-2. Tenas Deposit Stratigraphic Zones

2.2 Geochemical Characterization Study

Two geochemical studies have been completed to characterize the acid generating and metal leaching potential of the Tenas deposit:

- Norecol Dames and Moore (1999). Draft Report. Assessment of ARD Potential and Water Quality Predictions. Telkwa Coal Project.
- SRK (2022b). Telkwa Coal – Tenas Project Supplemental Geochemical Characterization.

The Norecol Dames and Moore (1999) study included the collection and analysis of over 700 samples. An additional 173 samples were collected as part of the supplemental geochemical characterization study (SRK 2022b). The supplemental samples were used to confirm the results of the 1999 study and correlate the test results to more up-to-date testing methods. For example, samples collected as part of the Norecol Dames and Moore (1999) study were analyzed for total sulfur only and neutralization potential was determined using the Sobek-NP (1978) method. Results from both studies were combined to form a robust geochemical characterization that is reported in SRK (2022b). The reader is referred to SRK (2022b) for additional detail on the geochemical characterization program including sample selection, collection, testing and results.

The outcomes of these studies indicated that a large volume of the rock to be mined from the Tenas deposit is potentially acid generating (PAG) and that acid generating potential is stratigraphically constrained in zones generally separated by coal seams. The geochemical properties of the deposit were therefore described based on mineable stratigraphical zones. The geochemical testing results indicate that all zones contain some PAG rock; however, there are units that are predominantly PAG versus non-PAG. Based on the site-specific neutralization potential ratio of 2.0 (NPR) and the average bulk geochemical properties, the following zones were characterized as PAG and non-PAG:

- Non-PAG: Zone 1, 4 and 8;
- PAG: Zones 1a 2/3, 5, 55, 6 and 7.

The geochemical characterization results also indicate that coarse and fine processed rock are PAG and overburden samples tested are non-PAG, including construction materials.

2.3 Summary of Mine Material Management Plan

Mining of the Tenas deposit will produce mine rock and processed rock materials. Previous geochemical testing (Norecol Dames & Moore 1999) indicates that the coarse and fine processed rock and a component of the mine rock will be PAG, and management will be required. Management of mine rock and coarse and fine processed rock are summarized in the following sections.

2.3.1 Management of PAG Rock

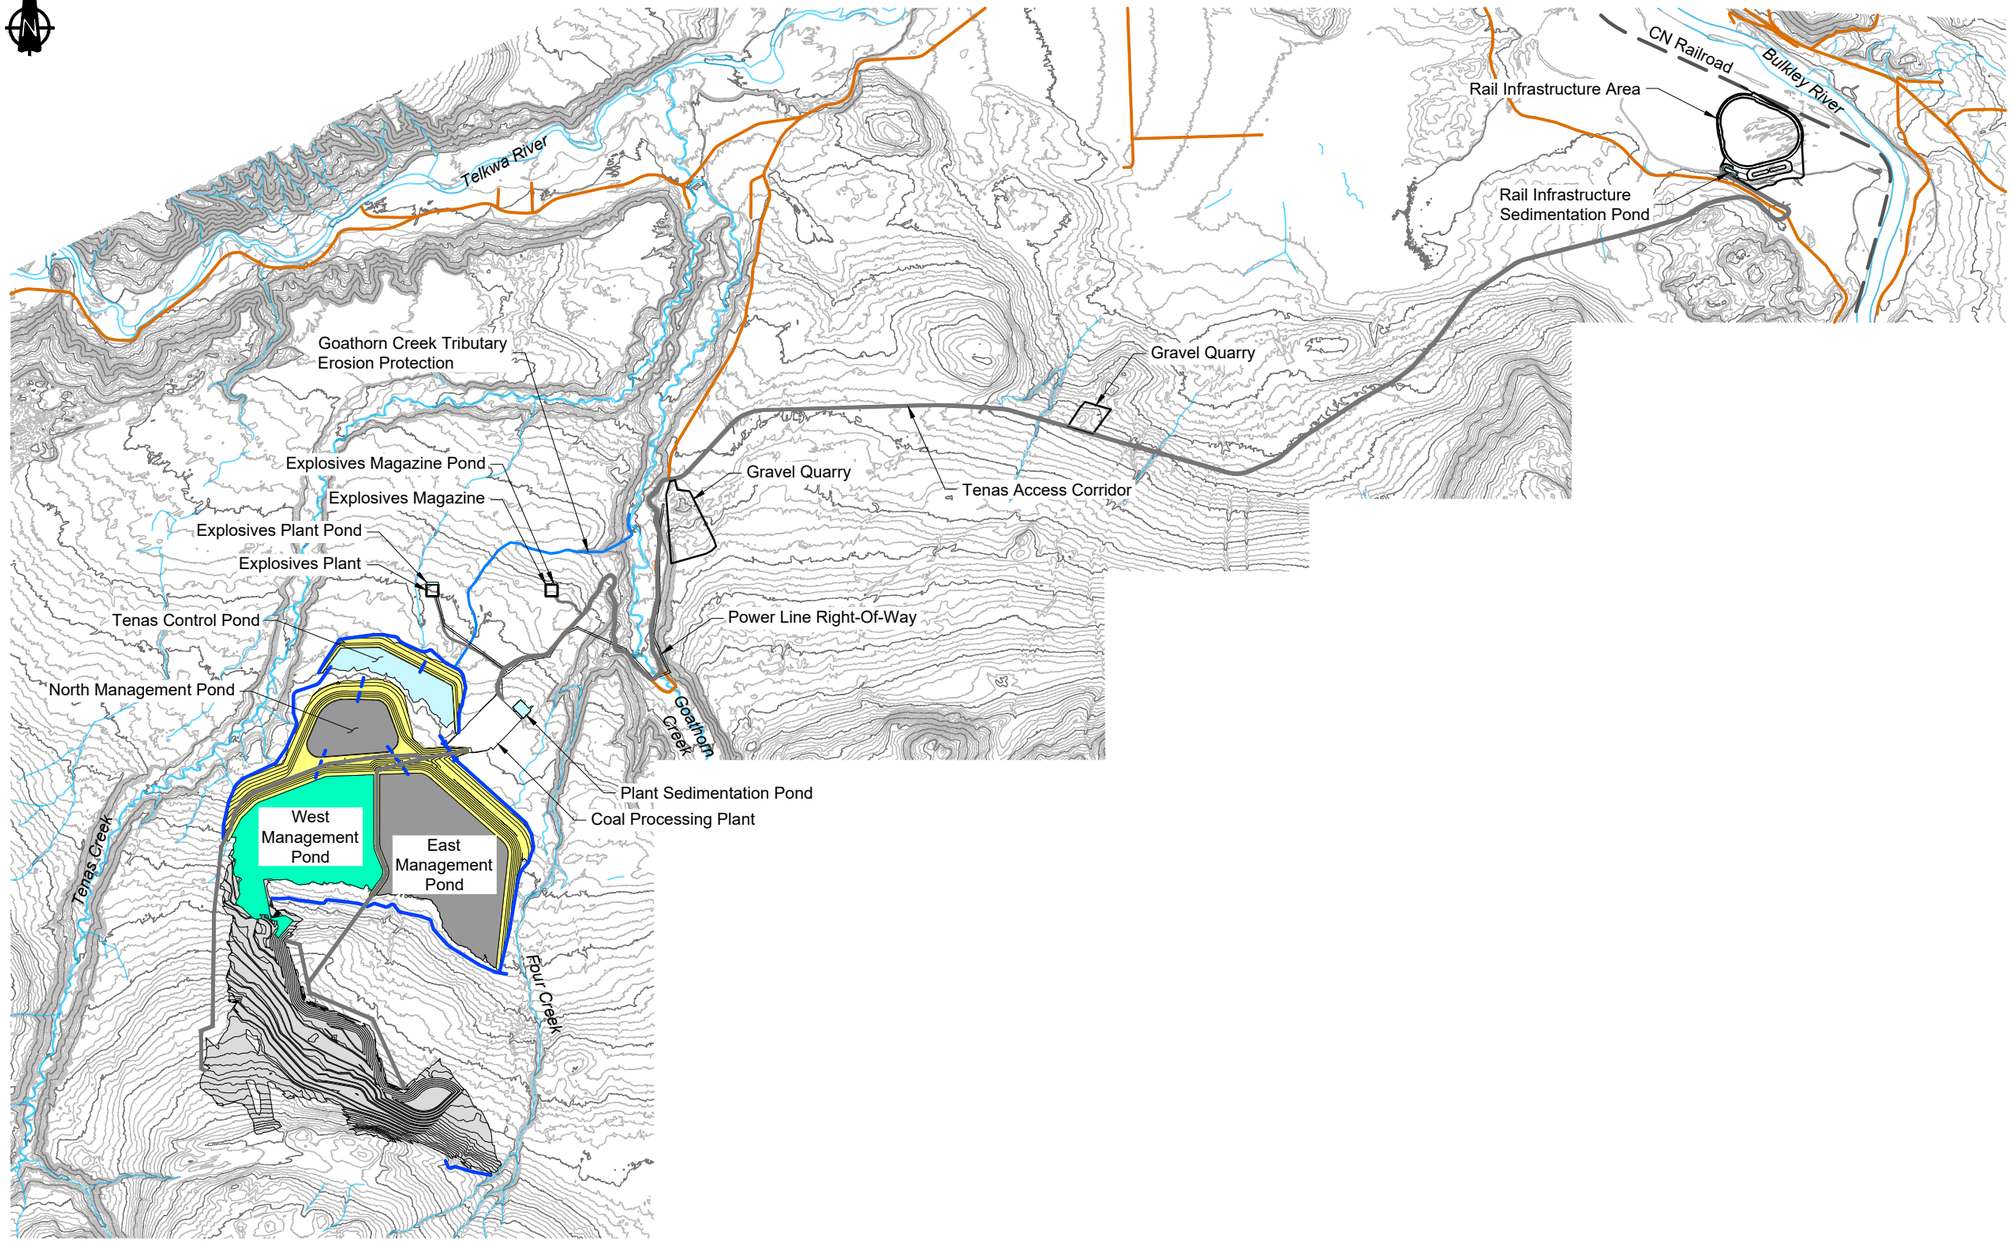
In advance of, and during mining, TML proposes to progressively construct Management Ponds with a combination of excavation and embankments with buttresses (Figure 2-3). The purpose of the management ponds is to store PAG and processed rock in saturated conditions preventing sulfide oxidation, limiting acidic drainage from occurring. Three management ponds will be constructed including the North, West and East Management Ponds. The North Management pond will be constructed first and is located north of the West Management Pond and is external to the open pit. The East Management is constructed next and is south of the NMP and external of the open pit. The last management pond, which is the West Management Pond which is constructed from a combination of excavation for the open pit for the North Phase and construction of an embankment external to the open pit.

PAG rock will first be placed in North Management Pond. PAG rock will be progressively placed in lifts and flooded as each lift is completed so that exposure of rock to atmospheric oxygen is minimized. TCL is proposing to place PAG rock including processed rock underwater before it becomes acid generating.

Once the storage capacity of the pond has been reached, storage will begin in the East Management pond and then the West Management Pond. The three management ponds will be independent of one another allowing different water levels and PAG material levels in each of the ponds as conditions require. The Management Ponds will be maintained with at least a two-metre water cover once PAG material disposition has been completed.

2.3.2 Management of non-PAG Rock and Overburden

Non-PAG rock will be used to progressively backfill the open pit during operations and for constructing portions of the embankments and buttresses for the Management Ponds and Control Ponds. Some non-PAG rock will also be used to cap PAG material in the management ponds once the PAG material has reached its design elevation. Non-PAG rock will be placed in lifts into water, keeping the water level at least 1 metre above PAG rock and at or below the non-PAG placement platform. A 1.5 metre thickness was selected for non-PAG as this is below the expected change in water levels during the Post-closure phase so that this material is never above water.



Overburden will be stored in the buttresses during operation and used as a cover material over non-PAG rock placed in the management ponds.

2.3.3 Management of Processed Rock

Coarse and fine processed rock materials are expected to be PAG and will also be placed in the Management Ponds with the PAG rock (Figure 2-3).

2.3.4 Open Pit Walls

Most of the open pit will be backfilled during the Operation phase. However, a small portion of the hanging wall will exist at post-closure. Meteoric water contacting the open pit walls will report to the end pit lakes, with one of them draining northwards by gravity and mix with Management Pond water prior to discharging into the surrounding environment while the other one discharges to Four Creek once its water quality meets regulatory requirements. Until this time, this end pit lake also drains toward the north.

3 Conceptual Model

3.1 Unsaturated Mine Rock & Processed Rock

Pyrite (FeS_2) is the main sulfide mineral in PAG rock and processed rock at the Project (SRK 2022b). Under natural conditions, pyrite is stable in bedrock where it is isolated from atmospheric oxygen. However, following blasting and excavation of the bedrock, pyrite in the rock mined will be exposed to atmospheric oxygen prior to being placed in the management ponds and will begin to oxidize producing sulfate, ferrous iron, and acidity (Rxn1).

$$FeS_{2\,(s)} + \frac{7}{2}O_{2\,(g)} + H_2O_{\,(l)} \leftrightarrow Fe^{2+}{}_{(aq)} + 2SO_4{}^{2-}{}_{(aq)} + 2H^+{}_{(aq)} \text{ (Rxn 1)}$$

Under oxidizing conditions, ferrous iron liberated during sulfide oxidation will subsequently oxidize to ferric iron in neutral pH producing additional acidity according to the following reaction:

$$Fe^{2+}{}_{(aq)} + \frac{1}{4}O_{2\,(g)} + 2\frac{1}{2}H_2O_{\,(l)} \leftrightarrow Fe(OH)_{3\,(s)} + 2H^+{}_{(aq)} \text{ (Rxn 2)}$$

Although oxidation of mine rock and processed rock for the Project will release acidity, acidic conditions are not predicted to occur immediately since these materials also contain carbonate minerals that will neutralize the acid according to the following reactions:

$$CaCO_{3(s)} + H^+{}_{(aq)} \leftrightarrow HCO_3{}^-{}_{(aq)} + Ca^{2+}{}_{(aq)} \text{ (Rxn 3)}$$

$$CaCO_{3(s)} + 2H^+{}_{(aq)} \leftrightarrow H_2CO_{3(aq)} + Ca^{2+}{}_{(aq)} \text{ (Rxn 4)}$$

Depletion calculations (SRK 2022b) indicate that the lag times to acid generation are on the order of years (>5 years based on the average bulk rock properties). The lag time to acid generation prediction based on HCTs was confirmed by the barrel testing results. Barrel 6, which is a composite sample of rock from Zones 6 and 7, became acid generating in October 2023, four years after the barrel program was initiated. SRK (2022b) indicated that these zones were non-PAG based on their average bulk geochemical properties. However, the weighted barrel 6's NPR (0.5) was more closely aligned with the minimum and P5 NPR observed for these zones (see Table 4 in SRK (2022b)). The lag times to the onset of acid generation based on the Zone 6 and 7 minimum NPRs ranged from 3 to 5 years.

TML proposes to place PAG rock identified by verification testing and processed rock in the management ponds under saturated conditions within an average of six months after blasting but no more than 12 months. Theoretically, this will limit sulfide oxidation (i.e., oxygen becomes a limited reactant in reaction 1 limiting oxidation of the PAG rock and coarse and fine processed rock precluding acidic conditions at the Project. However, any oxidation products that are produced prior to placement of PAG rock and processed rock underwater will be flushed and dissolve in water stored in the management ponds.

At closure TML will cap saturated PAG rock and coarse and fine processed rock in the management ponds with non-PAG rock. The non-PAG rock will be below the active water level in the management ponds and will be saturated. Any oxidation products that have accumulated on non-PAG rock surfaces will also be flushed when the rock is placed in the management pond.

3.2 Unsaturated Non-PAG Rock

Non-PAG rock that is not used in the management pond cover will be used to backfill the open pit and used in portions of the embankments and buttresses with approximately 50% remaining unsaturated in

post-closure. Under these conditions, the rock will continually oxidize according to Reaction 1 (see Section 3.1) producing oxidation products that will be dissolved in meteoric water contacting the rock. However, non-PAG rock contains more neutralization potential than acid generating potential and the sulfide is predicted to be consumed prior to the neutralization potential (SRK 2022b) and acidic drainage from exposed non-PAG rock will not occur. The non-PAG rock will provide a continuous source of element load under neutral conditions.

3.3 Overburden

Overburden that is stripped during mining will be mixed with unsaturated waste rock for use in the buttresses and open pit backfill. Overburden has been characterized as having low sulfur content (SRK 2022b) and is classified as non-PAG. The small amount of sulfide in the overburden will oxidize according to Reaction 1 producing oxidation products that will be solubilized by incident precipitation. Like unsaturated waste rock, the overburden will provide a continuous source of element load that is soluble under neutral conditions.

3.4 Open Pit Wall Rock Runoff

Mining of the Tenas Project will result in open pit walls that are exposed to atmospheric oxygen until they are progressively covered with non-PAG rock and/or overburden during the Operation phase with any remaining uncovered open pit walls being covered in the Decommissioning and Reclamation phase. Sulfides that are present in the open pit wall rock will oxidize according to reaction 1 (Section 3.1) producing sulfate, acidity, ferrous iron, and release of trace chalcophile elements. Soluble oxidation products will be flushed from exposed open pit wall surfaces in meteoric water contacting the wall rock.

The open pit will be progressively backfilled with non-PAG rock and/or overburden during operations reducing the exposure of open pit wall to atmospheric oxygen. Oxidation of open pit wall rock that is covered with backfill will be reduced by limiting oxygen ingress.

At closure, two end pit lakes will form in the backfilled open pit. A footwall will exist above the end pit lakes composed mainly of Zone 6 sedimentary rock. Based on the site-specific NPR criterion (2.0), this unit PAG; however, as discussed in Section 2.3.4, the majority of the exposed pit walls will be covered. The end pit lake will be a mixture of wall rock runoff, direct precipitation and runoff from non-PAG backfill.

The pit lake will drain by gravity and mix with the Management Pond before being discharged during closure.

3.5 Processed Coal Stockpile Runoff

Processed coal will be temporarily stored at the Rail Infrastructure area in two stockpiles prior to being transported from the site to Ridley terminals. While the processed coal is stored, it will oxidize but long-term oxidation is not a concern since processed coal will only be stored for short durations prior to being loaded into rail cars. Soluble load from the processed coal stockpiles will be collected in the Rail Infrastructure Sedimentation Pond to allow suspended solids to settle.

4 Source Term Derivation Methods

Consistent with SRK (2022b), source terms using the barrel testing results were developed in two ways: concentrations and load flushing rates. Unsaturated mine rock, overburden and wall rock runoff source terms were expressed as concentrations. Concentrations were estimated by scaling barrel testing results and mixing estimated annual loads in predicted annual volumes of water and evaluating if the predicted concentrations would be limited by secondary mineral precipitation. PAG rock, coarse and fine processed rock and some non-PAG rock will be stored permanently underwater in the management ponds. Solute produced through oxidative weathering once these materials have been exposed will be flushed from rock surfaces when they are placed in the management ponds. The source term for these materials is therefore represented by a flushing term in milligrams per bank cubic metre (mg/bcm) of rock, also estimated using scaled barrel testing results.

Processed rock (e.g., coal and rejects) barrels were not constructed since there was insufficient material available. Source terms for coal and rejects have therefore not been updated. The reader is referred to SRK (2022a) for the coal and reject source terms. The particulate concentrations source term has also not been updated since it is independent of kinetic testing release rates (i.e., it was derived based solid-phase static testing results) and is not included in this report. The reader is referred to SRK (2022a) for details on the derivation methods and results of these source terms.

The following subsections provide the inputs and assumptions for each of the source terms based on the barrel testing results.

4.1 Mine Rock Solute Release Rates

A key input into the source term calculations is the mine rock solute release rates. Barrels were constructed from rock representative of each rock zone and the barrel release rates were used to represent the release rates from individual rock zones. Composite samples for each barrel were prepared from excess sample stored at Bureau Veritas Laboratories in Burnaby, British Columbia. Sample, varying in mass from one to 110 kg were selected for use in the barrels until a minimum mass of 200 kg was achieved. Zones with insufficient sample mass to achieve 200 kg (e.g., Zone 4 PAG and Zone 4 non-PAG) were supplemented with sample from other zones with similar geochemical properties (SRK 2024b).

Leachate sampling from the barrels has been conducted intermittently since October 2019 until present. The source terms only consider samples collected until November 2023. Seven to nine samples have been collected from each barrel during this period. The monitoring results from these sampling events was used to estimate barrel release rates according to the following formula:

$$L_j = C_j * \frac{V}{m} / t \qquad \text{(EQ 1)}$$

Where:

L_j is the load of parameter j expressed in mg/kg/week

C_j is the concentration of parameter j in the leachate sample in mg/L

V is the volume of the sample in L

m is the total mass in the barrel in kg

t is the time between sample events in weeks

The average release rate calculated from each sampling event was used in the source term calculations. As noted in Section 3.1, Barrel 6 began to produce acidic leachate in October 2023. Release rates from this sampling event were not included in the average barrel release rate calculations since the conceptual model for the Project is rock will be managed to minimize acid generation and release rates under acidic conditions are not expected to occur.

As noted above, the barrels were constructed of crushed drill core. This results in the barrel samples having a higher reactive surface area in comparison to rock that will be blasted and used in the pit backfill or construction of the buttresses. Scaling factors were applied to the barrel release rates to account for this difference. Details of the scaling factors that were used are discussed in the following subsections.

4.2 Unsaturated Mine Rock and Overburden

4.2.1 Base Case Source Term

Unsaturated non-PAG rock and overburden will be used as backfill in the open pit as well as in construction of the management pond buttresses. The backfill will become partially saturated as the open pit floods at closure. Unsaturated portions of the backfill will continue to oxidize and produce soluble load that will be mobilized in meteoric water interacting with the mine rock.

Annual unsaturated mine rock concentrations were estimated as follows:

$$C_{j=\frac{L_{j,annual}}{Q_{annual}}} \quad \text{(Eq 2)}$$

Where: C_j is the concentration of constituent j

$L_{j,annual}$ is the annual load of constituent j released from exposed mine rock and/or overburden

Q_{annual} is the annual average flow contacting exposed mine rock and overburden

Source term concentrations using Equation 2 were estimated for the following timeframes:

- Pit Backfill
  - End of East Management Pond (EMP)
  - End of Mining (EOM)
- Buttresses
  - End of North Management Pond (NMP)
  - End of EMP
  - End of West Management Pond (WMP)

These periods were selected to evaluate changes to water quality throughout the life of mine (LOM) at key stages of the mine development. In the source term calculations, mine rock and overburden present in the above timeframes was assumed to be unsaturated and produce soluble load. In reality, a portion of the waste rock will become inundated as the pit is progressively backfilled. This assumption results in a conservative estimate of the pit backfill and buttress drainage water quality.

The mine plan indicates that the buttresses will be constructed using overburden and mine rock sourced from Zones 1 and 4. Table 4-1 provides a summary of the cumulative mine rock and overburden volumes and tonnages associated with each of the model timeframes. Mine rock tonnages were estimated using an assumed density of 2.55 grams per bank cubic centimetre (g/bcc) and a density of 2.0 g/bcc was assumed to estimate overburden tonnages (TML 2024, pers. comm.). The respective barrel release rates were prorated in proportions estimated based on the volumes provided in Table 4-1 to estimate the unit solute release rates for the backfill and buttresses at each of the model timeframes. This rate was multiplied by the total mass at each timeframe to estimate the annual load produced.

As noted in Section 4.1, scaling factors were applied to the barrel release rates to account for testing and operational field differences. A generic scaling factor of 0.2, based on SRK's experience at other coal mines in British Columbia, was applied to account for grain size differences between the barrel tests and mine rock that will be produced during operations. Channelization and temperature scaling factors, which were applied to the HCT release rates (SRK 2022b), were not applied to the barrel release rates. Due to the size of the tests, the barrels will have a higher degree of flushing in comparison to rock stored in the backfill and in the buttresses and additional channelization is expected to occur under operational conditions. It is difficult to quantify the degree of flushing in the barrels and a channelization factor was conservatively not included in the barrel release rate estimates.

The barrels only contain 200 kg of material and will therefore be more susceptible to temperature variations in comparison to the rock and overburden used in the backfill and buttresses which will exhibit internal heating from sulfide oxidation. However, the average temperature of the water samples collected from the barrel tests was approximately 10°C. It is assumed a similar internal temperature will occur in the mine rock backfill and buttresses from oxidation of sulfide minerals and carbonaceous rock and release rates were therefore not corrected for temperature differences.

Table 4-1. Summary of Unsaturated Mine Rock & Overburden Quantities

Facility	Cumulative Volume (bcm)			Cumulative Tonnage (Mt)		
	Mine Rock		Overburden	Mine Rock		Overburden
	Zone 1	Zone 2		Zone 1	Zone 2	
Backfill						
End of EMP	279,370	812,529	500,000	0.7	2.7	1.0

The annual scaled release rate was divided by the annual average volume of water contacting unsaturated mine rock (SRK 2024a) using Equation 2 to estimate the annual average constituent concentrations in drainage from unsaturated mine rock and overburden. Predicted water qualities were entered into the publicly available speciation and mass transfer code PHREEQC v.3 (Parkhurst and Appelo 1999), developed by the United States Geological Survey (USGS), to evaluate mineral and gas phases that were supersaturated in solution. The mineral and gas phases included in the model are presented in Table 4-2. Supersaturated mineral phases were allowed to precipitate from solution and

sorption to ferrihydrite was also considered using the default values of Dzombak and Morel (1990). Sorption to ferrihydrite will limit parameters that form oxyanions (e.g., arsenic) and other ligands from remaining in solution.

Table 4-2. Model Equilibrium Phases

Mineral	Empirical Formula	Mineral	Empirical Formula	Mineral	Empirical Formula
Carbon Dioxide	CO_2 (g)	Chalcanthite	$CuSO_4 \cdot 5H_2O$	Calcium Molybdenum Oxide	$CaMoO_4$
Gibbsite	$Al(OH)_3$	Ferrihydrite	$Fe(OH)_3$	Nickel Hydroxide	$Ni(OH)_2$
Otavite	$CdCO_3$	Melanterite	$FeSO_4 \cdot 7H_2O$	Zinc Hydroxide	$Zn(OH)_2$
Brochantite	$Cu_4SO_4(OH)_6$	Anglesite	$PbSO_4$	Smithsonite	$ZnCO_3$
Copper Hydroxide	$Cu(OH)_2$	Birnessite	$MnO_2 \cdot nH_2O$	Goslarite	$ZnSO_4 \cdot 7H_2O$
Malachite	$Cu_2(CO_3)(OH)_2$	Manganite	MnO(OH)	Gypsum	$CaSO_4 \cdot 2H_2O$
Azurite	$Cu_3(CO_3)_2(OH)_2$	Lead Molybdenum Oxide	$PbMoO_4$		

4.2.2 High Case Source Term

To account for variability in the source term inputs, a high case source term was developed. The high case source term was estimated by increasing sulfate concentrations to concentrations that are in equilibrium with gypsum (i.e., sulfate concentrations are assumed to be saturated in solution) under the assumed pH and redox conditions. Equilibrium with gypsum was achieved by incrementally adding anhydrite ($CaSO_4$) to the predicted base case solution (Section 4.2.1) until sulfate concentrations reached steady state. Concentrations of other elements were scaled up in the high source term by preserving the metal sulphate ratios (M/SO_4) in the base case source term. A key assumption in this approach is that elements in the solution are chalcophile which could result in an overprediction of non-chalcophile elements. Mineral saturation was evaluated by equilibrating the high case unsaturated mine rock water quality with the same mineral phases (Table 4-2) as the base case solution.

4.3 Saturated Mine Rock

4.3.1 PAG Rock Flushing Source Term

PAG rock produced during mining of the Tenas deposit will be permanently stored in saturated conditions in the management ponds. Placement of PAG rock in the management ponds will result in flushing of oxidation products accumulating on the surfaces of the PAG following exposure during mining. A unit annual flushing rate, in kilograms per tonne of rock (kg/tonne), was estimated by proportioning scaled barrel solute release rates (Section 4.1) in the relative proportion of each zone to be mined in each year (Table 4-3). The same grain size factor used to estimate loadings from unsaturated waste rock (Section 4.2.1) was applied to estimate the mass flushed from PAG rock.

A key input to the PAG rock flushing source term is the exposure time prior to placement in the management ponds. TCL proposes to have PAG rock including processed rock placed in the management ponds within an average of six months which was used when developing the PAG rock flushing source term. Like the unsaturated mine rock source term, a high case was also developed where PAG mine rock was assumed to be exposed for 12 months.

Table 4-3. Annual PAG Rock Volumes and Relative Proportions

Year	Mine Rock Volume (bcm)								Mine Rock Proportion						
	Zone 1a	Zone 2	Zone 3	Zone 4 (PAG)	Zone 5	Zone 55	Zone 6	Total	Zone 1A	Zone 2	Zone 3	Zone 4 (PAG)	Zone 5	Zone 55	Zone 6

4.3.2 Non-PAG Rock Flushing Source Term

As PAG material reaches its designed elevation, non-PAG rock will then be placed in lifts above the saturated PAG. Once this lift is completed, overburden is then placed in a maximum of a 3 metre lift to form dry land reclamation. Surface soils will then be placed in a lift thickness of approximately 30 centimetres. The non-PAG rock will be placed in aqueous conditions and the majority of the overburden will be unsaturated. Oxidation products that have accumulated on the non-PAG mine rock following exposure during mining will be flushed from the surfaces as the rock is placed in the management pond.

TML proposes to use non-PAG rock source from Zone 1 in the management pond cover. A unit flushing rate, in kg/tonne, was estimated by scaling the Zone 1 average barrel release rates results to account for differences between testing and operational field conditions. The same scaling factor used to estimate the PAG rock flushing term was applied (i.e., grain size factor). Flushing rates were estimated for six- and 12-month exposure periods.

4.3.3 Flooded non-PAG Rock Backfill

Approximately 50% of the non-PAG rock in the backfill will become flooded in Post-closure. Mass that accumulates in the backfill will be flushed during flooding. As discussed in Section 4.2.1, unsaturated mine rock is not assumed to have a channelization factor and is assumed to have a high leaching efficiency since there is uncertainty in quantifying the degree of channelization in the barrel tests. This provides a conservative estimate of the drainage quality from unsaturated materials, but no mass accumulation will occur using this approach. Therefore, flushing of submerged mass is not accounted for in the source terms.

The water balance model (SRK 2021) indicates there is no hydraulic connection of water stored in the flooded backfill to the management ponds. However, a small volume of the flooded backfill water will report to the groundwater system. Water balancing modelling indicates that the water losses from the flooded backfill represent less than one percent (i.e., 0.4%) of the total flow to the groundwater system. As noted above, there is a high degree of uncertainty in estimating the residual load that will be flushed from the flooded backfill and since the flow is effectively negligible to other flows, a source term was not developed for the flooded non-PAG rock backfill.

4.4 Wall Rock Runoff

Exposed wall rock surfaces will produce oxidative load that will be flushed by meteoric water. An annual pit wall drainage water quality was estimated using equation 2; however, in this instance $L_{j,annual}$ is the annual load of constituent j released from exposed wall rock surfaces and Q_{annual} is the annual average flow contacting the exposed wall rock. TML proposes to progressively backfill the open pit during operations. This will continually change the areas of rock exposed in the pit walls. To evaluate changes to the wall rock runoff composition, source terms were developed for the following time periods, which correspond to backfilling of different areas and volumes placed in the open pit:

- End of placement of PAG rock in the North Management Pond (NMP)
- End of placement of PAG rock in the East Management Pond (EMP)
- End of the Operation Phase (EOM)

The reactive mass of each stratigraphic zone in the open pit walls was estimated by multiplying the exposed surface area of each of the zones in the open pit walls by an assumed depth of fractured rock for each of the above time periods. Surface areas for each time period are provided in Table 4-4. The fractured rock depth was assumed to be two metres for blasted areas and five centimetres for free dig areas and the floor of the pit. A density of 2.55 g/cc was assumed to estimate the reactive mass exposed in the pit walls.

The average release rates from each barrel were prorated in relative proportions calculated based on the exposed surface areas (Table 4-4) to estimate the unit solute release rates for the backfill. As discussed in Section 4.1, barrels tests are not available for processed rock. The approach described in SRK (2022a) was used to represent loadings from exposed coal seams. This rate was multiplied by the total reactive mass in the open pit walls to estimate the annual load produced. The annual load was scaled to field conditions using the grain size differences. Since HCT release rates were used to represent release rates from exposed coal seams, a temperature factor was applied to coal (SRK 2022a). It was assumed that the entire fractured rock zone in the open pit walls would be flushed, and a channelization factor was not included.

The annual scaled release rate was divided by the annual average volume of water contacting wall rock runoff (SRK 2022) to estimate drainage concentrations using equation 2. The annual volume for each time period is presented in Table 4-5. Mineral solubility was evaluated and phases that were identified to be supersaturated in solution were allowed to precipitate or off-gas (for gas phases). Mineral phases that were considered are provided in Table 4-2. Sorption to ferrihydrite was also included when this mineral phase precipitated.

Like the unsaturated mine rock source term, a high case wall rock source term was estimated by forcing the predicted solutions to gypsum saturation through incremental anhydrite addition in PHREEQC. Element sulfate ratios in the base case source term were assumed when calculating concentrations of other constituents. The scaled-up solution was subsequently equilibrated with the mineral phases presented in Table 4-2 and sorption to ferrihydrite was permitted when this mineral phase precipitated.

During operations it is assumed that the pit backfill will be fully oxygenated. Therefore, the wall rock that is below the backfill will also be reactive. A load from the backfilled pit walls was also estimated using the same assumptions as exposed wall rock. The annual load originating from covered walls at the end of EMP and EOM was added to unsaturated mine rock load (Section 4.2). The load was estimated by prorating the scaled barrel loads (and HCT for exposed coal seams) in proportions calculated based on the backfilled pit wall surface areas (Table 4-6).

5 Source Terms

The following sections present the Tenas Project source terms. The source terms do not represent discharge water quality and how the mine rock flushing source terms influence site drainage water quality cannot be quantified until they are carried forward into the site wide water and load balance. Therefore, limited interpretation of the source terms is included in the following sections. Detailed interpretations of the site wide water and load balance model results using these source terms are included in SRK (2024a).

5.1 Unsaturated Mine Rock & Overburden

5.1.1 Pit Backfill Source Term Water Quality

The base case and high case pit backfill source terms for end of EMP and EOM are provided in Table 5-1. The charge imbalance for the base case and high case solutions were less than 10%. This is considered acceptable for a modelled solution that have average inputs from multiple sampling rounds and charge imbalances were not corrected. The pH of solutions is alkaline (8.2 to 8.5) and all modelled constituent concentrations are higher in the high case in comparison to the base case source terms since gypsum was not predicted to be supersaturated in the base case source term and the scaling method (i.e., preserving element/sulfate ratios; see Section 4.2.2) results in constituent concentrations being higher in the high case solutions. Predicted constituent concentrations are higher at the EOM in comparison to the end of EMP source terms because of increased reactive mass in the pit backfill (Table 4-1).

Table 5-1. Pit Backfill Source Term Water Quality

Parameter	Units	Non-PAG Backfill - End of EMP		Non-PAG Backfill - End of EOM

5.1.2 Dam/Buttress Source Term Water Quality

The base case and high case dam/buttress source term water quality for end of NMP, end of EMP and end of WMP are provided in Table 5-2. The charge imbalance for the base case and high case solutions were less than 10%. This is considered acceptable for a modelled solution mixing average inputs from multiple HCTs and charge imbalances were not corrected. The pH of solutions is alkaline ranging from 7.6 to 8.3.

The trends in predicted concentrations are like the pit backfill water quality. For example, the modelled constituent concentrations are higher in the high case in comparison to the base case source terms since gypsum was not predicted to be supersaturated in the base case scenario. Constituent concentrations are predicted to increase throughout the LOM because of the reactive mass increasing (Table 4-1).

Table 5-2. Dam/Buttress Source Term Water Quality

Parameter	Units	Dam/Buttress Infiltration - End of NMP		Dam/Buttress Infiltration - End of EMP		Dam/Buttress Infiltration - End of WMP

5.2 Saturated Mine Rock

Saturated rock flushing terms are presented in kg/tonne. The influence of flushing of rock as it is placed in the management ponds cannot be quantified until it is carried forward into the water and load balance. Annual PAG rock flushing rates for the six- and 12-month exposure periods are provided in Table 5-3 and Table 5-4, respectively. The non-PAG rock flushing source terms are provided in Table 5-5, respectively.

Table 5-3. PAG Rock Annual Flushing Source Term – Six Month Average Exposure

5.3 Open Pit Wall Rock Runoff

The base case and high case open pit wall rock runoff source terms for the End of NMP, End of EMP and EOM are provided in Table 5-6. The charge balance in of the wall rock source terms is less than 10%, which is considered reasonable for solutions based on averaging several release rates in the field barrel tests. The pH of solutions was alkaline (7.4 to 8.1) and maximum pit wall runoff concentrations occurred at the end of the EMP since this timeframe represents the maximum exposure of pit wall and has the highest reactive mass (Table 4-6).

Most of the constituents were higher in the high case source term in comparison to the base case. Concentrations of iron were lower in the high case source terms. Iron concentrations are low in both scenarios since it is solubility constrained through ferrihydrite ($Fe(OH)_3$) precipitation. Lower iron concentrations occur in the high case source term since these solutions are more alkaline reducing the ferrihydrite solubility (i.e., more ferrihydrite is predicted to precipitate in the high case scenario).

6 Summary

SRK (2022a) developed geochemical source terms by scaling HCT testing results to field conditions. A comparison to the scaled HCT and barrel testing results indicated that the release rates of some constituents are higher in the barrels in comparison to the HCT. The geochemical source terms were updated using the barrel release rates. The barrel release rates are considered more appropriate for estimating site drainage water quality because they are more representative of solute release rates under field conditions.

Barrels were constructed using mine rock sample rejects and overburden. Insufficient processed rock (e.g., coal, coarse rejects, etc.) sample precluded barrels being constructed for these materials. Base The following source terms were updated using the barrel testing results:

- Unsaturated non-PAG & overburden
  - Pits backfill
  - Dams/buttresses
- Saturated non-PAG rock
- Saturated PAG rock
- Open pit wall rock runoff

The following source terms were not updated and the SRK (2022a) source terms remain current:

- Processed rock
- Processed coal stockpile runoff
- Particulate concentrations

The above source terms will be carried forward into the site wide water and load balance to evaluate the mixed project discharge water quality. To evaluate uncertainty in the model, both the base case and high case scenarios should be evaluated.

EXECUTIVE SUMMARY

Okane Consultants (Okane) are providing support to evaluate the development of suboxic conditions for the backfill of non-potentially acid generation (NAG) mine rock into the Open Pit for Telkwa Mining Limited (Telkwa) at their proposed Tenas Project in northwest British Columbia. The current scope focuses on placement of NAG mine rock. The objective of the scope was to develop geochemical source terms for the backfilled mine rock that reflect the construction and reclamation schedule, and the resulting hydrological and oxygen conditions of the backfill.

The source terms were developed using a two-dimensional oxygen model to evaluate the size, location, and timing of suboxic (low oxygen concentration) conditions within the NAG backfill. The formation of suboxic conditions limits oxidation rates of sulfide minerals and decreases the loads of constituents of interest released from sulfide oxidation to the receiving environment. The source terms will be used as inputs for the site-wide water quality model that integrates seepage and chemical loads from all mine domains to understand the overarching water quality effects of the Project on the receiving environment. All years presented herein refer to mine plan years.

Three scenarios were chosen to evaluate the development of suboxic conditions. The three scenarios were:

- Scenario #1: Poorly graded till and sandstone mine rock;
- Scenario #2: Well graded till and mine rock mix (60% siltstone, 35% mudstone, and 5% sandstone);
- Scenario #3: Well graded till and mine rock mix (60% siltstone, 35% mudstone, and 5% sandstone) with no internal cover layers.

During the covered time period for all modelled scenarios, two sequential cover surface conditions (grass cover followed by the establishment of mature forest) were used to simulate the maturing of vegetation on the cover system. These surface conditions affected how oxygen and water move into the cover material and underlying NAG backfill. For a five-year period directly after cover placement the simulation used a grass surface; following this five-year period, a forest surface was used for the remainder of the model timeframe.

GoldSim seepage modelling for the NAG backfill demonstrated a significant reduction in stabilized seepage rates between the modelled scenarios. Stabilized seepage rates for Scenarios #2 and #3 were approximately half of the stabilized rates for Scenario #1. The modelling also demonstrated that the NAG backfill will be wetted up after approximately 40 years in Scenario #1 and approximately 80 years in Scenarios #2 and #3 due to differences in material texture in the cover system. Modelling demonstrated that suboxic conditions within Scenario #1 took approximately 15 years to develop and approximately 13 years in Scenarios #2 and #3 once the cover system was placed. Depths to suboxic conditions varied between the scenarios due to differences in oxygen ingress and net percolation. Scenario #1 had a

long-term depth to suboxia of approximately 15 m while Scenarios #2 and #3 had a long-term depth to suboxia of approximately 3 m.

Estimated stored water volumes increase as mine rock is placed during construction and stabilize after approximately 15 years when construction has ended. Similar to seepage results, the stored water volumes stabilize after approximately 40 years for Scenario #1 and 70-80 years for Scenarios #2 and #3. Stored water volumes in the NAG backfill are predicted to be lower in Scenarios #2 and #3 relative to Scenario #1.

Source terms were developed for Scenarios #1, #2, and #3 using a reactive transport modelling approach. Reactive transport modelling was used to simulate the weathering of sulfide and carbonate minerals and resulting concentrations of related dissolved constituents using mechanistic kinetic weathering rates controlled by the geochemical setting of the NAG backfill. For constituents not directly controlled by sulfide oxidation and carbonate dissolution, a constant loading rate scale-up model was used to develop source terms. The geochemical models were calibrated to on-site kinetic barrel tests containing NAG mine rock and subsequently applied to the full-scale NAG backfill geometry.

The geochemical model incorporated changing cover system surface conditions by changing net percolation into the model for each time period (bare mine rock, grass coverage, and forest coverage). The effects of suboxic zones were simulated by limiting pyrite oxidation to depths where oxygen models simulated oxic conditions.

In general, concentrations for modelled parameters were similar between all scenarios. Although it was evident that less pyrite oxidation was occurring in the Scenario #2 and #3 models due to the larger suboxic zones, which resulted in lower mass release of oxidation products, decreased infiltrating water volumes (i.e., less dilution) in these scenarios resulted in similar concentrations as seen in Scenario #1. The primary benefit of the well-graded cover system scenarios is the overall decrease of released load of oxidation products (e.g., selenium and sulfate) from the NAG backfill. Scenarios #2 and #3 consistently had lower chemical loading relative to Scenario #1 resulting in approximately half the mass of oxidation products released from the NAG backfill on an annual basis. Scenarios #2 and #3 had similar chemical loading due to similar lag-times to suboxic zone development and depth to suboxic conditions. Additionally, geochemical source terms of the NAG backfill from the current model were comparable, although generally slightly lower, than source terms initially developed for the backfill (SRK, 2022a). The NAG backfill source terms from this modelling work will be integrated into the site wide load balance model to quantify the effects of the backfill on water quality around the Tenas project.

1 INTRODUCTION

1.1 Project Description

Telkwa Mining Limited (Telkwa) are proposing to develop the Tenas Project (Project), located approximately 25 km southwest of the town of Smithers in northwest British Columbia (BC) within the Telkwa and Bulkley River watersheds. The Project consists of an open pit, backfill, external stockpiles, water management ponds, control ponds, coal processing plant, and rail infrastructure. Elevation of the Project ranges from 750 to 1,050 meters above sea level (masl), with a median elevation of 800 masl. The Project is within the Ministry of Environment and Climate Change Strategy (MECCS) Zone 8 – Nechako Plateau, close to the border with Zone 9 – Southern Hazelton Mountains (Ahmed and Jackson, 2013). The MECCS hydrological zones are areas of homogeneous hydrologic and geomorphic characteristics.

1.2 Project Objectives and Scope

Okane Consultants (Okane) is providing support to develop source terms for three scenarios of backfill NAG mine rock in lifts using bottom-up construction methodology with overburden covers within the Open Pit provided by Telkwa. The objective of the backfilled design is to limit oxygen and water ingress to minimize the release of potential contaminants of concern such as selenium and sulfate to the receiving environment.

A geochemical model that incorporated both a mechanistic reactive transport model and geochemical scale-up model was developed to simulate long-term water quality of mine rock backfilled into the Open Pit. Seepage water quality results from the geochemical model were developed as source terms to be used in the Tenas site-wide water quality model developed by SRK Consulting (SRK).

1.3 Report Organization

For convenient reference, this report has been subdivided into the following sections:

- Section 2 – Provides pertinent background information for this study;
- Section 3 – Description of modelling processes;
- Section 4 – Modelling results and discussion; and
- Section 5 – Conclusions of the modelling work.

2 BACKGROUND

Source control of contaminants of interest (COIs) is a cutting-edge practice. It demonstrates a significant commitment to minimizing water quality impacts in the region to both regulators and stakeholders. Okane has extensive experience in implementing closure strategies to mine storage facilities, ultimately limiting oxygen ingress and net percolation into the underlying waste material. This working experience has led to development of fully integrated models that link hydrology, oxygen conditions, material properties, mine rock structure and climate to develop source terms for site-wide water quality models.

Okane's experience has shown that there are solutions available to improve source control and water quality, therefore, providing the opportunity to relinquish the site at the end of the mine life versus treating water from the mine rock into perpetuity. Such solutions can include progressive reclamation and the application of oxygen-limiting cover systems which can lead to the development of suboxia within the NAG mine rock storage facilities (MRSFs) to help improve long-term seepage quality by inhibiting the oxidation of sulfide minerals within the SOZ, decreasing the release and production of metal leaching in the lower zones of the MRSF.

Currently for the Project, suboxia is defined as pore gas oxygen concentrations less than 1 vol.%, which results in a dissolved oxygen concentration in pore water of less than 1 mg/L. The NAG mine rock is a large porous mass, which during placement will have oxygen concentration in pore spaces reflecting ambient conditions, or near to ambient conditions. Oxygen within NAG mine rock pore spaces will be depleted because of sulfide (pyrite) oxidation.

2.1 Net Percolation and Oxygen Ingress Classifications

The term 'net percolation' (NP) is used throughout this memo and is defined as presented in Figure 2.1. Precipitation (PPT) that reaches the cover system surface will either be intercepted by vegetation, run off (RO), or infiltrate into the cover system. A portion of the water that infiltrates will be stored in an active zone (ΔS) where water is actively cycled within the soil profile and into the atmosphere. Water stored in the active zone can be evaporated (AE) into the overlying atmosphere or can be removed by plant transpiration (AT); the combination of evaporation and transpiration is referred to as actual evapotranspiration (AET). Water in the cover system can also potentially move laterally as interflow. Water that moves below the active zone and is no longer available to be removed from the system via AET or laterally is defined as NP. NP is infiltrating water expressed as a percentage of average annual precipitation (PPT) that will migrate beyond the active zone because of gravity overcoming the influence of evapotranspiration, resulting in flow of water into the underlying NAG mine rock and overburden cover.

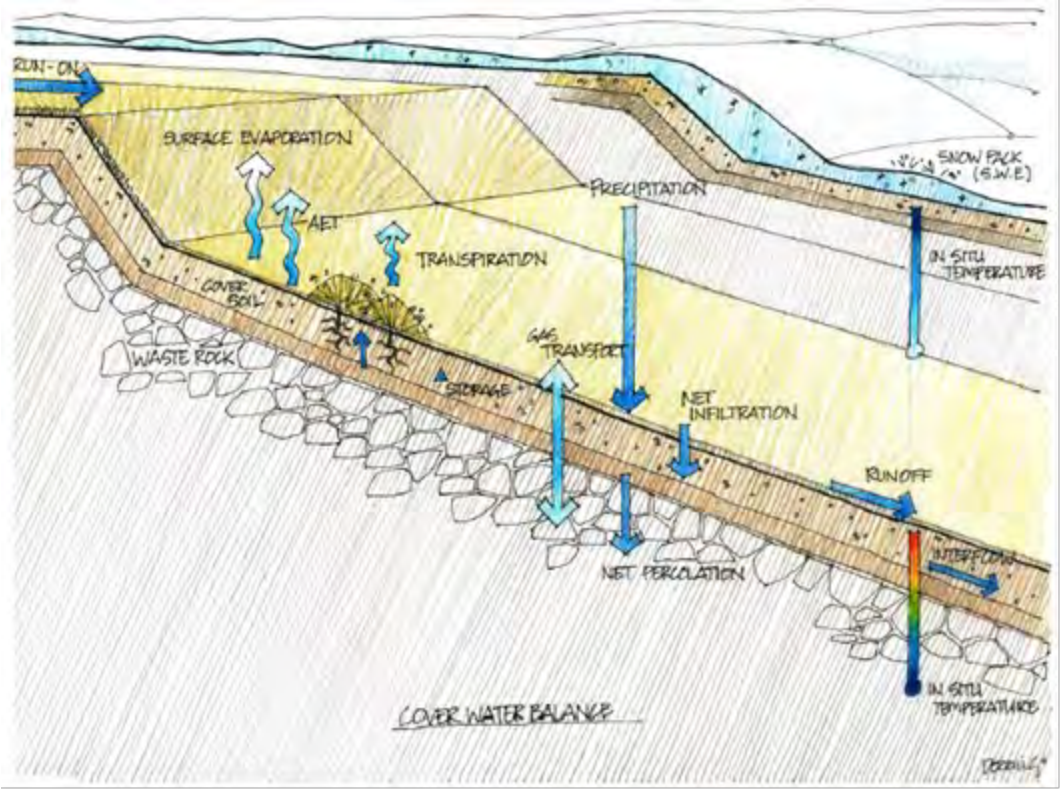

Figure 2.1: Schematic of hydraulic processes that influence performance of a cover system (from INAP, 2017)

As shown by the Project climate data described later in this report, the Project is classified as subarctic (Dfc) using the Köppen-Geiger climate classification (Peel *et al.,* 2007). Based on this classification, the range of cover system performance for the Tenas Project is presented conceptually, as defined in the Global Cover System Design Technical Guidance Document (INAP, 2017), as follows:

- "Very High" NP is greater than 50% PPT;
- "High" NP is between 25% PPT and 50% PPT;
- "Moderate" NP is between 15% PPT and 25% PPT;
- "Low" NP is between 5% PPT and 15% PPT; and
- "Very Low" NP is less than 5% PPT.

Within a single climatic regime, the same range of NP rates may be a result of the influence of differing abilities of a cover system to evapotranspirate water, and to promote runoff and interflow (i.e., lateral flow within the cover system) from the landform. Net percolation rates will also vary from year to year. For example, a high rainfall year (or, more specifically, several successive wetter than average climate

years) may result in a moderate net percolation rate for the year, even for a cover system scenario classified, on average, as having a low net percolation rate.

Cover performance with respect to oxygen (O_2) ingress can also be classified using the Global Cover System Design Technical Guidance Document (INAP, 2017) as follows:

- "Very High" O_2 ingress is greater than 100 mol/m^2/year;
- "High" O_2 ingress is between 50 and 100 mol/m^2/year;
- "Moderate" O_2 ingress is between 10 and 50 mol/m^2/year;
- "Low" O_2 ingress is between 1 and 10 mol/m^2/year; and
- "Very Low" O_2 ingress is less than 1 mol/m^2/year.

Limiting oxygen ingress is often achieved by limiting diffusion or restricting air flow by reducing pressure and/or thermal gradients. Usually, the most effective way to limit oxygen ingress is to create and sustain saturated conditions in a layer within the cover system. O_2 ingress is less challenging to limit in wetter environments where a tension-saturated layer is more easily maintained, and finer-textured material together with the tension saturated conditions will lead to reduced air permeability and therefore, advective gas transport. A similar range of performance exists for O_2 ingress as for NP where rates will vary from year to year. For example, a low rainfall year or several successive drier than average years will reduce the degree of saturation maintained within the cover system and may increase the predicted oxygen ingress rate for the year.

Limiting NP and O_2 ingress are not necessarily mutually beneficial and achieving reductions in either or both is site specific. Depending on available materials for cover system construction, limiting NP may result in less water available to maintain a saturated layer, whereas limiting O_2 ingress may require promoting additional NP. Hence, a technical assessment is required to make decisions on how best to optimize these two aspects to best take advantage of how each facet enhances performance for a particular project.

2.2 Site Specific Attributes

Assessment of the NAG backfill and cover system performance requires analysis of site attributes that constrain design alternatives to achieve the desired performance (INAP, 2017). The following site-specific attributes will be used to define performance of the NAG backfill design at Tenas:

- Climate;
- Hydrogeological setting;

- Materials;
- Vegetation; and,
- Geochemistry.

These key site attributes are described in the following sections based on background data provided by Telkwa.

2.3 Climate

The regional climate is a subarctic climate where winters are cold, averaging around -5°C during the period of November through February with temperatures potentially dropping to -30°C or colder, and summers are warm, with average temperatures greater than 20°C and highs of greater than 30°C are possible. Precipitation occurs as rain during the warmer months, accounting for 60-65% of annual precipitation. Snow accounts for 35-40% of annual precipitation with maximum accumulation of snow occurring in February-March.

The Project falls near the intersection of Dfc (subarctic climate) and Dsc (Mediterranean-influenced subarctic climate) of the Köppen-Geiger climate classification system (Peel *et al.*, 2007) where:

- D – 'continental' where average temperature of the coolest month is < -3 °C, and average temperature of the warmest month is > 10 °C;
- f – 'without dry season' where precipitation is evenly distributed throughout the year;
- s – 'dry summer' where precipitation of the driest month in summer is less than 40 mm and is also less than a third of the precipitation of the wettest month in winter; and
- c – 'cold summer' where one to three months average temperature reach >10 °C but < 22 °C.

2.4 Hydrogeological Setting

The results of historical hydrogeological investigations and *in-situ* testing are presented in Table 2.1. Surficial material is primarily sandy till to silty clay (Piteau, 1997), which is underlain by fractured sedimentary bedrock consisting of mudstones, siltstones, and sandstones (Klohn, 1985; Piteau, 1997; SRK 2018; 2019). *In-situ* hydraulic conductivity of the bedrock ranged from 6.0×10^{-6} m/s to 1.0×10^{-10} m/s.

Using the British Columbia Groundwater Wells Database, a search was completed, and 11 water wells were found in the vicinity of the mining operations. Nine domestic drinking water wells and two commercial water wells were found to be in the area N-NE of the mine site. Four of the wells are just south of the Telkwa River and west of Tenas Creek while the remaining seven (7) wells are east of Goathorn Creek. The range in finished depth of the water wells is 12 to 43 m below ground level (mbgl),

with a range of static head of 5.5 to 39 m below top of casing (btc), and an estimated yield range from 15 to 114 L/min.

Table 2.1 Record of hydrogeological investigations and *in-situ* testing.

Location and Geology	Hydrogeological Instrumentation	Groundwater Flow and Piezometric Surface	*In-Situ* Hydraulic Conductivity (K) and Linear Flow Velocity (V)
Telka Site (Klohn, 1985) Variable thicknesses of glacial till and gravel overlying sequences of sandstones, siltstones, mudstones, and coal. Bedrock dips 15-20 degrees to the east and is structurally dominated by several N-S trending reverse faults and normal faults which trend N-S and EW. Bedrock is of low permeability and contains no stratigraphically definable aquifers. The groundwater table is at or close to ground surface for much of the eastern part of the site. Breccia filled fault zones are expected to be significant conductors of groundwater.	16 piezometers installed (*none of the piezometers are still functional)	23 rural households within 3 km of the mine area obtain their domestic water supplies from groundwater, either by dug wells (2 to 6 m depth) or by drilled wells (less than 50 m depth) Domestic well records indicate that groundwater in the area is at about 12.5 m depth within a gravel layer.	Coefficient of permeability, Coal: 5×10^{-7} to 5×10^{-9} m/s Siltstone, Mudstone Sandstone: 2×10^{-7} to 1×10^{-10} m/s Recharge was estimated as 3% of annual precipitation based on the estimated groundwater flux and a value for hydraulic conductivity derived from the packer tests.
Tenas Pit (Piteau, 1997) Telkwa coal lease is underlain by coal-bearing sedimentary sequence comprising siltstone, sandstone, mudstone, and shale strata of the Lower Cretaceous age Skeena Group (Units 1-4). Economic coal seams in Unit 1 – 120 mm thick sequence of interbedded coal and sedimentary rocks. Faulting is near vertical, one group strikes ~NW/SE and other group strikes ~NE/SW. Few E/W striking faults. Surficial deposits are primarily till ranging from sandy silt to silty clay with minor gravel with range in thickness from less than 3 m to more than 10 m.	4 piezometers within coal seam #1 in 1995 5 piezometers in the major coal seams at three new locations in 1996	NE direction with horizontal hydraulic gradient of ~0.1. Flowing artesian conditions exist in all but 3 piezometers completed in coal seam #1.	K range of 2.1×10^{-8} to 6.0×10^{-6} m/s Average V is 115 m/year but does not consider local fault or fracture zones. V in the range of 10 to 250 m/year may be expected.

Location and Geology	Hydrogeological Instrumentation	Groundwater Flow and Piezometric Surface	*In-Situ* Hydraulic Conductivity (K) and Linear Flow Velocity (V)
Waste Dumps (Piteau, 1997) Waste dump sites underlain by till from 3.75 - 13.5 m thick. Thinnest till blanket is deposited directly on the bedrock surface and thickest till deposit overlies outwash sediments. East side of Tenas pit, thin 6.0 m till overlies permeable sands and gravels. Where overburden is more than 10 m thick, bedrock is overlain by high permeability sand and gravel outwash deposits. The thickest of which (106 m) is in the NW corner of the Tenas waste dump sites where a buried channel (clays, sands, and gravels) exists where the depth to bedrock exceeds 117 m. Bedrock from 4.6 - 117 m consists of either volcanic ash or interbedded sequences of siltstone and mudstone with occasional sandstone.	11 holes drilled at 9 locations	Interpreted to follow topography within surficial sediments between 0.5 - 2.0 m. Depending on location, shallow groundwater flow will either be in a northwesterly or northeasterly direction towards Tenas Creek or Four Creek. At one piezometer nest, strong downward vertical gradients indicative of groundwater recharge conditions exist between upper and lower water-bearing deposits. Due to upland topography of the waste dump sites, groundwater recharge conditions are expected to prevail.	Three single well response tests indicated K of the upper water-bearing till deposit to be in the range of 2.8×10^{-9} to 7.2×10^{-7} m/s. These values are low and thus vertical infiltration rates through this deposit would similarly be expected to be low.
Pit 3 (Piteau, 1997) Bedrock: alternating sequence of siltstone, mudstone, sandstone, and coal with sporadic volcanic tuffs throughout the sequence. Complex series of sub-parallel, N-S trending reverse faults and N-S, and to a lesser extend E-W, trending normal faults. Bedrock overlain by ~10 - 15 m of silty clay till with minor coarse fragments and sand.	5 piezometers installed at 3 locations in Pit 3. At each location, a piezometer was completed across coal seam #2 A second piezometer was installed across coal seam #4 at two locations.	Within coal units, groundwater flow is interpreted to be in a north to northwesterly direction. Horizontal hydraulic gradient of ~0.04. Depth to water ranged from 7.55 - 36.73 mbgs.	From one single well response test, K of coal seam #2 estimated at 4.3×10^{-10} m/s. From two single well response tests, K of coal seam #4 estimated at 8.5×10^{-7} m/s and 3.7×10^{-6} m/s. Average V in coal seams estimated range 20-100 m/year.
Mine rock dumps and sediment ponds (SRK, 2018)	13 sonic drillholes to depths between 9.0 m and 30.8 m upon reaching bedrock or sufficiently high soil density.	Two sonic piezometers were dry, one had water up to ground level and the last had a depth to water of ~14 m.	-

Location and Geology	Hydrogeological Instrumentation	Groundwater Flow and Piezometric Surface	*In-Situ* Hydraulic Conductivity (K) and Linear Flow Velocity (V)
	4 standpipe piezometers were installed for groundwater monitoring in 2017. 8 diamond drillholes with lengths from 70 m to 213.7 m were drilled. 3 of these drillholes had piezometers installed in them.		
Management ponds, sediment ponds, external soil/rock piles and infrastructure pad (SRK, 2019)	12 sonic drillholes were terminated at depths between 10.7 m and 67.1 m upon reaching bedrock. 12 standpipe piezometers were installed for groundwater monitoring in 2018.	The shallowest groundwater levels were approximately 14 mbgs but the piezometric table was located between 20 m and 40 m within the overburden soils.	-

2.5 Materials

Site-specific material characterization and availability are the two main elements for cover system design. Material selection and strategic placement is a key control on cover system performance and is used to provide a means for functions such as vegetation establishment, erosion control, and drainage where required in the cover system design (MEND, 2004).

Surficial deposits (overburden) within the Project Area are primarily till ranging from sandy silt to silty clay with minor gravel (and less than 5% cobbles and boulders) with a range in thickness over the Tenas Project Area from 4 m to 100 m (SRK, 2018). Recent drilling investigations (SRK, 2018; 2019) of the overburden material are in agreement with historical investigations (Klohn, 1985; Piteau, 1997) except for no sand and gravel outwash deposits in the northwest of the project site reported in Piteau (1997) being encountered in current drill holes (SRK, 2018; 2019). The till surface deposits will be excavated in the mining process and stockpiled for later use in the cover systems or direct placed from mining.

The bedrock in the Tenas Open Pit is of the early Cretaceous-aged Skeena Group and consists of alternating sequences of siltstone, mudstone, sandstone, and conglomerates with inter-bedded, bituminous coal seams (SRK, 2018). In Unit 1 a sedimentary sequence from 50 m to 120 m in thickness is interbedded with Coal Seam 1 (Seamas 1A-1F) with individual thicknesses of 1 m to 3 m (SRK, 2018). To access the inter-bedded coal layers, the bedrock will be excavated becoming mine rock to be placed in lifts and covered with the till material.

Particle size distribution (PSD) data was only available for the overburden till material and no information was available for the mine rock. The overburden material can be grouped into two categories based on the PSD data, a poorly-graded till and a well-graded till. Figure 2.2 shows the range of PSDs for each group based on the testing completed by SRK in 2019 (SRK, 2019). Following completion of sample compaction tests, four till samples were assessed for permeability, the results ranged from 1.04×10^{-7} m/s to 1.18×10^{-10} m/s (SRK, 2018).

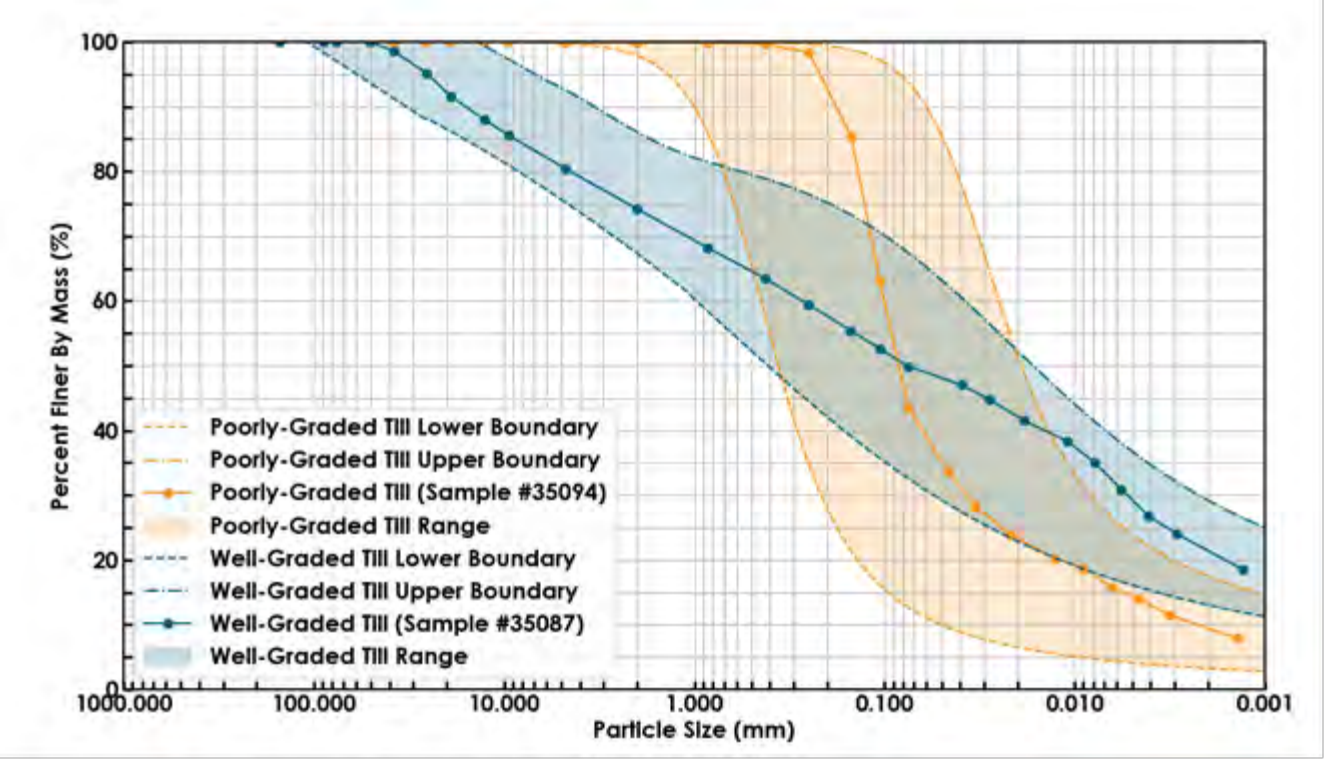

Figure 2.2: Range of PSDs for Poorly-Graded and Well-Graded Till based on SRK (2019).
(adapted from SRK, 2019)

2.6 Vegetation

The Project is located within the Sub-Boreal Spruce (SBS) zone of the biogeoclimatic zones of British Columbia. The dominant coniferous tree species in this zone include hybrid white spruce (hybrid of Engelmann spruce and white spruce), sub-alpine fir, lodgepole pine, and occasionally, black spruce and Douglas-fir (BC Ministry of Forests, 1998). Deciduous species include trembling aspen and paper birch.

2.7 Geochemistry

Non-potentially acid generating mine rock will be used as backfill into the Open Pit. Although sulfide minerals are present (and sulfide oxidation is expected), these materials contain an excess of neutralization potential (at least 2x) relative to the acid potential (AP) and are not expected to generate acidic drainage (Price, 2009). However, sulfide oxidation products will still be generated and transported through the mine rock by contact water. Concentrations of select dissolved trace metals and sulfate will be constrained by secondary mineral precipitation (e.g., gypsum and metal hydroxide phases) and adsorption to iron hydroxides that typically precipitate in circum-neutral mine waters. However, even with these solubility controls, metal loads from pyrite oxidation could still pose a risk to downstream

receptors. A conceptual model of geochemical reactions occurring along a typical flow path within the Tenas NAG mine rock is shown in Figure 2.3.

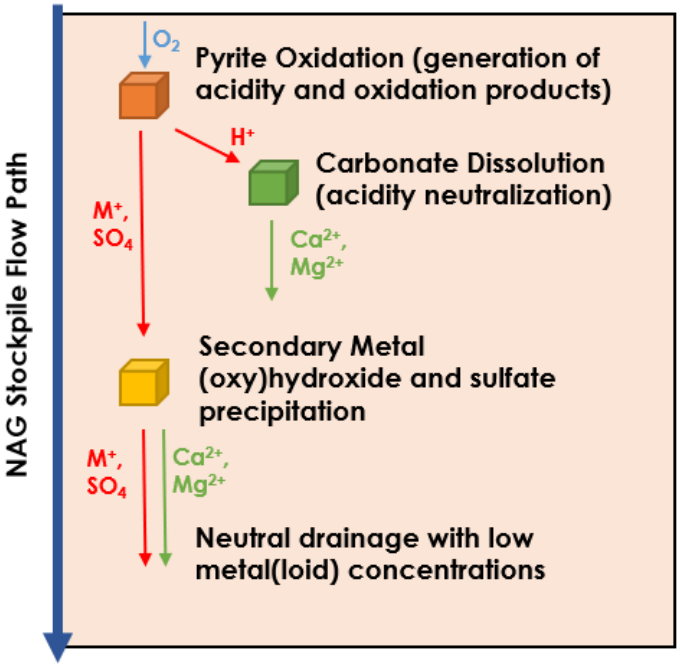

Figure 2.3: Geochemical conceptual model for Tenas NAG mine rock flow path.

Parameters that were elevated above typical crustal concentrations within the Project Area were: arsenic, phosphorus, sulfur, and selenium. Although elevated solid-phase concentrations do not necessarily imply that these species will be mobilized and result in elevated concentrations in contact water, solid-phase metals analysis was completed to flag potential contaminants of concern to evaluate in further geochemical testing.

Current geochemical characterization recommended the use of a neutralization potential ratio (NPR) > 1.60 to classify mine rock as NAG (where, NPR = neutralization potential / acid potential) during verification testing completed during the Operations phase of the Project. For planning and the EAC submission, an NPR cutoff of 2.0 was used to classify mine rock as NAG or PAG, with values > 2.0 considered NAG. This is based on a strong correlation between NP_{XRD} and modified NP following correction for iron carbonates and was developed using calcium and magnesium molar ratios in humidity cell tests (HCTs; SRK, 2022b).

Dolomite-ankerite and calcite are the most abundant carbonate minerals with lesser amounts of siderite in NAG mine rock while PAG mine rock has a higher siderite content. Dolomite-ankerite content ranged from 0.3 to 23.8 wt.% (median = 14.0 wt.%), while calcite ranged from below detection (BD) to 4.4 wt.% (median = 1.4 wt.%). Siderite content ranged from 0.2 to 12.6 wt.% (median = 2.0 wt.%). It is worth noting that siderite does not provide net neutralization to acidity generated from sulfide oxidation. This is because Fe(II) released from siderite dissolution typically oxidizes to Fe(III) which precipitates Fe(III)

hydroxide phases, releasing acidity. Therefore, the bulk of acidity neutralization in the NAG mine rock will come from the dissolution of calcite and dolomite. The primary sulfide mineral in the PAG mine rock is pyrite, which ranges from 0.3 to 2.5 wt.% (median = 0.8 wt.%).

3 DESCRIPTION OF MODELLING PROCESSES

To estimate seepage quantity and quality for the backfilled NAG mine rock in the Open Pit, Okane used the following numerical models and modelling process.

1) *One-Dimensional (1D) Soil-Plant-Atmosphere (SPA) Models* using components of the GeoStudio FLOW (Bentley Systems, 2022) modelling suite (namely, SEEP/W and TEMP/W) to simulate the NP rate.

2) *Two-Dimensional (2D) Oxidation Model* using the GeoStudio FLOW suite, including SEEP/W, TEMP/W, CTRAW/W, AIR/W, and the Gas Consumption and Exothermic Reactions Add-In Module to evaluate the size and development of suboxic conditions.

3) *Three-Dimensional (3D) GoldSim Oxidation, Wetting-Up and Draindown Model* to determine a range for potential seepage and oxygen consumption based on hundreds of realizations of the model, using the GoldSim Monte-Carlo formulation (GoldSim, 2021).

4) The *Geochemical Model* using a combination of both a *mechanistic reactive transport model* and a *scale-up geochemical model* to evaluate the evolution of water quality moving through the overburden cover and into the backfilled NAG mine rock.

The source terms from the geochemical model will be provided to SRK to be used in the site-wide water quality model to evaluate the potential effects of key mine facilities on the receiving environment. The following sections describe the numerical models in more detail.

3.1 1D Soil-Plant-Atmosphere Model with GeoStudio SEEP/W and TEMP/W

In combination, SEEP/W and TEMP/W are a 2D finite element model (which can also perform 1D simulations) that predict suction in the material profile in response to climatic forcing (such as evaporation) and lower boundary conditions (such as a water table). A key feature of the software is the ability of the model to predict actual evapotranspiration (AET) based on potential evaporation (PE) and predicted suction, as opposed to the user being required to input these surface flux boundary conditions. The AET rate from the surface material is below the potential rate during prolonged dry periods because the suction, or negative pore water pressure, in the material profile increases as the surface desiccates. In addition, SEEP/W and TEMP/W together form a fully coupled (through the vapour pressure term) heat and mass transfer model, which can predict water vapour movement and the influence of freeze/thaw on hydraulic conditions through reductions in the hydraulic conductivity. The 1D SPA models provide runoff and NP estimates, which are used as inputs in the 2D Oxidation and 3D GoldSim Oxidation, Wetting-Up, and Draindown models.

3.2 2D Oxidation Models

The 2D oxidation modelling was completed using the GeoStudio FLOW suite (SEEP/W, TEMP/W, CTRAN/W, and AIR/W) and the Gas Consumption and Exothermic Reaction Add-In to evaluate the size and development of suboxic zones within the NAG backfill. The models will account for annual material placement and provide estimates of the timing and depth to the suboxic zones, which are used in the 3D GoldSim model, as well as an estimate of cumulative oxygen (O_2) consumption with time, which is used to calibrate and validate the 3D GoldSim results.

3.3 3D GoldSim Oxidation, Wetting-Up and Draindown Model

The 3D model is a wetting-up and drain-down model developed by Okane in GoldSim to simulate the water movement in mine rock based on climate data and material properties. In the model, gravity-driven water flow depends on the NP rate and hydraulic conductivity. The hydraulic conductivity of each layer of mine rock is calculated based on the following formula with measured material properties:

$$k(h) = k_s S_e^l \left[1 - \left(S_e^{\frac{1}{m}}\right)^m\right]^2 \quad (1)$$

where S_e is the effective saturation, k_s is the saturated hydraulic conductivity (LT^{-1}), n and m are van Genuchten's equation parameters, and l is the pore-connectivity parameter. The effective saturation, S_e, within the layer is defined as:

$$S_e = \frac{\theta_w - \theta_{wr}}{\theta_s - \theta_{wr}} \quad (2)$$

where θ_w is the volumetric water content of the layer, θ_{wr} is the residual volumetric water content (L^3/L^3), and θ_s is the saturated volumetric water content (L^3/L^3). The van Genuchten equation parameter m is defined as a function of n as:

$$m = 1 - \frac{1}{n} \quad (3)$$

In the modelling process, hydraulic conductivity is calculated based on the water content of each layer of mine rock. This parameter is then used to calculate the flow rate of water between layers of mine rock. The change in water content due to the placement of new mine rock can also be simulated as part of the hydrogeology model. The Monte-Carlo formulation is used to vary the material properties for each lift of material within an anticipated range to produce a more realistic estimate of overall backfill performance.

The 3D models were extended an additional 50 years to 2150 using stochastic net percolation inputs based on the 1D water balance to ensure that steady state seepage was reached.

3.4 Geochemical Model

The evolution of water quality in the backfilled NAG mine rock was evaluated using a combination of both a mechanistic reactive transport model and a scale-up geochemical model.

The *Mechanistic Reactive Transport Model* was constructed with PHREEQC v.3 (Parkhurst and Appelo, 2013) and accounts for geochemical characteristics such as mineralogy, reaction kinetics, transport time, and oxygen conditions of the mine rock. This model incorporates key reactive minerals including sulfides and carbonates, chronology of the NAG mine rock placement, and cover system placement and source control implementation leading to suboxic zone development.

The *Scale-up Geochemical Model* was completed to estimate parameters that were not modelled using the Mechanistic Geochemical Model, and generally consist of parameters not directly influenced by sulfide oxidation or carbonate mineral dissolution. Parameter concentrations were calculated based on field barrel leachate quality and scaled-up based on the physicochemical differences between the smaller scale test conditions and expected field conditions of the NAG backfill.

3.5 Model Inputs

3.5.1 Base Case Geometry

The in-pit NAG backfill will be constructed as 120 m wide by 36 m high cells, with a 3 m cover of compacted overburden on the slope of the cell and 1 m of compacted overburden on the plateau of each cell. The cells will be built starting with the face of the slope as a 4 m by 50 m lift / road (1 in Figure 3.1). The overburden and NAG mine rock will be end dumped and compacted in 1.33 m lifts. The second lift will be a 4 m by 39 m lift (2 in Figure 3.1) on top of the first lift, followed by a third lift of 4 m by 28 m (3 in Figure 3.1). The remaining space within the cell will be end dumped as a 12 m high standard dump (4 in Figure 3.1). This process is planned to occur three times per cell, resulting in a 35 m high cell. The last step of each cell is the addition of a 1 m compacted overburden layer, completing the 36 m high cell.

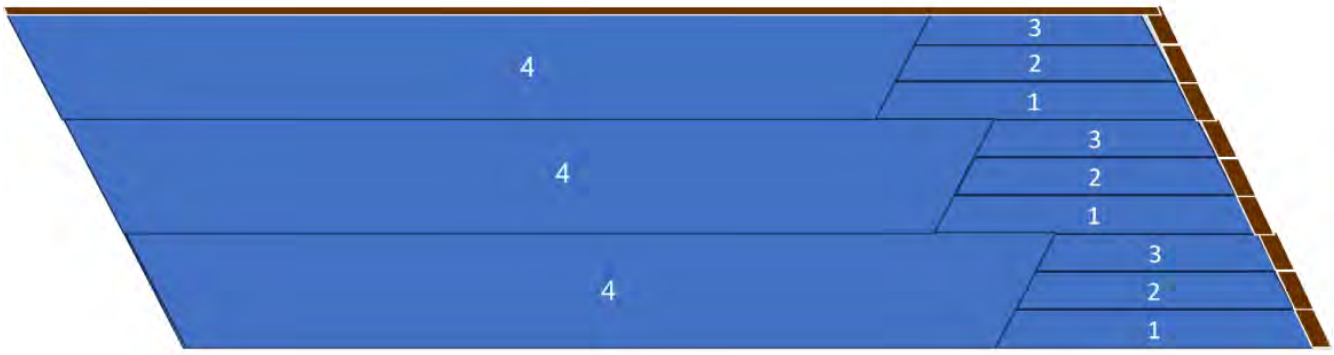

Figure 3.1: Building plan for the cells within the backfilled open pit NAG mine rock landform.

Cells will be stacked and reach an approximate height of three 36 m cells to complete the backfill within the Open Pit, as the bottom and top cells are anticipated to be half height, as shown in Figure 3.2, due to the pit bottom shape and final reclamation goals.

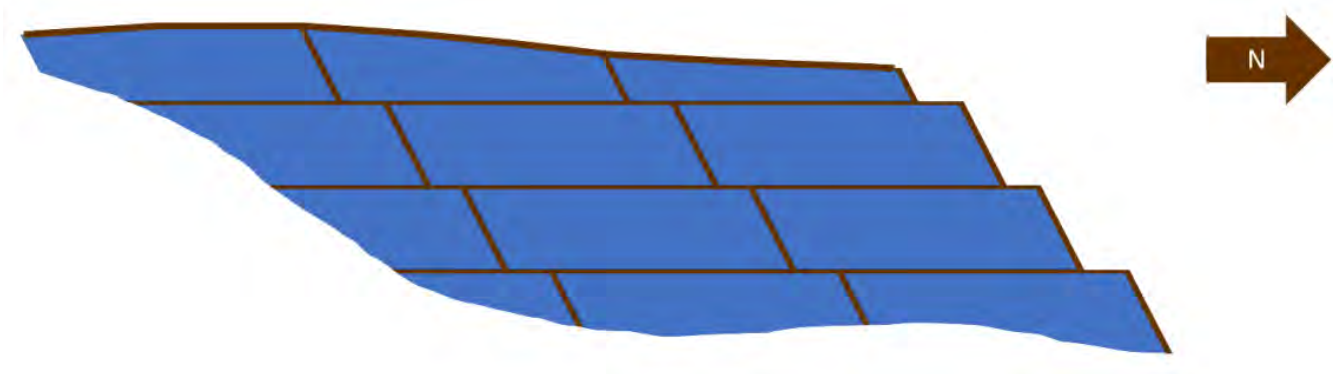

Figure 3.2: Encapsulation plan for NAG in-pit mine rock.

The final cover system on the landform will be 3 m of overburden overlain by approximately 0.3 m of surface soils (topsoil). The 1D models were constructed as 35 m of mine rock with the final cover system at the surface. These models were used to investigate the different material combinations.

A cross-section through the NAG backfill was modelled in 2D to determine the development and extent of the suboxic zone within the backfill. Figure 3.3 shows the approximate location of the cross section while Figure 3.4 shows the 2D geometry that was modelled.

An additional scenario that did not include the internal overburden layers was also modelled. This scenario assumed that the Open Pit would be backfilled following the same procedure as outlined above, but the entire 36 m cell would be composed of mine rock, with only the final cover system being composed of overburden.

Figure 3.3: Plan view of the backfill open pit NAG mine rock showing the strips and approximate location of the projected cross section.

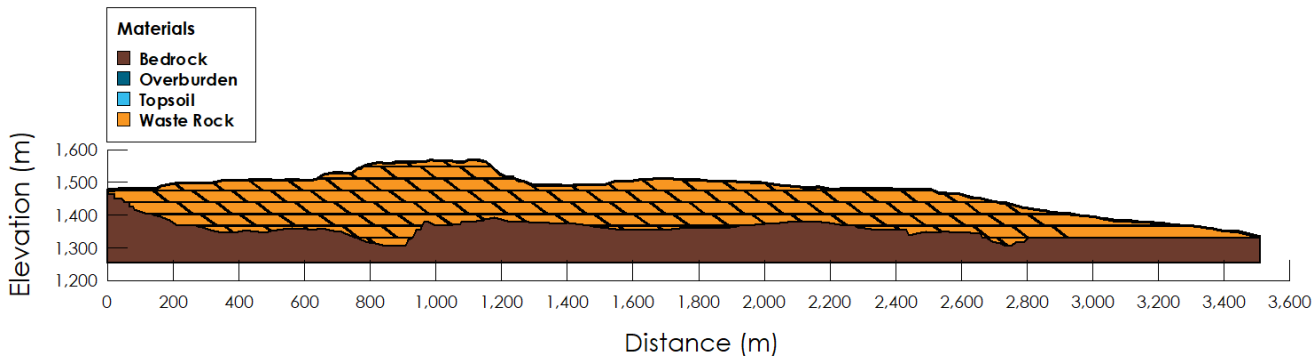

Figure 3.4: Geometry of the project 2D cross section. It should be noted that bedrock refers to bedrock of open pit, waste rock is the NAG mine rock and topsoil includes surface soils.

Within the 3D GoldSim model, the backfilled NAG mine rock was simulated by subdividing its area into 23 main strips, with each strip representing areas with similar timing of cover placement (Figure 3.3). The construction schedule for each strip was assumed based on the filling volumes and timing provided by Telkwa. The following assumptions were made regarding the placement of NAG mine rock for the GoldSim simulations:

- Construction of the NAG backfill is strip dependent, but in general, begins in Year 6 for the main strips and continues until the completion of the Operation phase in Year 21;
- Cover system placement is strip dependent and will be assumed to occur over one year (*e.g.*, cover placement that occurred in Year 8 will be assumed to occur at a uniform rate from January 1 to December 31 of Year 8). Cover system placement is assumed to occur in the year following completion of each strip due to model limitations; and
- Daily NP rate inputs will be derived separately from the 1D GeoStudio model results. In general, daily stochastic inputs will be setup for each day of the year based on the results of the GeoStudio models.

The assumed height of NAG mine rock and overburden in each strip with time, based on the volume of material placed and the surface area of the strip is shown in Figure 3.5. The surface area, total NAG mine rock and overburden volumes, and timing of cover system placement are listed in Table 3.1. For the no internal layers scenario, the internal layer volume was assumed to be NAG mine rock rather than overburden.

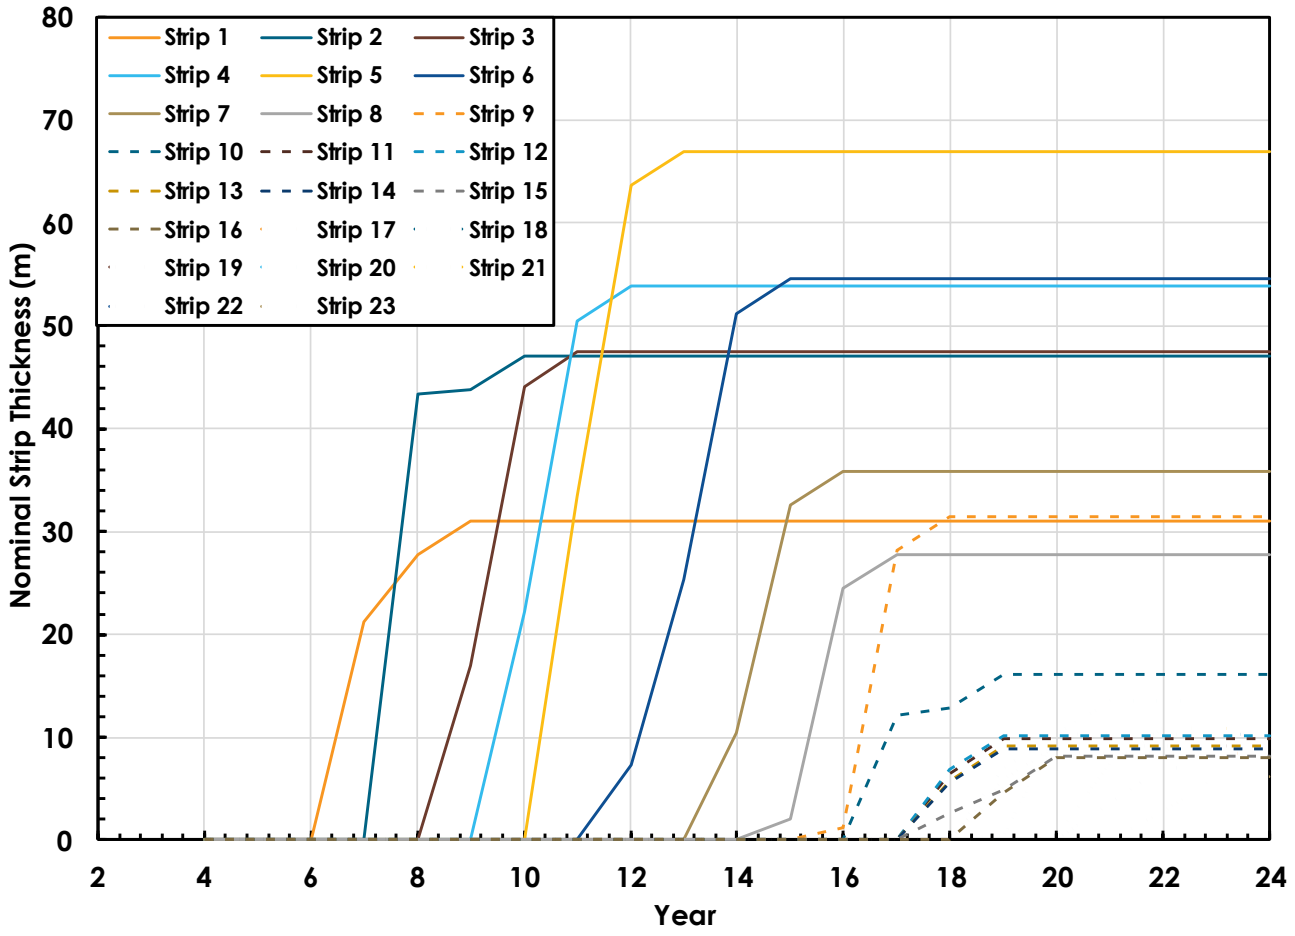

Figure 3.5: Evolution of nominal strip thickness within the GoldSim model for each strip.

Table 3.1: Surface area, volume, and nominal thickness of each strip, along with year of cover system placement.

Strip	Strip Surface Area (m^2)	Mine Rock Volume (m^3)	Internal Layers Overburden Volume (m^3)	Cover System Overburden Volume (m^3)	Total Strip Volume[1] (m^3)	Nominal Thickness (m)	Year of Cover Placement

1 - Includes total NAG mine rock and overburden volumes.

3.5.2 Material Properties

The hydraulic properties or functions required for modelling of overburden and NAG mine rock material are as follows:

- Water retention curve (WRC – volumetric water content versus matric suction): a continuous function relating energy and the state of water, and hence describes the water content of a material as a function of the soil suction, or negative pore-water pressure. It is central to the design of an unsaturated soil system.

- Hydraulic conductivity function (k-function – hydraulic conductivity versus matric suction): a measure of the ability of a soil or rock material to transmit water and is a maximum for saturated soil or rock materials. The saturated hydraulic conductivity (k_{sat}) and unsaturated hydraulic conductivity function are key input parameters to numerical models analyzing hydraulic performance.

For the best results, WRC and k_{sat} should be measured in the laboratory and field for each material of interest. In this case, only particle size distribution (PSD) data was available for the overburden material and no information was available for the NAG mine rock. Two PSDs for the overburden material were used as representative samples for well-graded (sample# 35087) and poorly-graded (sample# 35094) till found in the SRK 2019 field investigations (Figure 2.2).

For the overburden material the WRC (Figure 3.6) and k-function (Figure 3.7) were estimated from the PSD (both well-graded and poorly-graded) using the Fredlund and Xing (1994) pedotransfer functions in SVSOILS™ Software (Plaxis, 2022). The k_{sat} was estimated using Kozeny (1962) with PSD data as the input.

As no lab or field information was available for the NAG mine rock, three proxy materials (mudstone, siltstone, and sandstone) were provided by Okane based on field testing completed at several mine sites. A well-graded mixed material based on core logs consisting of 35% mudstone, 60% siltstone, and 5% sandstone (D. Farmer, 2024, pers. comm.) was also estimated. The WRC and k-functions for the mine rock proxy materials are found in Figure 3.6 and Figure 3.7, respectively.

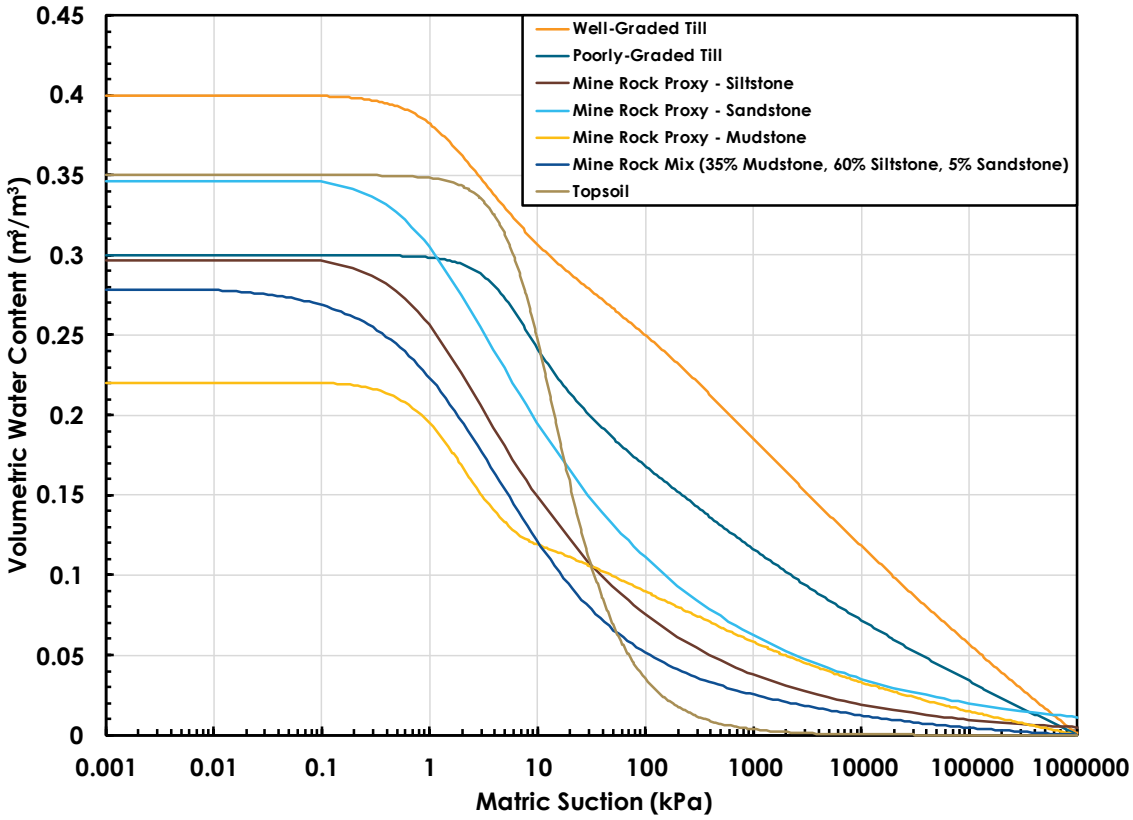

Figure 3.6: Estimated overburden (till) and proxy mine rock water retention curves.

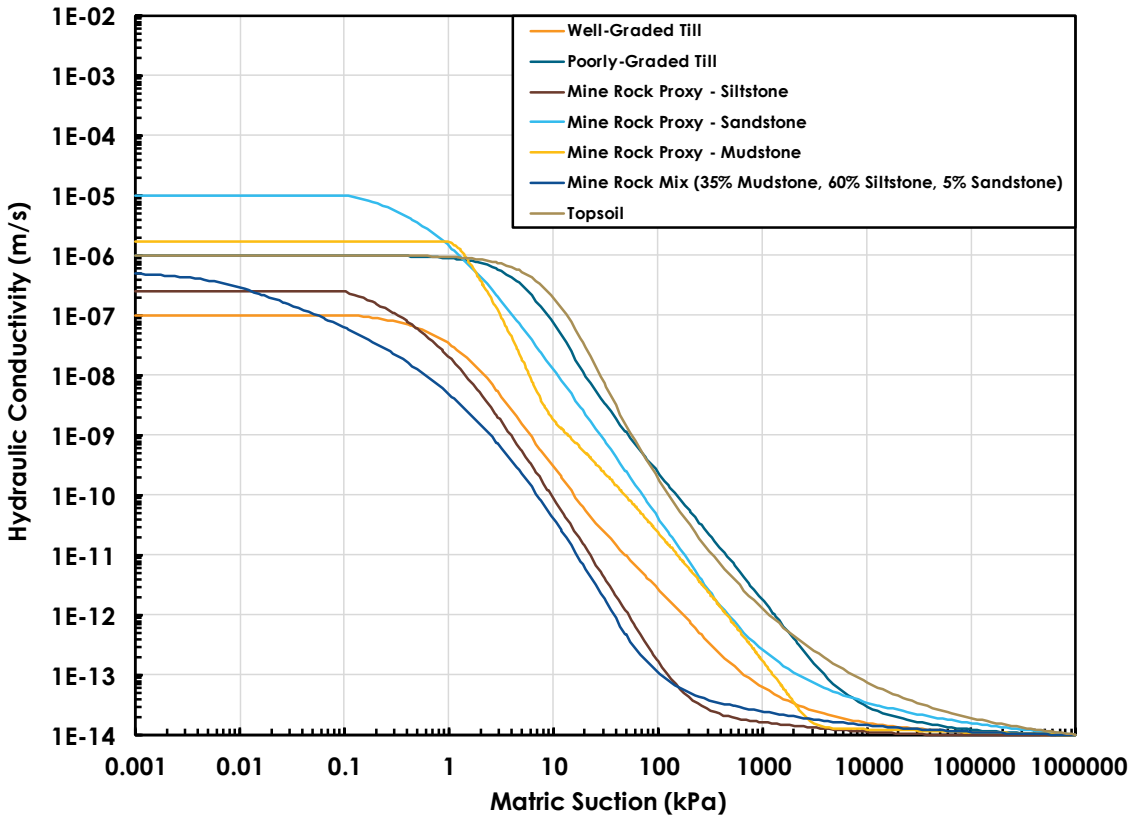

Figure 3.7: Estimated overburden (till) and proxy mine rock k-functions.

3.5.3 Climate Model Inputs

SRK (2022c) developed a project-specific synthetic historical climate database based on transposing regional datasets to the site and adjusting for orographic effects. The historical dataset spans 77 years from 1943 to 2020 and is summarized in Table 3.2.

SRK (2022c) also completed a climate change assessment for the project using the fifth version of the Coupled Model Intercomparison Project (CMIP5) and Representative Concentration Pathway (RCP) 4.5 of the Intergovernmental Panel on Climate Change (IPCC) fifth Assessment Report (AR5) (IPCC, 2014). Monthly rates of changes relative to baseline conditions (1981-2010) were calculated for temperature and precipitation based on the median values of an ensemble of 29 CMIP5 models. Projected climate change effects were evaluated for three consecutive 30-year forecast periods, defined as follows:

- Baseline period from 1981 to 2010 (CMIP5), centred on 1995;
- First forecast period from 2011 to 2040 (CMIP5), centred on 2025;
- Second forecast period from 2041 to 2070 (CMIP5), centred on 2055; and

- Third forecast period from 2071 to 2100 (CMIP5), centred on 2085.

Monthly changes relative to monthly baseline data for RCP4.5 are shown in Table 3.3 for temperature and Table 3.4 for precipitation. A long-term daily dataset (SRK, 2023a) was developed by applying the monthly changes to the average monthly values from the baseline period.

This climate change dataset was used directly as the upper boundary condition in the 1D SPA modelling through the Land-Climate Interaction (LCI) and Surface Energy Balance (SEB) boundary conditions to develop the surface water and energy balance, which was used as the upper boundary conditions in the 2D and 3D models.

Table 3.2 Monthly summary of historical climate database.

Month	Air Temperature (°C)		Precipitation[1] (mm)				Solar Radiation (W/m²)	Relative Humidity (%)	Lake Evaporation (mm)	Wind Speed (m/s)

3.5.4 Vegetation Model Inputs

Vegetation model inputs were based on the SBS bio-geoclimatic zone. Prior to reclamation, no vegetation was assumed. Once areas are reclaimed, vegetation was simulated to re-establish and grow.

To simulate the vegetation re-establishment the following assumptions were made:

- The year after cover system placement, grasses and shrubs are assumed to establish and grow.
- Grasses and shrubs are assumed to be the predominant vegetation for the first five years following cover system placement.
- Forest species are assumed to be the predominant vegetation after the grasses.

3.5.4.1 Rooting Depth and Distribution

The rooting depth and distribution was described by the work of Jackson *et al.* (1996) using the equation:

$$Y = 1 - \beta d \qquad (4)$$

where Y is the cumulative root fraction (a proportion between 0 and 1) from the soil surface to depth d (cm), and β is the fitted 'extinction coefficient', which Jackson *et al.* (1996) estimates as 0.943 for both grassland and boreal forest biomes. Hence, the same rooting depth and distribution (Figure 3.8) were used to represent both grasses and forest growth.

The maximum rooting depth is approximately 1.2 m, with 95% in the top 0.5 m of the cover system. This is like the root characteristics described in Klinka *et al.* (2000) for tree species in the region.

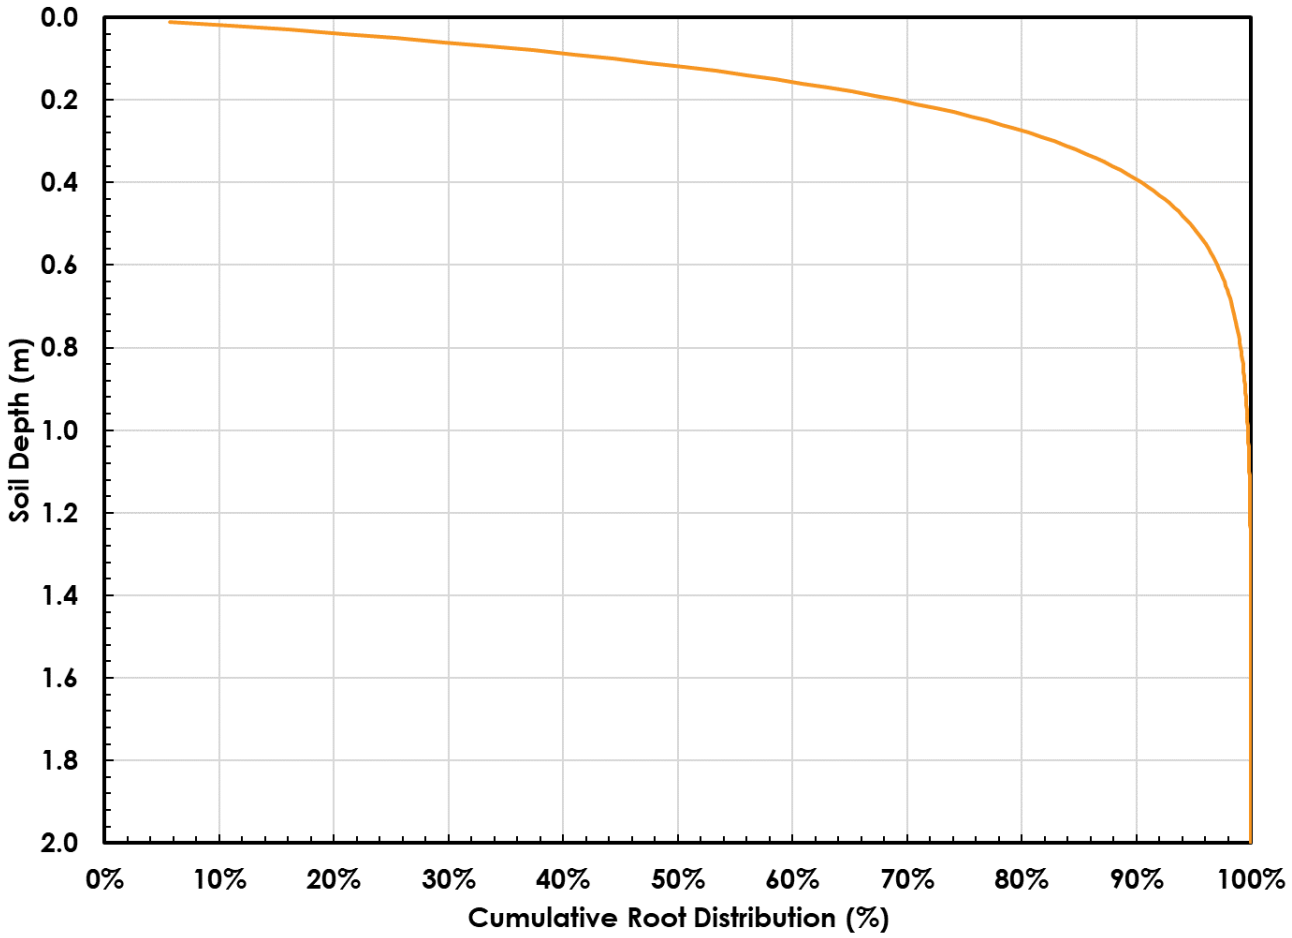

Figure 3.8: Estimated rooting depth and distribution for grasses and forest growth at Tenas Project.

3.5.4.2 Leaf Area Index and Percent Ground Cover

The Leaf Area Index (LAI) for grasses is estimated to be 1.7 with a percent ground cover of 70%. Once forest and understory species establish, LAI is estimated to increase to 2.3 with a percent ground cover of 85%. During the first seven years of vegetation, the LAI was increased annual by 0.3, starting at an LAI of 0.3, to gradually reach the mature forest vegetation LAI of 2.3.

3.5.4.3 Plant Water Limiting Function

Lack of available water and/or high evaporative demands will cause most plants to biologically react by closing stoma, reducing transpiration, and reducing metabolic reactions (Saxton, 1982). Under continued and increasing stress, the plant will reach its permanent wilting point (PWP), at which point transpiration is estimated to cease. The plant water limiting function (PWLF) defines the reduction in transpiration due to increased soil suction conditions. In general, the PWLF is defined to start to reduce at 10 kPa and stop transpiration entirely at a PWP of 1,500 kPa. This function was used to simulate grasses

growing on the cover system. Lopushinsky and Klock (1974) measured the PWLF for conifer species, which produced the PWLF (Figure 3.9). This PWLF was used to simulate forest growth.

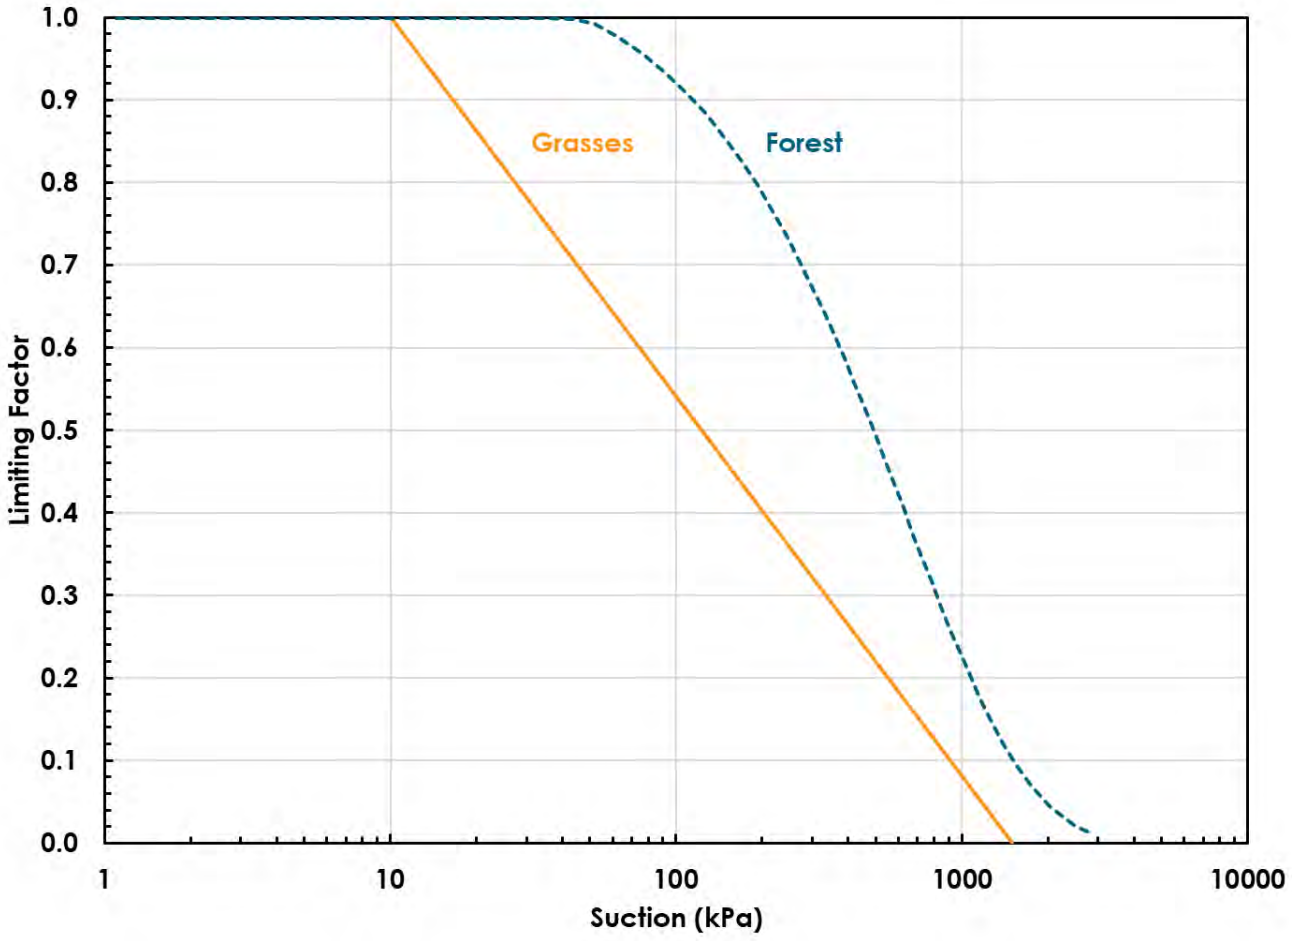

Figure 3.9: PWLFs estimated to simulate grasses and forest growth.

3.5.4.4 Growing Season

To define the growing season, the following assumptions were made:

- The growing season starts once the snowpack is completely melted and mean daily air temperature is above 5°C.
- The growing season ends once the minimum temperature after September 1 drops below 0°C.

3.5.5 Lower Boundary Conditions

The lower boundary condition was assumed to be a unit hydraulic gradient for the 1D simulations. This boundary condition assumes that the movement of water at the depth of the lower boundary is no longer influenced by atmospheric forces and is moving downwards only due to gravity.

3.5.5.1 Initial Conditions

The initial conditions for the 1D SPA model were obtained by running the models twice, using the final conditions of the first simulation as the initial conditions of the second simulation. This is done to remove the subjectivity of the ascribed initial conditions from the model results. The initial conditions of the 2D and 3D models were based on the results of the 1D SPA model.

3.5.6 Geochemical Model

Source terms for the NAG pit backfill were developed using a geochemical model based on the facility specific conceptual model. Source terms were modelled using both mechanistic reactive transport models and geochemical scale-up models. Source terms were developed for three scenarios; two cover system scenarios, a poorly graded till and sandstone mine rock scenario and a well graded till and blended mine rock (60% siltstone, 35% mudstone and 5% sandstone) with internal layers scenario and a third well graded till and blended mine rock (60% siltstone, 35% mudstone and 5% sandstone) without internal layers scenario. Source terms for the NAG pit backfill can be found in Appendix A.

3.5.6.1 Geochemical Model Methodology

Reactive transport models utilized the geochemical code PHREEQC to apply mineralogical kinetics that applicable to NAG mine rock from the Project. The purpose of the reactive transport model was to incorporate mineral kinetics, water flow, and oxygen availability to simulate the evolution of sulfide oxidation rates, metal leaching, and carbonate dissolution simultaneously over a long-term timeframe. Reaction kinetics were calibrated to NAG mine rock barrel tests that are ongoing at the Tenas site (SRK, 2022b). The geochemical scale-up model utilized NAG barrel tests from the Tenas project to calculate loading rates of parameters that are not strongly influenced by sulfide oxidation and carbonate dissolution. Source terms of these parameters were scaled up to conditions representative of the NAG backfill.

Parameters that were modelled via the reactive transport model included pH, alkalinity, SO_4, Al, Ag, As, Ca, Co, Cr, Cd, Cu, Fe, Hg, Mg, Mn, Na, Ni, Pb, Si, Sr, Sn, U, V, Zn, NO_3, NH_3, and NO_2. The mechanistic reactive transport model was developed in two phases:

- *Phase 1* – The reactive transport model was developed and calibrated using mineralogical data and barrel test leachate data for representative NAG mine rock.

- *Phase 2* – The calibrated reactive transport model for the barrel test was scaled to field conditions by adjusting for the differences in hydrology, temperature, and mass of the reactive particle size fraction (< 6.35 mm in the barrel tests) between the barrel tests and full-scale conditions.

Parameters not incorporated into the reactive transport model were estimated using a geochemical scale-up model. This model was developed by scaling up barrel test production rates by using facility- and site-specific adjustment factors to obtain representative weathering rates. Parameters incorporated in this model included Ba, B, Be, Li, K, P, Si, Sr, Ti, and Zr. Adjustment to full scale conditions was completed by applying scaling factors for reactive particle size, and water contact.

3.5.6.2 Model Development

Reactive transport models were developed for the B1 and B2 barrel tests combined and for the B7 barrel test. The B1 and B2 were combined as these barrels were constructed using the same NAG mine rock samples while the B7 barrel test used different NAG mine rock samples.

Mineralogical analyses for several samples used in the barrel tests reported a single mass for the dolomite-ankerite phase while other samples reported a unique mass for both dolomite and ankerite. Therefore, for modelling purposes it was assumed that if dolomite-ankerite was reported, 50% of this mass was dolomite and the other 50% was ankerite. The reactive mineralogy modelled in the NAG barrel tests is summarized in Table 3.5.

Table 3.5: Summary of reactive minerology in NAG mine rock barrel tests (from SRK, 2022b).

Mineral Name	Unit	B1 and B2	B7	Median NAG Mine Rock
Calcite	wt.%	2.3	0.5	1.4
Siderite	wt.%	7.3	7.8	2.0
Dolomite	wt.%	8.9	8.0	6.9
Ankerite	wt.%	7.9	3.4	0.4
Pyrite	wt.%	4.6	2.0	0.8

Metal leaching was assumed to be predominantly associated with pyrite oxidation. Therefore, metal(loid)s were added to the pyrite mineral phase in PHREEQC based on the molar ratio of respective metals to SO_4 in barrel test leachates (Table 3.6). Divalent cationic metals were assumed to substitute for Fe, while anionic metals were assumed to substitute for S in the pyrite structure. This enabled the release of metals commonly associated with pyrite to be closely coupled to the kinetics of pyrite dissolution in the model.

Table 3.6: Molar composition of pyrite phase used in the reactive transport model.

Parameter	Molar Composition
Fe	0.9999384
Ni	0.0000177
Co	0.0000051
Cu	0.0000044
Pb	0.0000014
Mn	0.000022
Zn	0.0000097
Se	0.000045
As	0.0000013
S	1.99995

Kinetic rate equations were added to the reactive transport model based on published rate law equations and reaction rate coefficients for both the oxidation of sulfide minerals and the dissolution of carbonate phases (Table 3.7). Due to limited kinetic and thermodynamic data associated with ankerite in literature it was assumed that ankerite had the same thermodynamic and kinetic properties as dolomite in the model.

The hydraulic regime of the reactive transport model of the barrel test followed leachate collection events when leachate volumes were measured. Material properties for the reactive particle size fraction (< 6.35 mm) from the water balance modelling were used and assumed a porosity of 0.35 and degree of saturation of 50%, corresponding to a volumetric water content of 0.175 m^3/m^3 in the barrels.

Table 3.7: Kinetic rate equations for minerals included in the reactive transport model.

Mineral	Rate Equation	Rate Constant, k (mol m^{-2} s^{-1})	Effective Rate Constant, k_{eff} (mol m^{-3} s^{-1})	Reference
Pyrite	$Pyrite\ Rate = k\ x \left(\frac{A}{V}\right)\ x\ [H^+]^{-0.11}\ x\ [O_2]^{0.5}\ x\ \left(\frac{m}{m_0}\right)^{\frac{2}{3}}$	1.1 x 10^{-10}	-	Williamson and Rimstidt, 1994 Xu et al., 1998
Calcite	$Calcite\ Rate = (k_1\ x\ [H^+] + k_2\ x\ [H_2CO_3])\ x \left(\frac{A}{V}\right)\ x \left(\frac{m}{m_0}\right)^{\frac{2}{3}}$	$k_1 = 10^{-0.05}$ $k_2 = 10^{-0.05}$	-	Chou et al., 1989
Dolomite	$Dolomite\ Rate = k\ x \left(\frac{A}{V}\right)\ x\ [H^+]^{0.5}\ x \left(\frac{m}{m_0}\right)^{\frac{2}{3}}$	$10^{-2.59}$	-	Chou et al., 1989
Ankerite	$Ankerite\ Rate = k\ x \left(\frac{A}{V}\right)\ x\ [H^+]^{0.5}\ x \left(\frac{m}{m_0}\right)^{\frac{2}{3}}$	$10^{-2.59}$	-	*
Siderite	$Siderite\ Rate = k_{eff}\ x \left(\frac{m}{m_0}\right)^{\frac{2}{3}}$	-	$10^{-9.52}$	Dresel, 1989

*Ankerite kinetic characteristics were assumed to be similar to dolomite.

3.5.6.3 Calibration

The reactive transport model was calibrated by adjusting mineral-specific surface areas or effective rate coefficients (Table 3.8) such that modelled barrel test results were comparable to the median leachate concentration of the barrel tests. A separate model was calibrated for the B1 and B2 barrel tests together and another model was calibrated to the B7 barrel test.

Substantial cation exchange between Na, Ca, and Mg was observed in the barrel tests. Carbonate dissolution releases Ca^{2+} and Mg^{2+} that subsequently exchange for Na^{+} from surface sites of the host rock (likely associated with clay minerals). The resulting leachate from the barrel tests is enriched in Na concentrations. In order to calibrate the reaction rate for carbonate dissolution, Ca and Mg concentrations needed to be back calculated from the Na concentrations in the leachate. It was assumed that all Na was sourced from cation exchange with Ca and Mg. The ratio of Ca/Na exchanged compared to Mg/Na exchanged was calculated based on the ratio of ion exchange coefficients of Ca-Na and Mg-Na exchange pairs (Bruggenwert and Kamphorst, 1982).

Table 3.8: Calibrated values of kinetic rate equation parameters.

Mineral	Calibrated Surface Area/Volume (dm^{-1})		Calibrated Effective Rate Coefficient (mol m^{-3} s^{-1})	
	B1 and B2	B7	B1 and B2	B7
Pyrite	-	-	$10^{-8.585}$	$10^{-8.72}$
Calcite	0.01	0.009	-	-
Dolomite	0.02	0.007	-	-
Ankerite	0.01	0.007	-	-
Siderite	-	-	$10^{-9.523}$	$10^{-9.523}$

Following the calibration of the barrel test scale reactive transport model, there was good agreement between modelled parameter concentrations and measured leachate chemistry from the mine rock barrel tests (Figure 3.10). The average of the calibrated factors for the B1/B2 and B7 models were used in the full-scale reactive transport model.

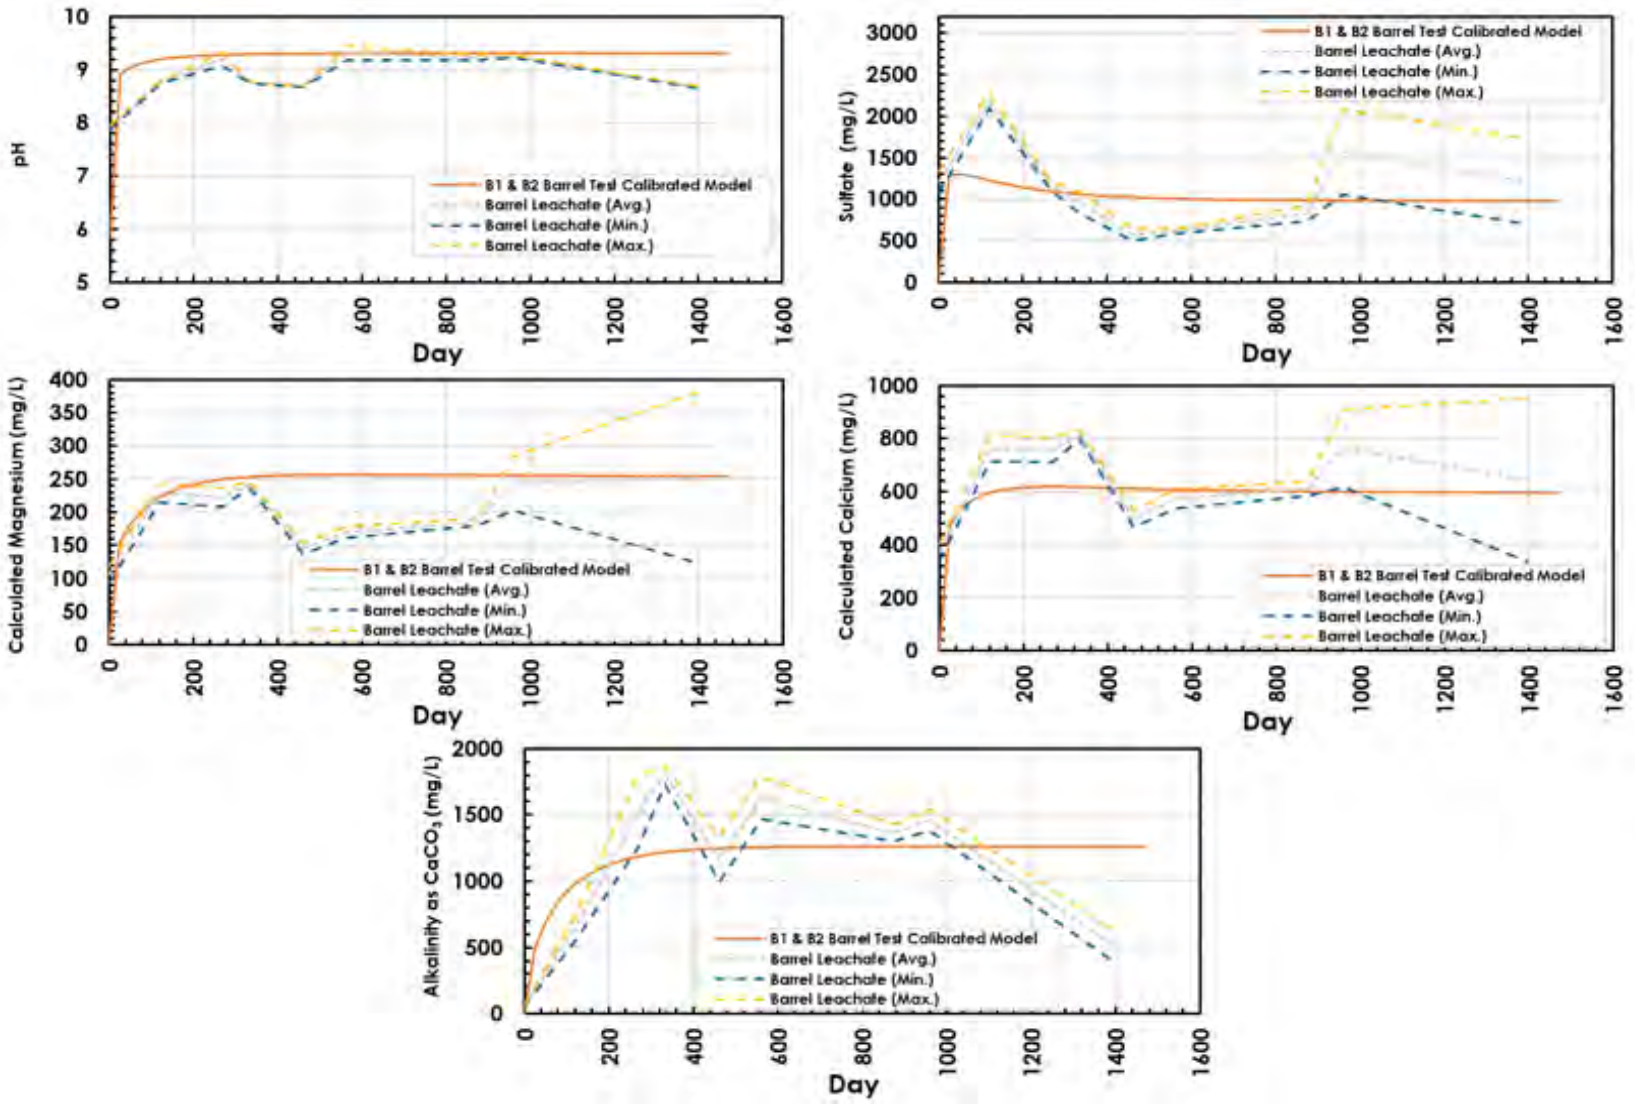

Figure 3.10: Parameter concentrations for the calibrated model versus minimum, maximum, and average B1 and B2 leachate concentrations.

3.5.6.4 Model Scale-Up

Once the geochemical model was calibrated to the field barrel tests, the reactive transport model was scaled up using the nominal height of respective strips (Table 3.1) within the NAG backfill with the final output being stockpile drainage chemistry. GeoStudio oxidation modelling provided stockpile temperature and thickness of both oxic reactive and suboxic non-reactive material. Hydraulic information such as the timing and amount of seepage for the full-scale model was provided by the GoldSim hydrological and seepage models for bare surface and covered conditions.

Temperature Adjustments

The effects of temperature on the literature values for the rate constant of each mineral modelled in the NAG backfill was adjusted using the Arrhenius equation (Equation 4; Gautelier et al., 1999). The temperature adjustment was performed on barrel tests that used an average annual air temperature of 4.9°C. The average internal NAG backfill temperature was estimated to be approximately 3°C based on the GeoStudio oxidation model, and this temperature was used to scale the reaction rates.

$$k_T = k_{25°C}\, x\, A^{\left(\frac{-Ea}{R\Delta T}\right)} \quad (5)$$

Where:

- k_T is the rate constant at temperature, T;
- $k_{25°C}$ is the rate constant at 25°C;
- A is the pre-exponential factor (2.718 s^{-1});
- E_a is the activation energy (kJ);
- R is the molar gas constant (8.314 J K^{-1} mol^{-1}); and
- ΔT is the temperature difference $\left(\frac{1}{T\ (K)} - \frac{1}{298.15\ K}\right)$

The activation energies used for the temperature correction of mineral reaction rates are summarized in Table 3.9. Only pyrite, calcite, and dolomite were adjusted for temperature, while reactivity of siderite was maintained under standard conditions due to a lack of information.

Table 3.9: Activation energies for minerals included in the reactive transport model.

Mineral	Activation Energy (kJ)	Reference
Pyrite	70	Lowson, 1982
Calcite	20.9	Sajwan and Evangelou, 1991
Dolomite	36.1	Herman and White, 1985
Siderite	-	-

3.5.6.5 Reactive Transport Model of the NAG Backfill

Infiltrating Water Chemistry

The chemical signature of the infiltrating water (or net percolation) was assumed to be equal to the water chemistry of a site-specific overburden barrel test because of the use of overburden in the cover system (Table 3.10). Initial NAG backfill porewater was assumed to be similar to the initial water chemistry sampled from the NAG barrel tests. An average from the B1/B2 and B7 tests was used in the full-scale model.

Table 3.10: Reactive transport model infiltrating water and initial NAG backfill porewater composition.

Parameter	Unit	Infiltrating Water Composition	Initial Porewater Composition
pH	-	8.2	7.9
Sulfate (Dissolved)	mg/L	118	1,205
Alkalinity (Total as $CaCO_3$)	mg/L	0.1	106
Chloride (Dissolved)	mg/L	0.25	3.83
Fluoride (Dissolved)	mg/L	0.13	-
Arsenic (Dissolved)	mg/L	0.00078	0.00012
Calcium (Dissolved)	mg/L	45.0	372
Cobalt (Dissolved)	mg/L	0.00016	0.0057
Copper (Dissolved)	mg/L	0.011	0.001
Iron (Dissolved)	mg/L	0.005	0.01
Lead (Dissolved)	mg/L	0.00014	0.0001
Magnesium (Dissolved)	mg/L	26.0	107
Manganese (Dissolved)	mg/L	0.00052	0.034
Nickel (Dissolved)	mg/L	0.00025	0.0074
Potassium (Dissolved)	mg/L	1.6	3.23
Selenium (Dissolved)	mg/L	0.00058	0.11
Sodium (Dissolved)	mg/L	19	512
Zinc (Dissolved)	mg/L	0.0005	0.0043

Parameter	Unit	Infiltrating Water Composition	Initial Porewater Composition
Nitrate (as N)	mg/L	0.44	56.8
Ammonia (Total)	mg/L	0.0088	7.18
Nitrite (as N)	mg/L	0.0039	1.31

Blasting residues from placed mine rock will leach inorganic nitrogen. Initial source terms of N species (NO_3, NO_2, and NH_4) were determined based on the powder factor (0.5 kg/m^3) and proportion of inorganic N produced based on emulsion and ammonium nitrate fuel oil (ANFO) composition (SRK, 2022a). To calculate the mass of residual N in the NAG backfill, the method by Ferguson and Leask (1988) was used and assumed the following:

- 0.9% of N from ANFO and 5.1% of N from the emulsion as available for leaching (Ferguson and Leask, 1988);
- ANFO is 75% ammonium-nitrate and emulsion comprise the remaining 25%; and
- Leachable inorganic N load from explosives will result in:
    - 87% as NO_3-N;
    - 11% as NH_4-N; and
    - 2% as NO_2-N.

Nitrogen species leaching was incorporated into the reactive transport model by using an assumed volumetric water content, the total volume of material placed, and the mass of residual N to calculate an N concentration leaching from the backfill. This methodology was used so that the hydraulic transport time simulated in the reactive transport model could also be applied to N leaching. Nitrogen species concentrations used in the model are shown in Table 3.10.

Mineralogy

The NAG backfill reactive transport models included both reactive primary minerals and secondary minerals. Reactive primary minerals were limited to pyrite, calcite, dolomite, ankerite, and siderite. Additional minerals (e.g., primary silicates) were identified in the geochemical characterization program (SRK, 2022b); however, these minerals were assumed to be kinetically insignificant during the modelled time scale due to the neutral pH of the NAG backfill.

Elevated concentrations of dissolved metals under neutral pH conditions can result in the precipitation of secondary minerals. Secondary mineral precipitation was incorporated into the final reactive transport and geochemical scale-up model results by completing equilibrium modelling on the source terms. Minerals applied in the equilibrium modelling step were generally consistent with those used in the

SRK (2022a) (Table 3.11). Surface adsorption reactions were not included in the model because it was assumed that adsorption was accounted for in the barrel test leachate chemistry, therefore, the pyrite stoichiometric composition used in the model.

Table 3.11: Model equilibrium phases.

Phase	Empirical Formula	Phase	Empirical Formula
Aluminum Hydroxysulfate	$Al_4(OH)_{10}SO_4$	Ferrihydrite	$Fe(OH)_3$
Amorphous Aluminum Hydroxide	$Al(OH)_3$	Goslarite	$ZnSO_4 \cdot 7H_2O$
Azurite	$Cu_3(CO_3)_2(OH)_2$	Gypsum	$CaSO_4 \cdot 2H_2O$
Barite	$BaSO_4$	Lead Molybdenum Oxide	$PbMoO_4$
Birnessite	$MnO_2 \cdot nH_2O$	Malachite	$Cu_2(CO_3)(OH)_2$
Brochantite	$Cu_4SO_4(OH)_6$	Manganite	$MnO(OH)$
Calcium Molybdenum Oxide	$CaMoO_4$	Melanterite	$FeSO_4 \cdot 7H_2O$
Calcite	$CaCO_3$	Nickel Hydroxide	$Ni(OH)_2$
Chalcanthite	$CuSO_4 \cdot 5H_2O$	Otavite	$CdCO_3$
Carbon Dioxide	$CO_{2(g)}$	Zinc Hydroxide	$Zn(OH)_2$
Copper Hydroxide	$Cu(OH)_2$

Flow Transport

Hydrology is an important component of the NAG reactive transport models. The NAG backfill hydrology used results from the GoldSim hydrological and seepage models (Section 3.3). The NAG backfill reactive transport models were split into 23 cells (Figure 3.3), each having different geometries and mine rock storage capacities (Table 3.1).

Material properties of the bulk mine rock in the NAG backfill were included in the full-scale geochemical model but were adjusted to account for only the reactive fraction of the mine rock (assumed to be the -6.35 mm fraction as used in the barrel tests). Flow of water was assumed to be primarily matrix-dominated. Flow calculations for the model assumed the following material properties for the finer fraction:

- Porosity – The porosity of the finer fraction of the NAG backfill was assumed to be 0.4;
- Degree of saturation – The degree of saturation of the finer fraction in NAG backfill at steady-state was 0.61 based on GoldSim modelling; and
- Proportion of reactive mine rock – The -6.35 mm size fraction typically controls the reactivity of mine rock. The NAG backfill was assumed to composed of 20% -6.35 mm particles based on existing material properties.

The adjusted reactive volumetric water content of the facility was calculated to be 0.049 based on these values and was used to determine cell-specific pore volumes in the reactive transport model.

The volume of water entering of the NAG backfill will change once the mine rock is covered. Additionally, this volume will be different based on the cover system scenario modelled. Three hydrological periods were defined in NAG backfill reactive transport models for each of the modelled scenarios, respectively:

1) *Bare Surface* – This period represented conditions prior to cover system placement on the cell. During this phase, mine rock is exposed to the atmosphere and infiltration rates are 273 mm/year for the poorly graded till and sandstone scenario (Scenario #1) and 143 mm/year for both the well graded till and mixed mine rock scenario (Scenario #2) and the no internal layers scenario (Scenario #3). The duration of the bare surface period is cell-specific and is dependent on the construction and reclamation schedule.

2) Covered Grass NP – This phase represented construction of the closure cover on a cell and occurred for a period of five years as re-vegetation occurs. Once the cover system is placed, both oxygen ingress and NP decrease. Once covered, NP decreases to 197 mm/year in the poorly graded till and sandstone scenario (Scenario #1). Due to differences in runoff between the bare surface and the grass covered surface in the well graded till and mixed mine rock scenarios (Scenarios #2 and #3) NP increased to 148 mm/year.

3) Covered Forest NP – This phase represents maturing of vegetation on the constructed cover system and occurred for the remaining model time following the covered grass NP period. As vegetation matures and shifts to forest dominated NP decreases. Covered forest NP was 124 mm/year for the poorly graded till and sandstone scenario (Scenario #1) and 72 mm/year for the well graded till and mixed mine rock scenarios (Scenarios #2 and #3).

Effects of Suboxic Zones

Potential establishment of suboxia within the NAG backfill is a function of limiting re-supply of oxygen from the atmosphere, either laterally across angle of repose slopes of the backfilled mine rock, or vertically across the horizontal surface of the backfilled mine rock. Limiting airflow capacity across the horizontal surfaces can also limit lateral advective gas transport, in the absence of a limitation of the presence of a limitation on airflow capacity on the sloping backfilled surface, depending on the lift height of the backfilled mine rock. Initially, oxygen concentration in the pore-space of the backfilled NAG material will be atmospheric (nominally 20.9% by volume). Sulfide material within the NAG material will consume this oxygen; however, if re-supply of oxygen is limited as discussed previously, then the availability of further sulfide oxidation will be limited, thus creating suboxic conditions within each encapsulated cell. As oxygen decreases, and the geochemical conditions shift from oxic to suboxic, additional biological reactions that are favourable in the absence of oxygen may occur; however, to provide a conservative prediction of the effect of suboxic conditions, these biological reactions were

not included in any modelling. This is a substantively conservative approach given that in suboxic conditions, and provided there is opportunity and hydraulic residence time for denitrification, it is reasonable to postulate that bio-reduction of selenium will also occur (see MEND, 2015). Once suboxic conditions are established, the reactive transport model assumes that pyrite oxidation only occurs in the oxic zone nearer to the surface, while carbonate minerals can still react throughout the entire depth of the cell as their reactivity is not dependent on oxygen availability in the NAG backfill.

Given the geometry of the NAG backfill, and the different cell volumes and placement timing, zones of suboxia will vary based on the location of the cell in the NAG backfill. Cell-specific reactive and suboxic zone thicknesses for all cells were determined from the GeoStudio Oxygen Ingress Model results (Section 4.2). The development of suboxic conditions occurred at depths of roughly 13 m below the cover system in the poorly graded till and sandstone scenario and occurred within the 3.3 m cover system in both the well graded till and mixed mine rock scenarios. In order to remain conservative and capture sulfide oxidation and subsequent reactions occurring in the mine rock mix cover system, a depth to suboxic conditions of 3 m was used in the well graded cover system scenarios. Cell-specific reactive and suboxic zone thicknesses are summarized below in Table 3.12.

Table 3.12: Cell-specific reactive and suboxic zone thicknesses.

Cell	Total Cell Height (m)*	Reactive Zone Thickness (m)		Suboxic Zone Thickness (m)	
		Poorly Graded	Well Graded	Poorly Graded Scenario	Well Graded Scenarios
1	28	13	3	15	25

*Not including cover system

Construction Schedule

The construction schedules of the NAG backfill will influence timing of seepage quality. Placement of the cover system will limit oxygen ingress and NP into the NAG backfill as well as the maturing of the cover system vegetation. The construction schedule of both the backfill and cover system was simplified to allow for implementation into the reactive transport model. These simplifications and assumptions were:

- All cells are built instantaneously, and the complete height of the cell was available for reaction once it was placed in the model.
- Cover system placement for the backfill is indicated by the construction schedule provided by Telkwa and detailed in Section 3.5.1.
- Once covered, there will be an instantaneous decrease in NP.
- Once forest vegetation is developed (assumed to be five years after cover construction) there will be an instantaneous decrease in NP.
- Once covered, there will be an approximately 15-year period for suboxic conditions to develop. It was assumed there will be an instantaneous shift to suboxic conditions 15 years after cover construction.

Additional NAG Backfill Reactive Transport Model Assumptions

- Mineralogy was homogeneous throughout the NAG backfill and is defined based on the NAG mine rock barrel tests compositions;
- Mine rock placement in the NAG backfill will include mine rock characterized as the average composition from the mine rock barrel tests;

- Cell-specific annual loads (mg/year) were calculated based on the reactive transport concentration outputs and total annual flow volumes for each cell respectively;
- The timing of seepage from each cell of the reactive transport model was based on wetting-up timing from the GoldSim model. A cell was assumed to be wetted-up when total annual seepage from the GoldSim model was greater or equal to 50% of the steady state total annual seepage for that cell. Prior to a cell being wetted-up, parameter concentrations were set to equal the concentration from Year 0 of the reactive transport model. Seepage rates are negligible during the time the cell is wetting up, and therefore load from the cell is also negligible;
- After an initial wetting-up phase, final concentrations for the NAG backfill were calculated using the total annual loads (mg/year) from each cell divided by the total annual seepage rate (L/year);
- Seasonality was not included in the model. A constant NP based on bare surface, covered grass surface, or covered forest surface was assumed for all cells;
- Cell-specific seepage volumes and concentrations were mixed at the base of the NAG backfill based on the modelled seepage rates from the GoldSim model;
- The performance of the cover system remains constant;
- Parameter concentrations below detection limit were assigned values of the detection limit used in the barrel test leachate chemistry reporting;
- During the bare surface period, seepage and porewater is in equilibrium with the atmosphere ($\log(pO_2) = -0.7$ and $\log(pCO_2) = -3.5$); and
- During the cover period, pore water residing in the suboxic zone is in equilibrium with O_2 concentrations of 0.1% ($\log(pO_2) = -3.0$).

3.5.6.6 Geochemical Scale-Up Model

Parameters that were not included in the reactive transport model were modelled using a geochemical scale-up model. The geochemical scale-up model functioned by:

- Developing average loading rates for parameters not included in the reactive transport models using the leachate data from the B1, B2 and B7 barrel tests; and
- Scaling-up the production rates based on material placement, hydraulic properties, and material properties.

Soluble salts can accumulate before kinetic experiments are initiated and result in rapid flushing of constituents. Potentially due to the age of the weathering experiments or variations in collected water volumes it was not entirely apparent if the B2 and B7 barrel tests had fully flushed stored soluble salts; however, loading rates from the last three samples collected were used.

Similar to the reactive transport model, loading rates derived using the barrel leachate data were scaled up based on differences between the barrel test scale and the full backfill scale. The scale up included two scaling factors: particle size and mine rock contact. Temperature scaling factors were not applied as it was assumed that the average temperature in the barrels will be comparable to the full-scale NAG backfill.

Particle Size Factor

The reactive particle sizes of the NAG backfill were assumed to be limited to the < 6.35 mm portion and assumed to be 20% of the bulk mine rock; therefore, the scaling factor for particle size was set to 0.2. This particle size scaling factor was previously used by SRK (2022a) to scale HCT loading rates to field scale.

Contact Factor

The reactivity of the mine rock will be limited to the < 6.35 mm portion; however, only a portion of the seepage will react with this portion given the likely presence of preferential flow paths. A contact factor of 0.5 was used in previous source term development (SRK, 2022a) and was deemed reasonable for the current model.

Geochemical Scale-Up Model Assumptions

The following assumptions were included in the geochemical scale-up model:

- Cell-specific annual loads (mg/year) were calculated based on the annual mass of mine rock for the cell in the given year and the loading rate of the parameter (mg/kg/year). After an initial wetting-up phase, final concentrations for the NAG backfill were calculated using the total annual loads (mg/year) for all cells divided by the total annual seepage rate (L/year);
- The wetting up period for the backfill was estimated as the period of time prior to total annual seepage volumes equalling roughly 50% of steady state annual seepage volumes (roughly 17 years). Seepage concentrations prior to wetting up were set to concentrations calculated for the first year after wetting up;
- Once a cell was fully constructed and wetted-up, the annual loads were assumed to remain constant and estimated parameter concentrations were only influenced by changes in annual seepage rates;
- The seepage of all cells mixed at the base of the NAG backfill;

- Loading rates remained constant and were not affected by changes in mineralogy or kinetic rates over time; and
- Solubility controls were applied by including the geochemical scale-up modelled parameters in the equilibrium modelling discussed in Section 3.5.6.5.

3.5.7 Nitrogen Sensitivity Scenarios

Two additional model sensitivity scenarios were simulated to assess nitrogen source terms under different blasting loss conditions. A high nitrogen source term scenario was run to simulate a scenario where nitrogen losses from blasting are greater than expected. A low nitrogen source term scenario was run to simulate decreased nitrogen losses from blasting resulting from blast hole liners used as a source mitigation.

Nitrogen source term scenarios were modelled by either increasing or decreasing the residual nitrogen available for leaching as calculated by Ferguson & Leask (1988). This in turn increased or decreased the initial pore-water concentration of nitrogen species applied in PHREEQC for the respective nitrogen scenarios (Table 3.13). All other reactive transport model inputs remained the same as in the Well-Graded with No Internal Layers models. The high nitrogen source term scenario represents an increase of 56.25% residual nitrogen. Blasthole liners are assumed to decrease nitrogen losses by 37.5% in the low nitrogen source term scenario (D. Farmer, personal communication, July 15, 2024).

Table 3.13: Initial nitrogen species concentrations in NAG backfill porewater for nitrogen source term scenarios.

Parameter	Unit	Initial Porewater Composition		
		Well-Graded No Internal Layers Scenario	High Nitrogen Scenario	Low Nitrogen Scenario
Nitrate (as N)	mg/L	65	102	41
Ammonia (Total)	mg/L	8.3	13	5.2
Nitrite (as N)	mg/L	1.5	2.4	0.94

4 MODELLING RESULTS AND DISCUSSION

4.1 Water Balance Results

A landform water balance was completed to develop simplified boundary conditions for the 2D GeoStudio oxidation modelling and the 3D GoldSim modelling. A summary of the 1D water balance for the two material combination scenarios is provided in Table 4.1. The well-graded till and mine rock mix material properties and results were also used for the no internal layers scenario.

Table 4.1: Summary of water balance results for the two material combination scenarios.

Scenario	Total Precipitation (mm)	Rainfall (% of PPT)	Snow (% of PPT)	Actual Evapotranspiration (% of PPT)	Runoff (% of PPT)	Sublimation (% of PPT)	Net Percolation (% of PPT)
PG Till and Sandstone (Bare)	649	61%	39%	32%	2%	24%	42%
PG Till and Sandstone (Grass – 5 years)	616	52%	48%	49%	0%	19%	32%
PG Till and Sandstone (Forest – 73 years)	655	61%	39%	57%	3%	21%	19%
WG Till and Mine Rock Mix (Bare)	649	61%	39%	42%	12%	24%	22%
WG Till and Mine Rock Mix (Grass – 5 years)	616	52%	48%	54%	3%	19%	24%
WG Till and Mine Rock Mix (Forest – 73 years)	655	61%	39%	59%	9%	21%	11%
Mine Rock Mix (Bare)	649	61%	39%	28%	28%	21%	22%*

PG Till – Poorly Graded Till; WG Till – Well Graded Till; PPT – Precipitation

* - Surface net infiltration into the bare Mine Rock Mix

An average year of daily net percolation rates for each time period (bare, grass, and forest) were used as inputs in the 2D GeoStudio models and stochastically in the 3D GoldSim model.

4.2 2D GeoStudio Oxidation Model Results

The predicted development of the suboxic zone within the NAG backfill mine rock within the Open Pit with time for the poorly graded till and sandstone mine rock scenario is shown in Figure 4.1. The suboxic zone development for the well graded till and mine rock mix scenario is shown in Figure 4.2, while the suboxic zone development for the scenario with no internal overburden layers is shown in Figure 4.3. The models indicate that the long-term depths to suboxia are, on average, 13 m for the poorly graded till with sandstone mine rock scenario and 3.3 m for the well graded till with the mine rock mix scenario, as well as the no internal overburden layers scenario. The suboxic zone takes approximately 15 years to form in each strip in the poorly graded till with sandstone mine rock scenario. In both the well graded till with the mine rock mix scenario and the no internal layers scenario (using well graded till and mine rock mx material properties), it took approximately 13 years for the suboxic zone to form in each strip. These results were used to estimate the development of the suboxic zone within the 3D GoldSim model.

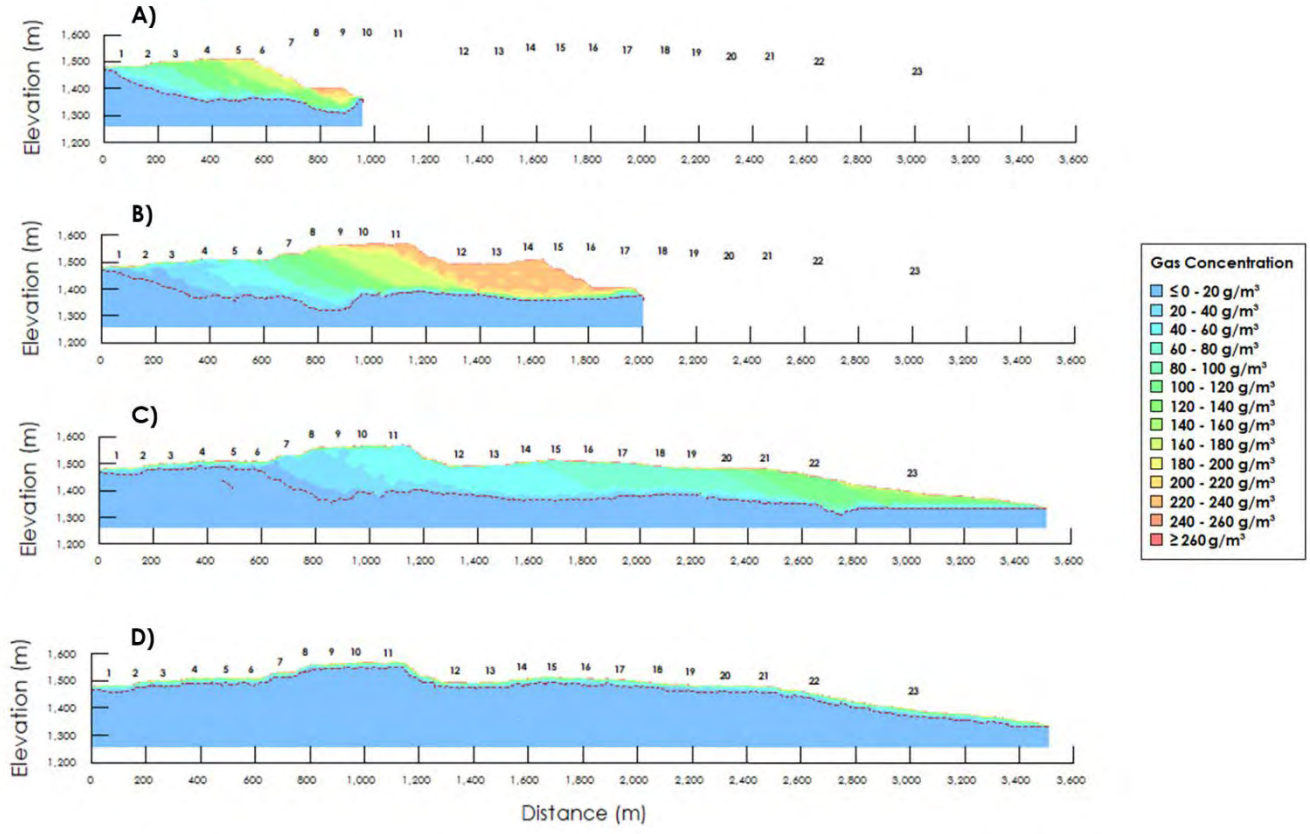

Figure 4.1: Development of suboxic zone for the poorly graded till and sandstone mine rock scenario (outlined by red dashed line in figures, which represents the zone at, or below, an O_2 concentration of 13 g/m³ or 1 vol.%) for the poorly graded till and sandstone mine rock scenario at A) Year 12; B) Year 17; C) Year 23; and d) Year 36/Long Term.

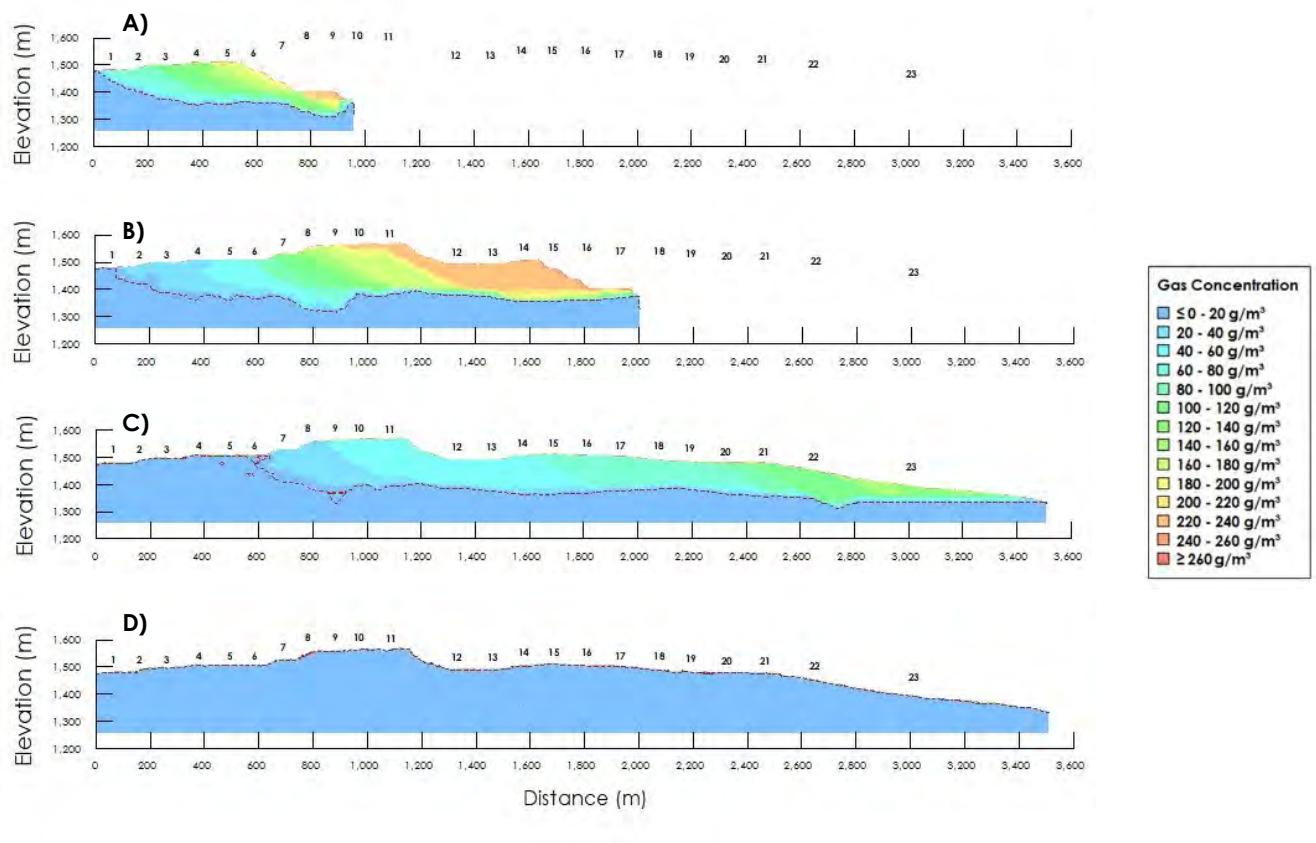

Figure 4.2: Development of suboxic zone (outlined by red dashed line in figures, which represents the zone at, or below, an O_2 concentration of 13 g/m³ or 1 vol.%) for the well graded till and mine rock mix scenario at A) Year 12; B) Year 17; C) Year 23; and d) Year 36/Long Term.

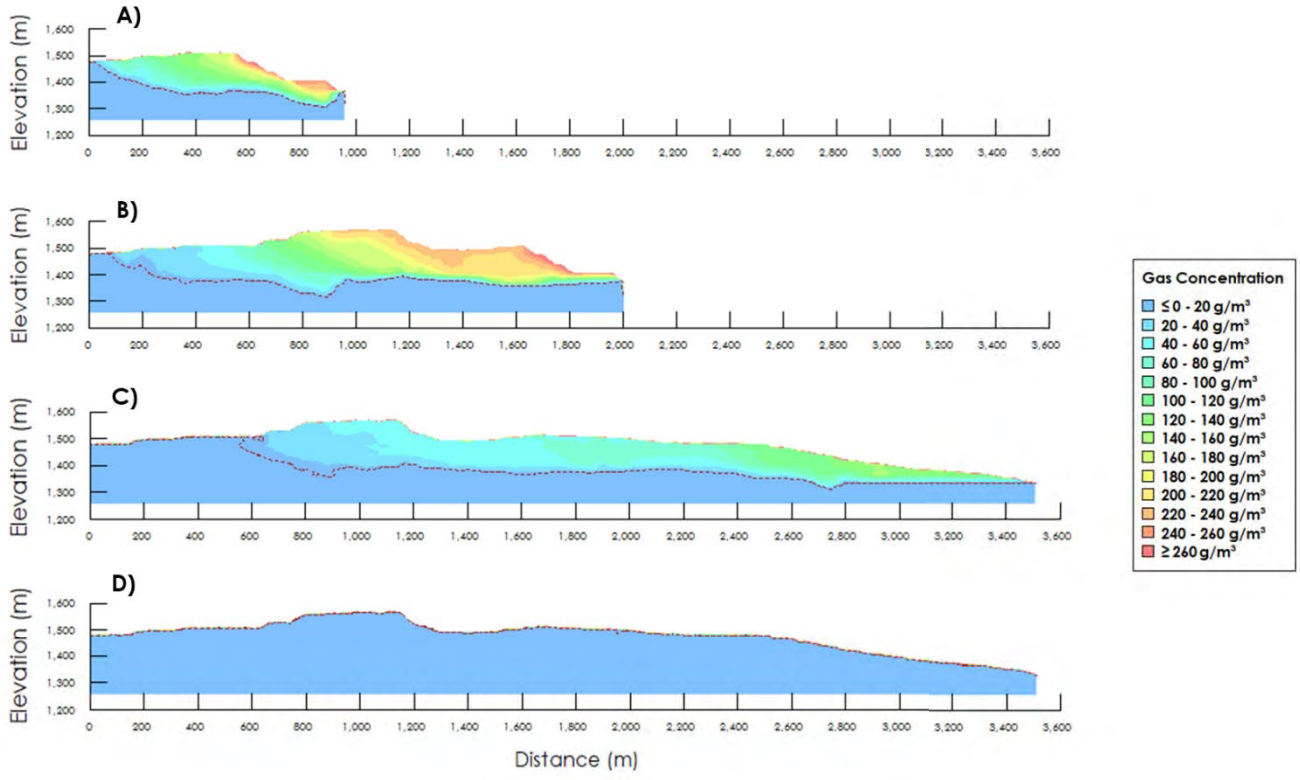

Figure 4.3: Development of suboxic zone (outlined by red dashed line in figures, which represents the zone at, or below, an O_2 concentration of 13 g/m³ or 1 vol.%) for the no internal layers scenario at A) Year 12; B) Year 17; C) Year 23; and d) Year 36/Long Term.

4.3 3D GoldSim Model Results

The 3D GoldSim model was run on calendar time with 2023 representing the first year of placement, or Year 6. The results are therefore presented in calendar time out to 2150, which represents Year 133.

4.3.1 Total Seepage

The total seepage rate of the backfilled NAG mine rock in the Open Pit was simulated in GoldSim for 100 realizations. The mean value, along with the 5th and 95th percentiles of the model results, are plotted in Figure 4.4 for all modelled scenarios. The models predicted long-term stabilized seepage rates from the covered and vegetated backfilled NAG mine rock that were between 31,000 m³/month and 36,000 m³/month for the poorly graded till and sandstone mine rock scenario, and between 14,500 m³/month and 16,000 m³/month for both the well graded till with mine rock mix scenario and the no internal layers scenario. The poorly graded till and sandstone mine rock scenario showed greater variability in monthly seepage rates due to the coarser texture of the material. Prior to cover system placement, the well graded till with mine rock mix scenario differs from the no internal layers scenario

due to the lack of overburden layers, but once the cover system is placed, the two scenarios show almost identical results.

The model results indicate that the backfilled NAG mine rock in the Open Pit will be wetted up, as indicated by the stabilization of the seepage rates, approximately 40 years following completion of construction for the poorly graded till and sandstone mine rock scenario. The finer texture of the material in both the well graded till with mine rock mix scenario and the no internal layers scenario resulted in a longer wetting up period, reaching stabilization approximately 80 years following the completion of construction.

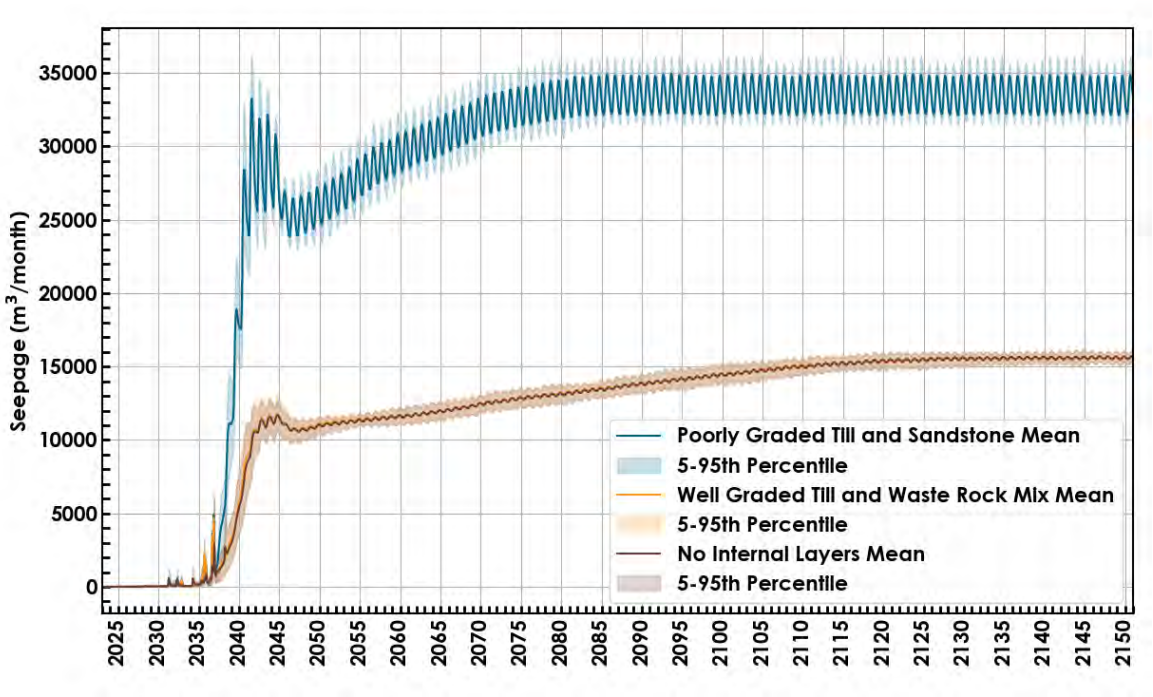

Figure 4.4: Range of seepage rates simulated by the GoldSim model for the backfilled NAG mine rock in the Open Pit for all the scenarios.

4.3.2 Total Storage

The estimated total stored water volume within the backfilled NAG mine rock for the modelled scenarios are shown in Figure 4.5. The modelled water volume increases with mine rock placement during construction before starting to stabilize once construction is complete and the cover system is placed. Similar to the seepage results, the water volume within the backfilled NAG mine rock is estimated to stabilize after approximately 40 years for the poorly graded till and sandstone mine rock scenario and approximately 70-80 years for both the well graded till with mine rock mix scenario and the no internal layers scenario. Once the stored water volume stabilized, very small variations in water volume were predicted, due to the variation in seasonal NP inputs.

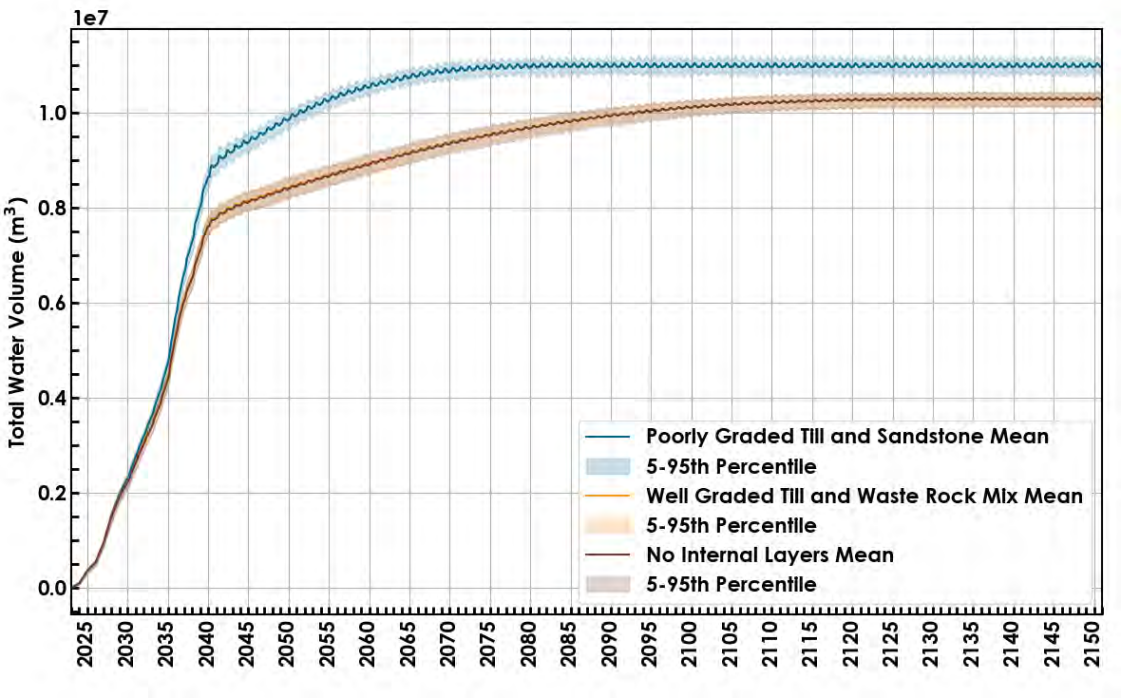

Figure 4.5: Range of total water volume within the backfilled NAG mine rock in the Open Pit simulated by the GoldSim model.

4.3.3 Oxygen Ingress

The range of oxygen ingress from the 3D GoldSim model for all modelled scenarios is presented in Figure 4.6. The well graded till with mine rock mix scenario and the no internal layers scenario both showed a higher long term average oxygen ingress despite having a shallower depth to suboxia. Due to the limitations of the GoldSim model representing each strip as a 1D column, convection is limited to density driven convection (free convection) and oxygen ingress is dominated by diffusion. In this case, with a shallower depth to suboxia, the concentration gradient across the cover system is greater, resulting in a higher diffusive oxygen ingress rate. In the poorly graded till and sandstone mine rock scenario, the depth to suboxia is greater, reducing the concentration gradient across the cover system and lowering the overall diffusive flux. When forced convection (advection) is accounted for, it is likely that the oxygen ingress rate for the poorly graded till and sandstone mine rock scenario would show higher oxygen ingress rates.

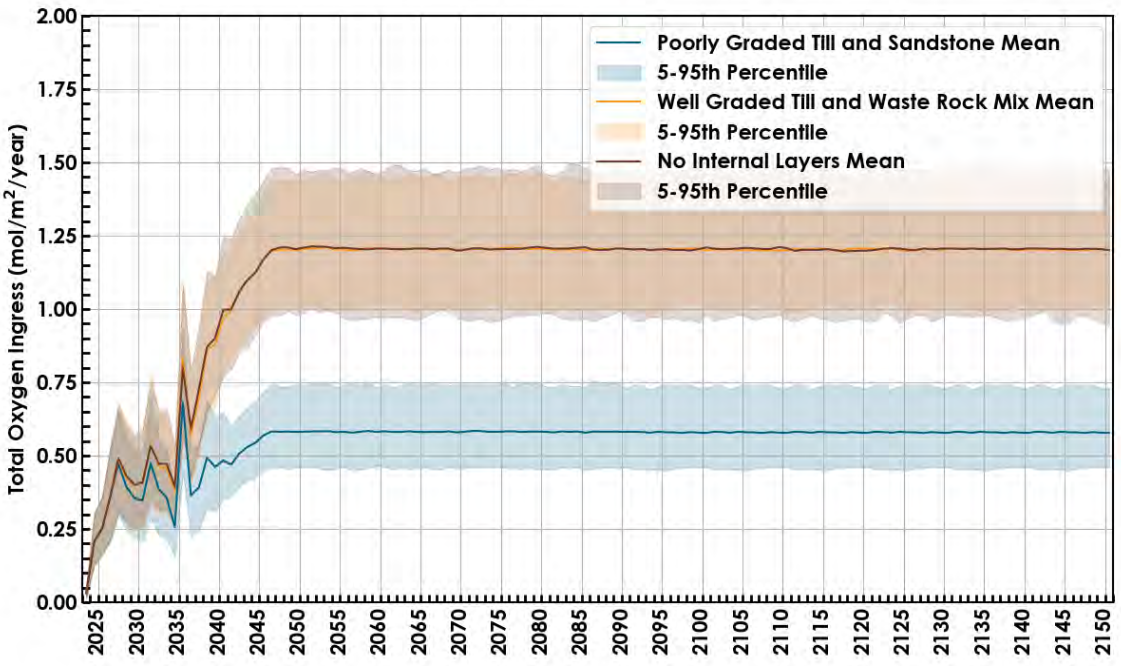

Figure 4.6: Range of oxygen ingress rates simulated by GoldSim for the backfilled NAG mine rock in the Open Pit for all modelled scenarios.

4.4 Geochemical Modelling Results

This section summarizes the results of the geochemical models of the NAG backfill cover scenarios and present a time-series of source terms for the NAG backfill during the bare surface, covered grass surface, and covered forest surface timeframes. Model results of select parameters are presented in Figure 4.7 to Figure 4.11. Tables of source terms and annual loads from the three scenarios of the NAG backfill are provided in Appendix A.

In the three modelled scenarios, the cover system construction decreases NP and limits oxygen ingress into the mine rock within the NAG backfill. Suboxic zones were established in almost half of the cells in the poorly graded till and sandstone mine rock scenario and in all but one cell in the well graded till and mine rock mix scenarios (Section 4.3.3). Sulfide oxidation only occurred in the reactive oxic zones, as a result, loading rates of oxidation products are partly controlled by the amount of suboxic mine rock in the backfill.

In general, concentrations for most modelled parameters were similar between the poorly graded till and sandstone and well graded till and mine rock mix scenarios. While the amount of suboxia increased substantially for the well graded till and mine rock mix scenarios, the volume of water infiltrating the surface of the NAG backfill decreased, resulting is less water available to dilute oxidation products from the limited reactive zone. Despite concentrations remaining similar between the three scenarios, the

annual load exiting the NAG backfill as seepage in both the well graded till and mine rock mix scenarios is roughly half the annual load exiting in the poorly graded till and sandstone scenario.

The onset of seepage from the NAG backfill occurs as cells from the model become fully wetted-up, which begins in approximately 2036. Areas of the backfill that contain smaller thicknesses of mine rock wet up faster than areas with greater thicknesses; therefore, the effects of seepage from thinner cells are observed in the model results faster than the effects from thicker cells. Thicker cells will generally produce poorer water quality than thinner cells because there is a longer pathway for water to accumulate oxidation products (ignoring the effects of suboxic zones).

After the initial wetting-up period and prior to the development of suboxic zones within the models, concentrations of parameters associated with pyrite oxidation (e.g., SO_4, Se, Cu, etc.) generally have an increasing trend. Concentrations stabilize and tend to decrease once suboxic conditions are established. After the onset of seepage, Se concentrations range between 0.03 to 0.07 mg/L, with the onset of lower concentration occurring near the end of the modelled timeframe. Concentrations of Se are trending lower near the end of the modelled timeframe for the well graded till and mine rock mix scenario. Concentrations of SO_4 and Cu are approximately 1,500 mg/L and 0.015 mg/L, respectively, near the end of the modelled timeframes for all three scenarios. Annual loads of parameters related to pyrite oxidation in the well graded till and sandstone scenarios are approximately half of the poorly graded till and mine rock mix scenario. Annual loads are generally similar between the two well graded till and waste rock mix scenarios with the largest differences observed in the last ~20 years of the modelled timeframe.

Nitrate concentrations and loads peak in the initial years that seepage occurs and are controlled by flushing of blast residues that are on the surface of the mine rock. The release of NO_3 (and subsequently NO_2 and NH_4) is spread out over many decades as the transport time is variable in different areas of the backfill depending on the cell thickness.

A slight variation in pH was observed between the modelled scenarios with the well graded till and sandstone scenarios having a slightly higher value. This is likely a result of the longer residence time of water in the suboxic zone of the carbonate-rich mine rock in the well-graded model scenario.

The NAG backfill source terms from the three modelled scenarios are summarized in Table 4.2 and represent the concentrations of parameters at the end of the modelled timeframe (year 2150). The source terms are also compared to source terms developed by SRK (2024). It should be noted that source terms developed by both SRK and Okane utilized NAG field bin data to derive source terms. Differences in source terms are attributed to the implementation of reactive transport modelling and the consideration of changes in net percolation and oxygen ingress into the NAG backfill as a result of the modelled cover systems. In general, the source terms from the current modelling work are lower than the initial SRK source terms. Due to the incorporation of wetting up in the current model, the largest differences in loading rates between both sets of models are observed in the initial 20 years of the model

time frame. Once the modelled loading rates stabilize, mass loads of constituents such as SO_4 and Se range from approximately 50 to 75% lower than the initial SRK loads (Figure 4.12).

[1] Source term represents the parameter value at the end of the modelled timeframe (year 2150).

[2] Source term from SRK (2024).

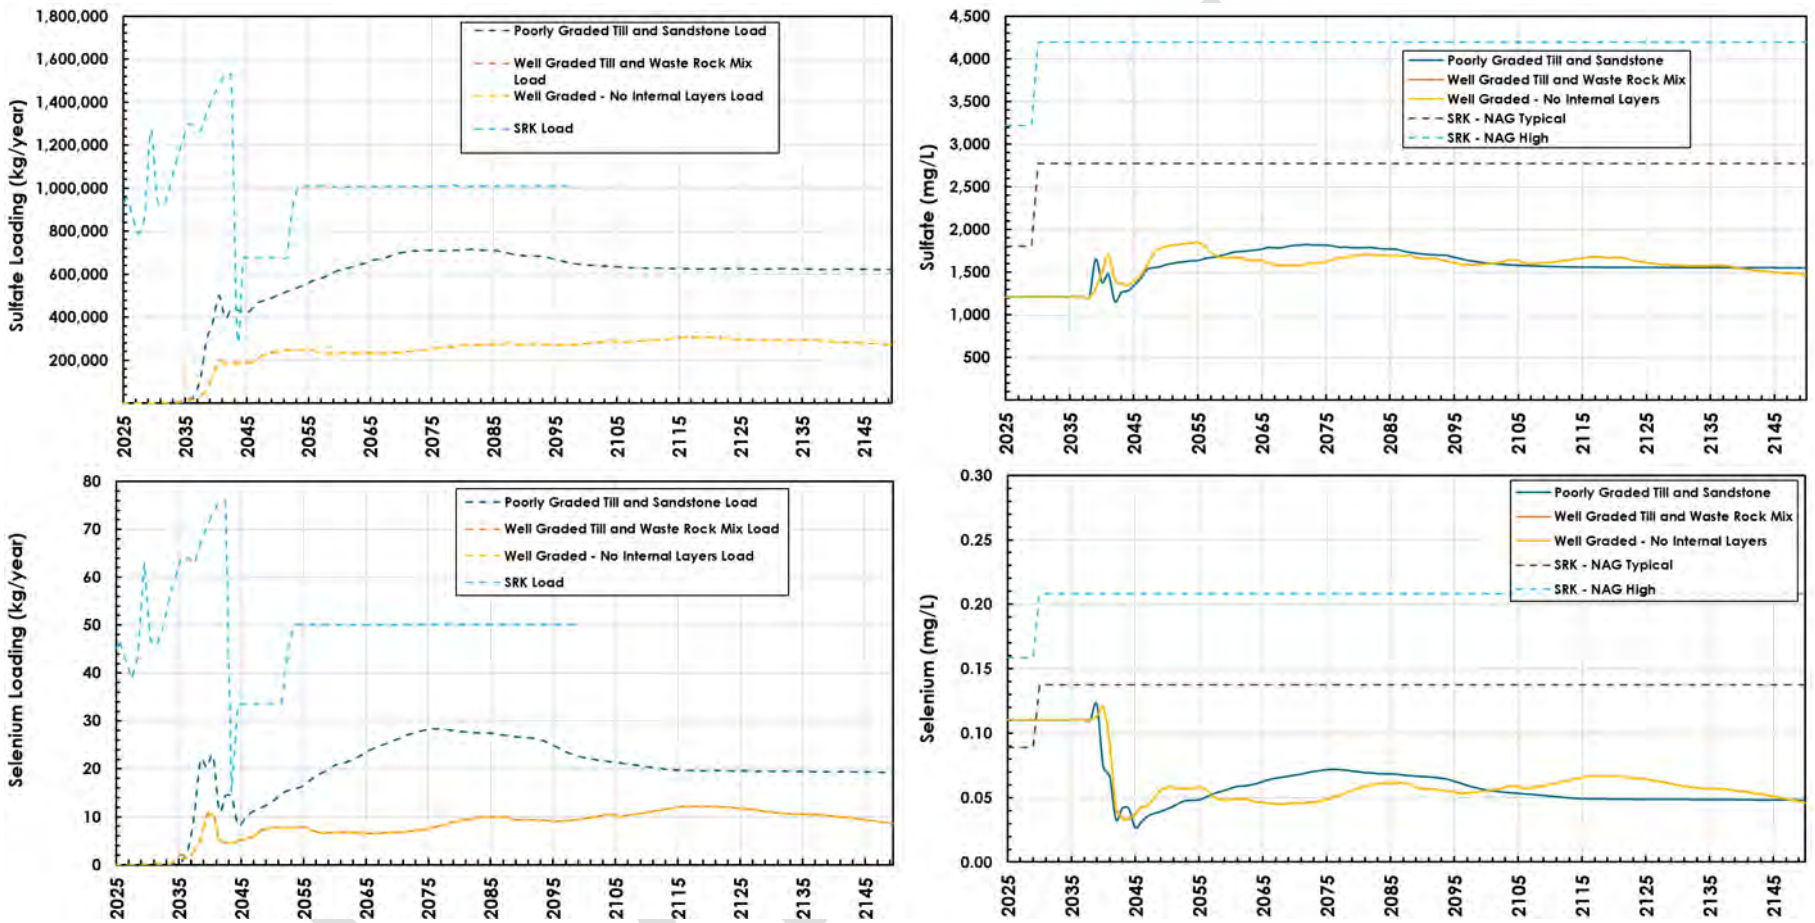

Figure 4.12: Summary of sulfate and selenium NAG backfill source terms and loading rates.

4.4.1 Nitrogen Source Term Scenarios

Nitrogen source terms decreased by 37.5% in the low nitrogen scenario and increased by 56.25% in the high nitrogen scenario throughout the first 15 years of the modelled timeframe as the initial porewater from each cell flushed out (Figure 4.13). Once individual cells began to be fully flushed, there were small variations in the percent change in nitrogen concentrations across sensitivities caused by dilution from cells that had been fully flushed of nitrogen. Overall, the differences in nitrogen source terms were similar to the 37.5% decrease or 56.25% increased applied in the respective sensitivity.

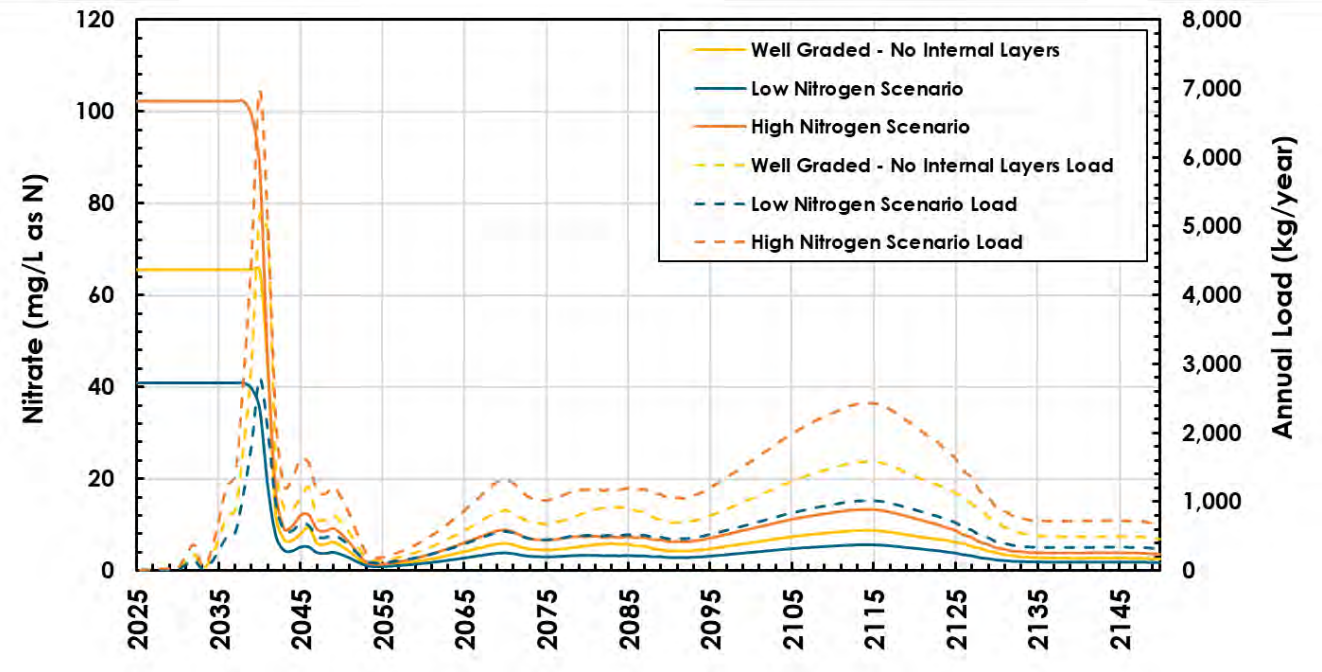

Figure 4.13: Summary of nitrate source terms and loading rates in the well graded – no internal layers scenario and two nitrogen source term scenarios.

5 CONCLUSIONS

The scope of this work was to provide Telkwa support in the development of source terms for three scenarios of backfilled NAG mine rock in lifts using bottom-up construction methodology with overburden covers. The objective of the backfilled design is to limit oxygen and water ingress to minimize the release of potential contaminants of concern such as selenium and sulfate to the receiving environment. Based on the modelling that was completed for this work, the following conclusions are made:

- GoldSim modelling indicates that the backfilled NAG mine rock in the Open Pit will be wetted up approximately 40 years following completion of construction for the poorly graded till and sandstone mine rock scenario. The well graded till with mine rock mix scenario and the no internal layers scenario will be wetted up approximately 80 years following the completion of construction due to the finer texture of material.

- Two-dimensional oxygen models indicate that the long-term depths to suboxia are, on average, 13 m for the poorly graded till and sandstone mine rock scenario and 3.3 m for the well graded till with mine rock mix scenario and the no internal layers scenario. The suboxic zone takes approximately 15 years to form in each strip modelled of the poorly graded till and sandstone mine rock once the cover system has been placed. In both the well graded till with mine rock mix scenario and the no internal layers scenario, the suboxic zone takes approximately 13 years to develop following cover system placement.

- It is likely that the oxygen ingress rate for the poorly graded till and sandstone mine rock scenario would be greater than the well graded till and mine rock mix scenarios.

- In general, concentrations in NAG backfill seepage for most modelled parameters will be similar between the three modelled scenarios.

- The decrease in oxygen ingress and infiltrating water into the NAG backfill for the well graded till and mine rock mix scenarios results in an annual chemical load (mass released per year) decrease of approximately half compared to the poorly graded till and sandstone mine rock scenario.

- As a result, mass loads of dissolved constituents such as selenium and sulfate from the NAG backfill are expected to decrease relative to initial source term and load balance models under the conditions modelled herein.

The NAG backfill source terms from this modelling work will be integrated into the site wide load balance model to quantify the effects of the backfill on water quality around the Tenas project.

Executive Summary

As part of the Tenas Project Environmental Assessment, SRK Consulting (Canada) Inc. was retained by Telkwa Mining Ltd (TCM) to complete a hydrometeorological analysis for the Tenas Project (the Project).

The Project is located approximately 25 km southwest of the town of Smithers, BC within the Telkwa River watershed and is composed of an open pit, backfill, external stockpiles, water management ponds, control ponds, process plant and rail load out.

This report presents the hydrometeorological baseline of the Project. The key objective of this report is to to develop inputs to the Project water management plan and water and load balance model.

Site hydrometeorological conditions are monitored via a site weather station and five (5) hydrometric stations located on each of the major watercourses (Goathorn-Hydro, Telkwa-Hydro, Tenas-Hydro/Tenas-Hydro B, and Four-Hydro). The weather station was operated from 2017 to 2022. Hydrometric stations have two to three complete hydrologic years of data recorded within the 2017 to 2022 period. For this assessment, the relatively short site datasets are supplemented with regional datasets and climate re-analysis models.

Synthetic long-term Project climate datasets were developed based on transposing the regional datasets at Smithers Airport to the site and adjusting for observed orographic effects. These datasets were used to derive Project design parameters and water and load balance inputs, as well as to support development of a rainfall-runoff model. This model was developed and calibrated for each of the local hydrometric stations. A combination of the calibrated models from Goathorn Creek and Tenas Creek were applied to the Tenas Project area.

Selected climate parameters are summarized in Table 1-1 to Table 1-3.

Table 1-1: Derived Monthly and Annual Project Climate Normals

Parameter	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
Average Temperature (°C)	-9.2	-6.1	-2.7	2.1	6.8	10.7	13.0	12.5	8.4	2.6	-3.8	-7.9	2.2

1000	159.4	269.9

Source: \\srk.ad\dfs\na\van\Projects\01_SITES\ \Telkwa Coal\1CT027.003_2020 EA Water Management\500_Water_Balance\Model\SnowmeltModel\SWE_ModelledOutput_09172020.xlsx

Mean annual runoff for the Project was determined to be 219 mm/year with an annual runoff coefficient of 0.36 with the highest flows occurring in May and June due to freshet, and low flows occurring during the winter.

Climate change scenarios for RCP4.5, RCP6.5 and RCP8.5 were evaluated for the Project Area. The effects of the RCP4.5 scenario were used to generate mean annual and monthly temperature and precipitation correction factors, which also affect runoff and evaporation rates, as summarized in Table 1-4.

Table 1-4: Projected Climate Change Impacts on Selected Climate Parameters

Timeframe	Mean Annual Temperature (°C)	Mean Annual Precipitation (mm)	Mean Annual Evaporation (mm)
2011-2040	1.2°C	+5%	+2%
2041-2070	2.4°C	+12%	+4%
2071-2100	3.0°C	+15%	+5%

Source: compiled in text from R code \\srk.ad\dfs\na\van\Projects\01_SITES\Telkwa Coal\1CT027.003_2020 EA Water Management\200_Meteorology_Update\Rwork\Climate_Change_rev03.Rmd

Extreme precipitation magnitudes are expected to increase. Monthly streamflow is expected to experience an overall increase in flow magnitude and a shift to an earlier spring freshet. No significant trend in peak flows is projected.

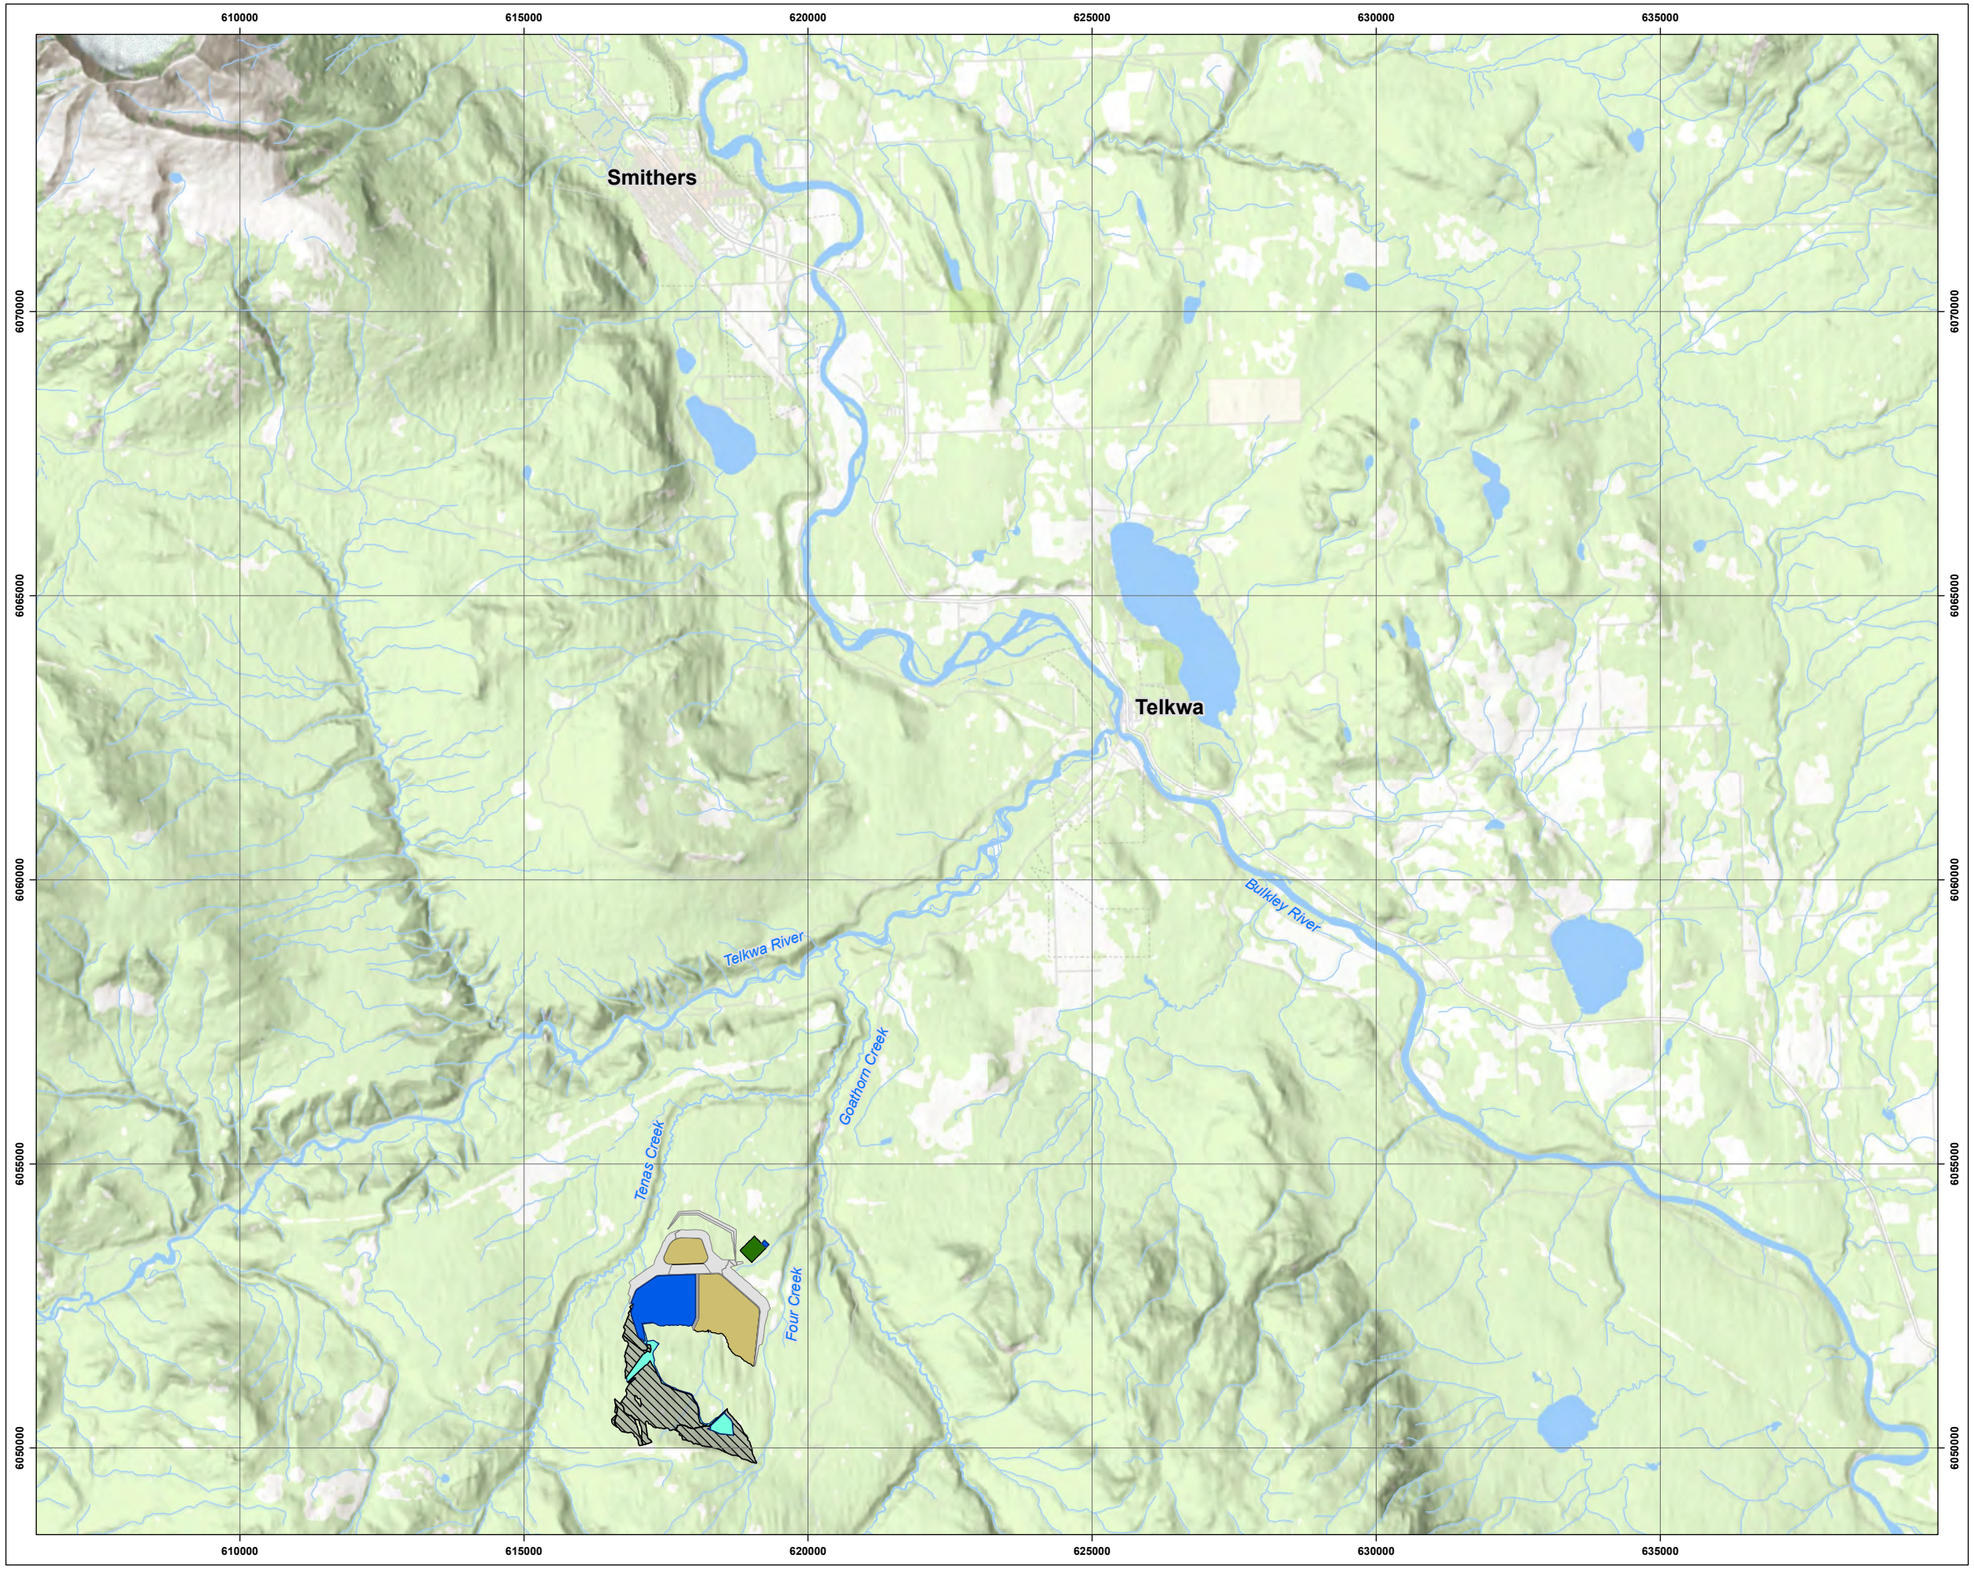
The short duration of the Project meteorological and hydrometric datasets is a limitation of this hydrometeorological baseline report. SRK recommends ongoing monitoring of Project meteorologic conditions, and continued hydrometric station monitoring at Four-Hydro and Tenas-Hydro B as a minimum.This report should be updated when additional data become available. In particular, the Four-Hydro discharge record requires additional flow measurements to characterize baseline conditions for effects assessments and to support predictive modelling.

1 Introduction

SRK Consulting (Canada) Inc. has been tasked with updating the meteorological and hydrological characterization to develop inputs required for the Tenas Project (the Project) in support of the Environmental Assessment (EA). The EA has been prepared in accordance with the BC Environmental Assessment Office (BC EAO) Guidelines for Preparing Environmental Assessments (BC EAO 2016).

The following report provides an updated summary of baseline meteorology and hydrology data collected between 2017 and 2022. Regional records were used to extend the local records in order to develop statistical climate and hydrologic parameters that will be used to support various technical studies for the EA, including water management designs, groundwater modeling, and the water and load balance model. The main changes pertain to the updating of the synthetic climate record based on additional data from the local station since the development of the EA baseline report (SRK 2022a) and the hydrological parameters based on new calibration to the available data.

1.1 Project Setting



The Tenas Coal Project is a proposed coal mine located in the Coast Mountains of the Cordilleran Region near the Town of Telkwa approximately 25 km southwest of Smithers, British Columbia. The coal preparation plant, maintenance facilities and service facilities would be located approximately 6 km southwest of Telkwa. The Project footprint elevation ranges from 750 to 1050 meters above sea level (masl) with a median elevation of 800 masl. The Ministry of Environment and Climate Change Strategy (MECCS) have published hydrological zones that represent areas of homogeneous hydrologic and geomorphic characteristics. The Tenas Project is within Zone 8 – Nechako Plateau.

The Project encompasses the lower reaches of the Telkwa River, Tenas Creek, Goathorn Creek and Four Creek. The Telkwa River is a major tributary to the Bulkley River near the village of Telkwa, British Columbia, which ultimately flows into the Skeena River. Four Creek is a tributary of Goathorn Creek, and Goathorn Creek and Tenas Creek are tributaries of the Telkwa River.

Figure 1-1 shows the Project location.

1.2 Scope of Report

Meteorology and hydrology studies conducted as part of the Telkwa Coal Project Prefeasibility studies (SRK 2017a, 2017b) identified gaps in the existing meteorological and hydrological datasets. Site specific hydrometeorological data started being collected in 2017. The first years of records (2017-2019) wereused by SRK to develop a hydrometeorological baseline for the site (SRK, 2022). Project data collection continued between 2020 and 2022. These new records were incorporated into the hydrometeorological analysis to support Project advancement in 2022 and are documented in this report.

This report is an update to the the baseline Project climate and hydrology previously developed by SRK (SRK, 2022) and generates projections of future climate conditions. This update includes available data up to October 2023.

- Section 2 presents the available meteorological datasets (2017-2022)
- Section 3 presents the available hydrometric datasets (2017-2022)
- Section 4 describes how available datasets were used to develop the Project Area meteorology and hydrometric synthetic time series
- Section 5 outlines how climate change impacts on Project air temperature, precipitation, lake evaporation and streamflow were evaluated from 2022 onwards.

2 Baseline Meteorology

2.1 Section Overview

Meteorological characteristics are typically assessed by integrating Project-specific and regional meteorology records as well as comparing previous studies related to the Project and regional indices. Placing the Project-specific parameters in context using regional analyses is important to be able to provide meteorological inputs to the Project based on extended periods of record.

2.2 Available Meteorological Data

Baseline meteorological monitoring was initiated at the Telkwa Coal Project site in September 2017 by ERM Consultants.

This section summarizes the available monitoring data for the Telkwa Coal Project. Regional climate data from the surrounding area has also been assessed to place the Telkwa Coal Project climate into context.

2.2.1 Project Data

Baseline climate data for the Project Area was collected at the Tenas Deposit automatic weather station (54.59° N, 127.19° W), installed on 29 September 2017 and operated through September

2022. Figure 2-1 illustrates the location of the Tenas Deposit Station and Table 2-1 provides the metadata.

The monitoring record from the Tenas Deposit Station was compiled, reviewed, and validated by ERM (ERM 2019). The following data is recorded at the weather station:

- Hourly average wind speed
- Hourly wind direction and standard deviation of wind direction for 2017
- Hourly average air temperature
- Hourly average relative humidity
- Hourly average solar radiation
- Hourly average barometric pressure
- Hourly sampled snow depth
- 5-minute and hourly accumulated total precipitation

Details concerning the meteorological station configuration, data collection and preliminary gap-filling procedures are outlined in Section 4 of The Tenas Project 2017 to 2019 Baseline Report (ERM 2019).

2.2.2 Regional Data

Regional meteorological data for British Columbia is available from private as well as provincial and federal government sources. Regional re-analysis products for historical climate and future scenarios are available as gridded products developed by third parties based on government datasets. Within the Nechako Plateau hydrological zone, there are over 90 regional meteorological stations monitored by the Meteorological Service of Canada (MSC). This division of Environment and Climate Change Canada provides public historical meteorological data and information.

Figure 2-1 illustrates the locations of selected regional meteorological stations with respect to the Project. Three stations have historically operated in the town of Smithers. Smithers Airport Auto and Smithers A are understood to be the same station, after an upgrade in 2018. Table 2-1 presents the metadata for the selected regional stations.

Table 2-1: Regional Meteorological Station Selections

Station Name	Climate Identifier	Latitude [° N]	Longitude [° W]	Elevation [masl]	Record Start	Record End	Distance from Project [km]
QUICK	1076638	54.62	126.90	533	1962	1995	19.1
SMITHERS AIRPORT AUTO	1077501	54.82	127.19	518	2013	2023	25.2
SMITHERS A	1077500	54.82	127.18	522	1942	2018	25.2
SMITHERS	1077499	54.83	127.18	523	2010	2023	26.3
HOUSTON	1073615	54.40	126.67	610	1957	2023	40.0
TOPLEY LANDING	1078209	54.82	126.16	722	1962	2017	71.0
EQUITY SILVER	1072692	54.2	126.28	1280	1981	2021	73.6
SUSKWA VALLEY	107G879	55.29	127.17	534	1982	2023	77.5
BURNS LAKE DECKER LAKE	1091174	54.38	125.96	713	1990	2023	83.1

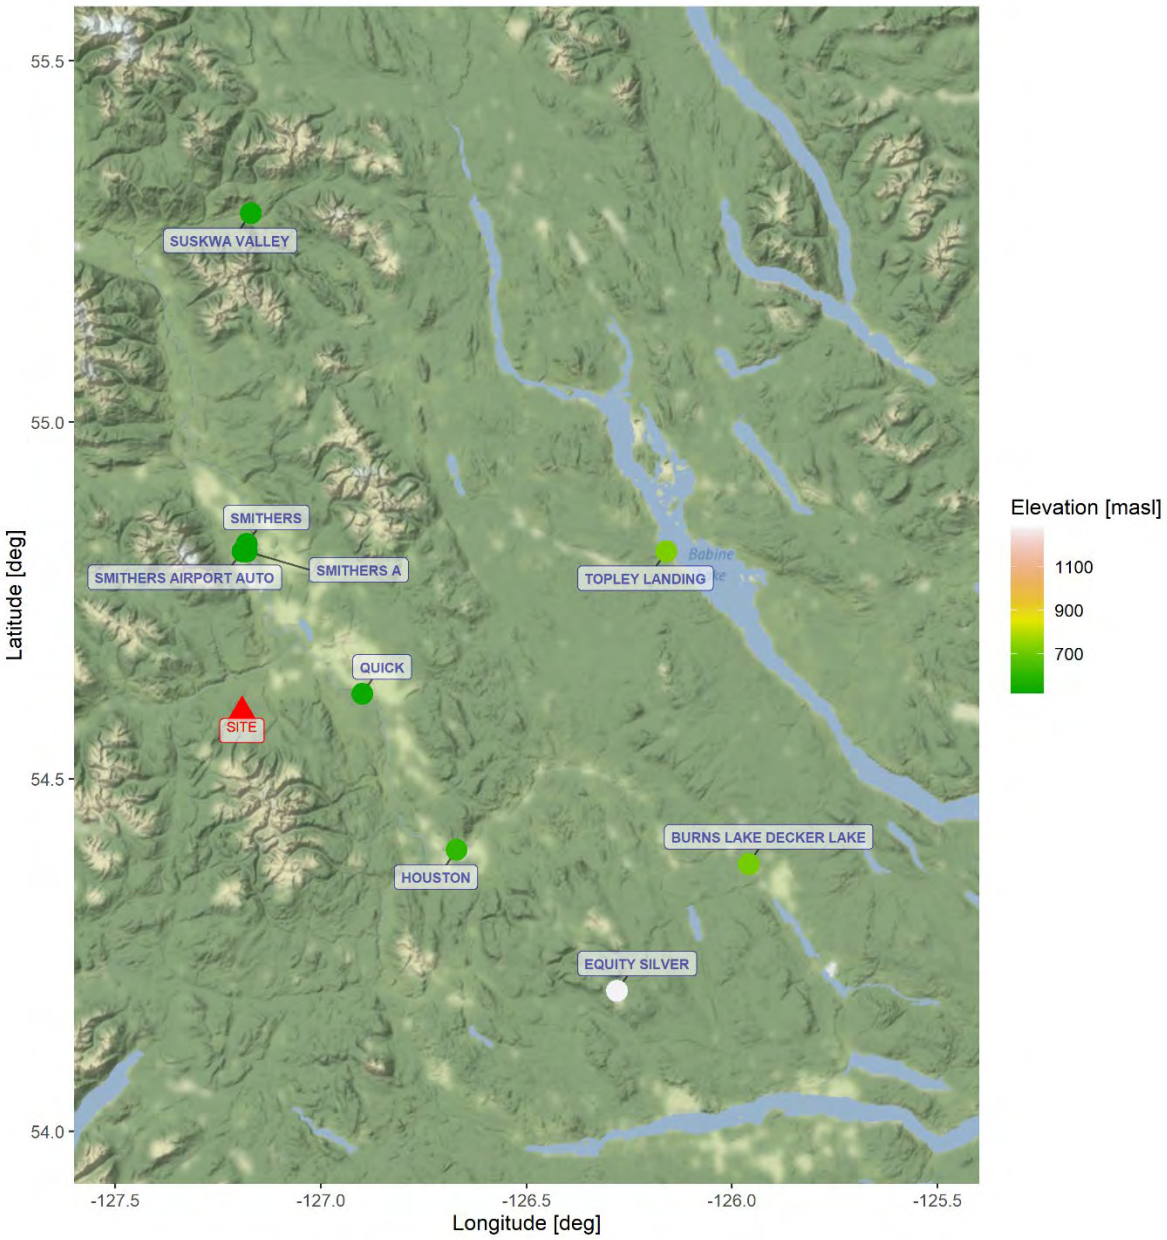

Figure 2-1: Meteorological Stations Used in Project ("Site") and Regional Assessment

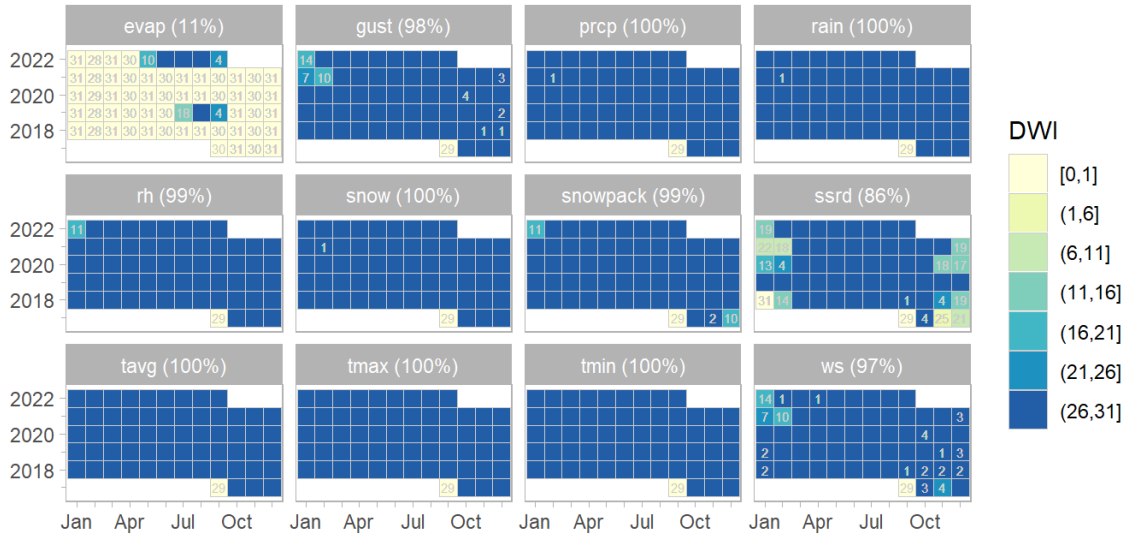


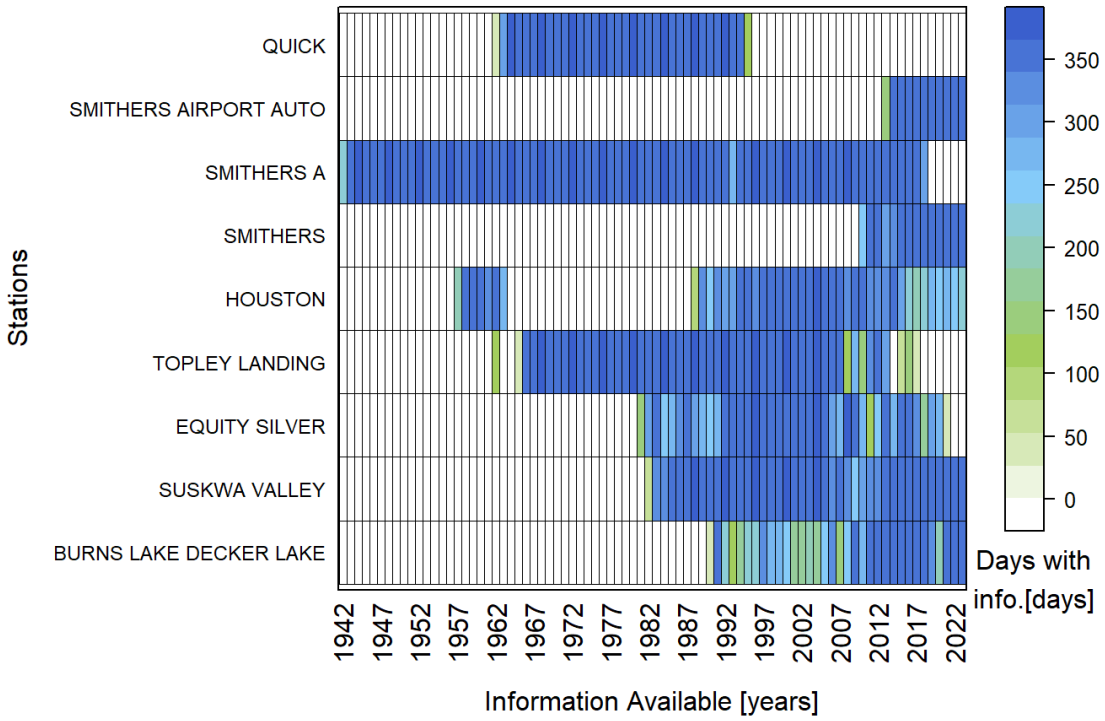
Note: Smithers A and Smithers Airport Auto are located at the same geographic location.

Source: compiled in text from R code \\srk.ad\dfs\na\van\Projects\01_SITES\Telkwa Coal\1CT027.003_2020 EA Water Management\200_Meteorology_Update\Rwork\Telkwa_EA_Temperature_1CT027.003_rev01.html

2.2.3 Missing Data

The meteorological records from the Tenas Deposit Station have low amount of absent records with practicaly 100% of records available for precipitation and air temperature (maximum, minimum, and daily averages). Higher quantity of missing records were found for solar radiation -

mostly during the winter, presumably because of snow cover – and pan evaporation. The missing records and data availability are provided in Figure 2-2 for all measured variables.



Source: compiled from R code SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html

Note: Total data availability is presented after the variable name in parenthesis. Abbreviations have the following measing, ir row-wise order: evap = Pan Evaporation, gust = Wind Gust, prcp = Precipitation, rain = Rainfall, rh = Relative Humidity, snow = Snowfall, snowpack = Snowpack, ssrd = Shortwave Solar Radiation, tavg = Average Daily Temperature, tmax = Maximum Daily Temperature, tmin = Minimum Daily Temperature, ws = Wind Speed.

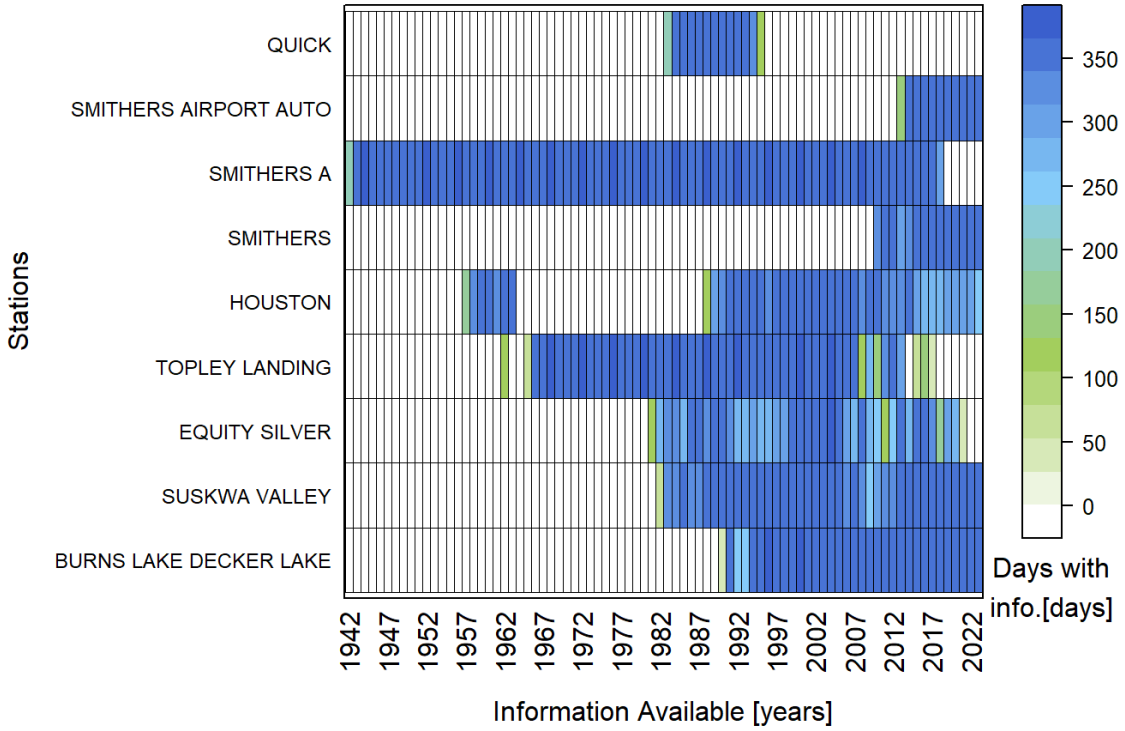


Figure 2-2: Site meteorological records availability

In terms of regional datasets, most stations also present some gaps in their records. Based on the correlations between stations these gaps could be patched appropriately as described in the sections below. Figure 2-3 and Figure 2-4 present the number of days with mean temperature and precipitation records respectively available at each regional station from 1942 to 2023. The color ramp on the right-hand side indicates 0 days of data (white) to a full 366 days (dark blue).

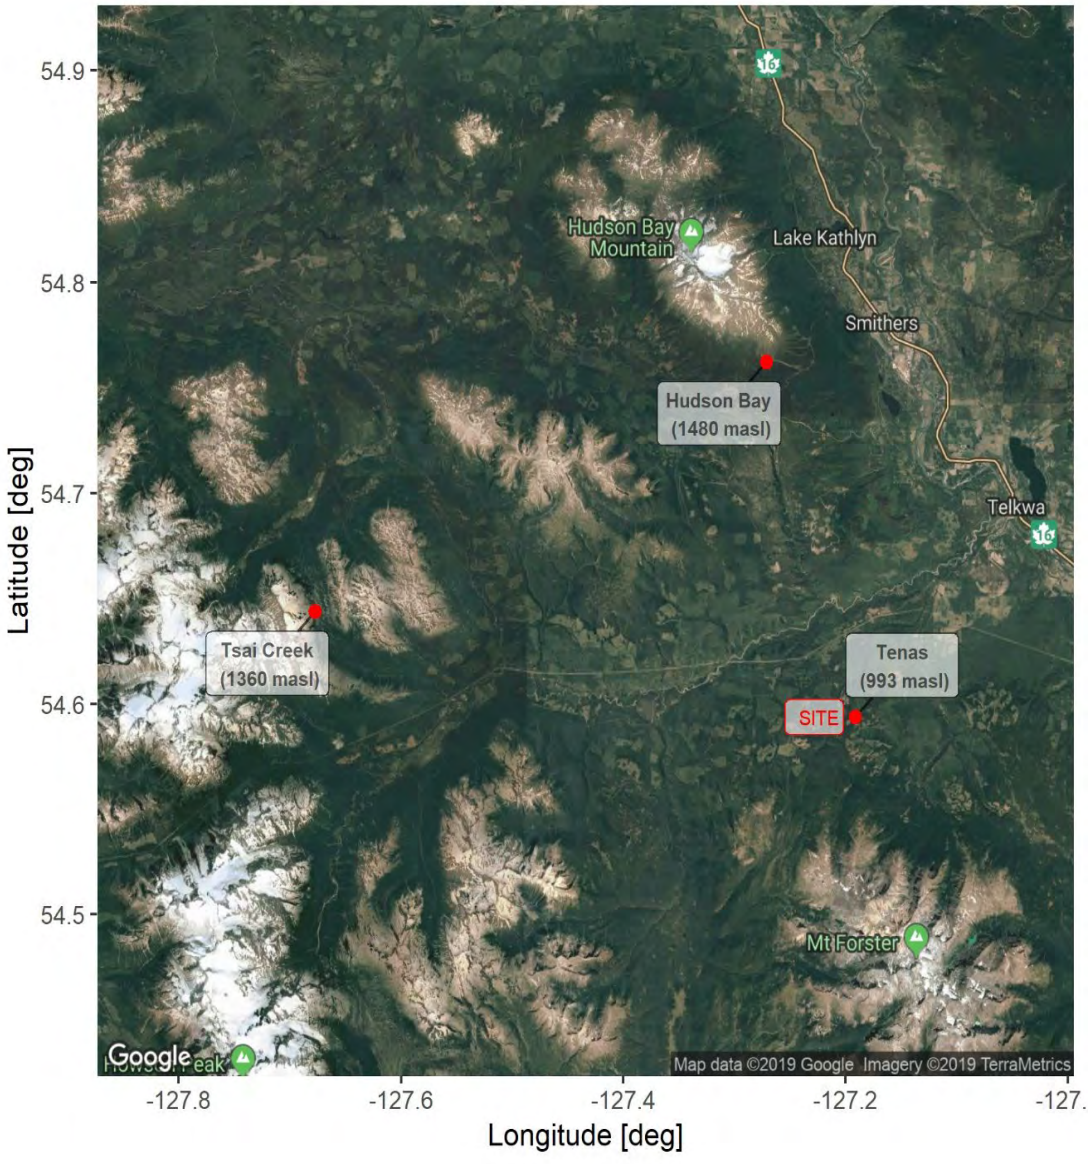
Figure 2-4: Number of Days with Precipitation Data Available Every Year from Regional Stations

2.2.4 Regional Snow Datasets

The British Columbia Snow Survey Data includes datasets from two regional networks:

The Automated Snow Weather Station (ASWS) network is comprised of stations operated by the Ministry of Environment, BC Hydro and others. These stations collect hourly snow water equivalent, snow depth, air temperature, and precipitation. Data is available in near-real-time. Tsai Creek Station is the closest station of this type to the Project and is published by the Ministry of Environment and Climate Change Strategy (MECCS).



The Manual Snow Survey Sites network is operated by the province of British Columbia and manually measures snow depth and snow water equivalent. Measurements are taken monthly when snow is present, providing a record of snowpack across the province. Hudson Bay is the closest manual survey site to the Project. This data is also published by MECCS.

Figure 2-5 illustrates the locations of Tsai Creek and Hudson Bay snow survey stations, and Table 2-2 presents details pertaining to these stations.

Table 2-2: Regional Snow Survey Stations

Station Name	Station Identifier	Latitude [°]	Longitude [°]	Elevation [masl]	Record Start	Record End	Distance from Project [km]
Tsai Creek	4B17P	54.64	-127.68	1360	2003	Current	31.8
Hudson Bay	4B03A	54.76	-127.27	1480	1972	Current	19.4

Figure 2-5: Regional Snow Pillow Stations Hudson Bay and Tsai Creek Shown in Relation to Tenas Deposit Station

2.2.5 Reanalysis Meteorological Datasets

Reanalysis products were used to calculate regional orographic trends for precipitation and temperature. The regional stations could not account for these orographic trends, particularly in winter due to inversions present at some stations, and Project data did not produce a meaningful relationship to regional stations due to its relatively short duration of record.

Climate reanalysis combines gridded global models with observed historical data to produce historical climate and to incorporate adjustments based on developed relationships. Multiple reanalysis datasets are available in different spatiotemporal resolutions. Table 2-3 presents the three reanalysis datasets examined for this study.

Table 2-3: Overview of Reanalysis Datasets Examined in this Study

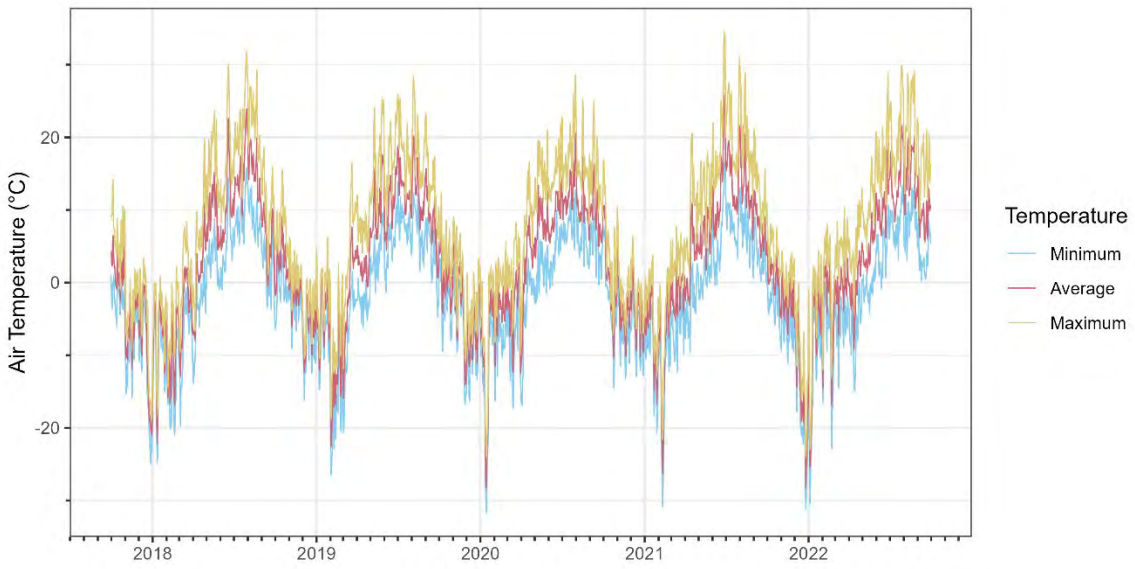
Reanalysis	Institution	Period of Record
ERA-5	European Centre for Medium-Range Weather Forecast (ECMWF)	1979-current
MERRA-2 Modern-Era Retrospective Analysis for research and applications	US National Aeronautics and Space Administration (NASA)	1980- current
PRISM	Pacific Climate Impact Consortium (PCIC)	1950-2007

Source: Compiled in text.

ERA-5 and MERRA-2 are global datasets that provide sub-daily values for multiple meteorological parameters. PRISM is a climate-elevation regression model, used to generate a reanalysis dataset that provides precipitation and maximum and minimum temperature averages on a monthly timestep for the Pacific Region of Canada and the northwestern USA.

2.3 Summary of Available Data

This section presents a summary of the Project Area and regional meteorological datasets.



Meteorological parameters were summarized for the three years of Project data using monthly averages of daily minimum, mean and maximum air temperatures. Monthly average sums of the minimum, mean and maximum total precipitation were calculated. Annual maximum snow water equivalent (SWE) was computed for the Project based on regional snow survey data, transposed to the Project Area.

Other parameters measured at the Tenas Deposit Station include: Wind speed and direction, solar radiation, relative humidity, and barometric/atmospheric pressure. Evaporation rates were calculated based on thes parameters. Measured and calculated parameters are summarized for the Project Area and the long-term regional records in the following sections.

2.3.1 Air Temperature

Project

Temperature is used to estimate snowmelt, evaporation, evapotranspiration, and other inputs such as pond freeze depths. Air temperatures recorded at the Tenas Deposit Station ranged from -31.7°C (January 15, 2020) to 34.5°C (June 27, 2021). Figure 2-6 presents the daily maximum, average and minimum temperature at the Tenas Deposit Station. During the period of record, the coldest month was the month of December 2021 with a mean temperature of -14.0°C, and the hottest month was the month of July 2018 at 15.5°C. The summary of monthly maximum, average and minimum daily temperatures is presented in Table 2-4.

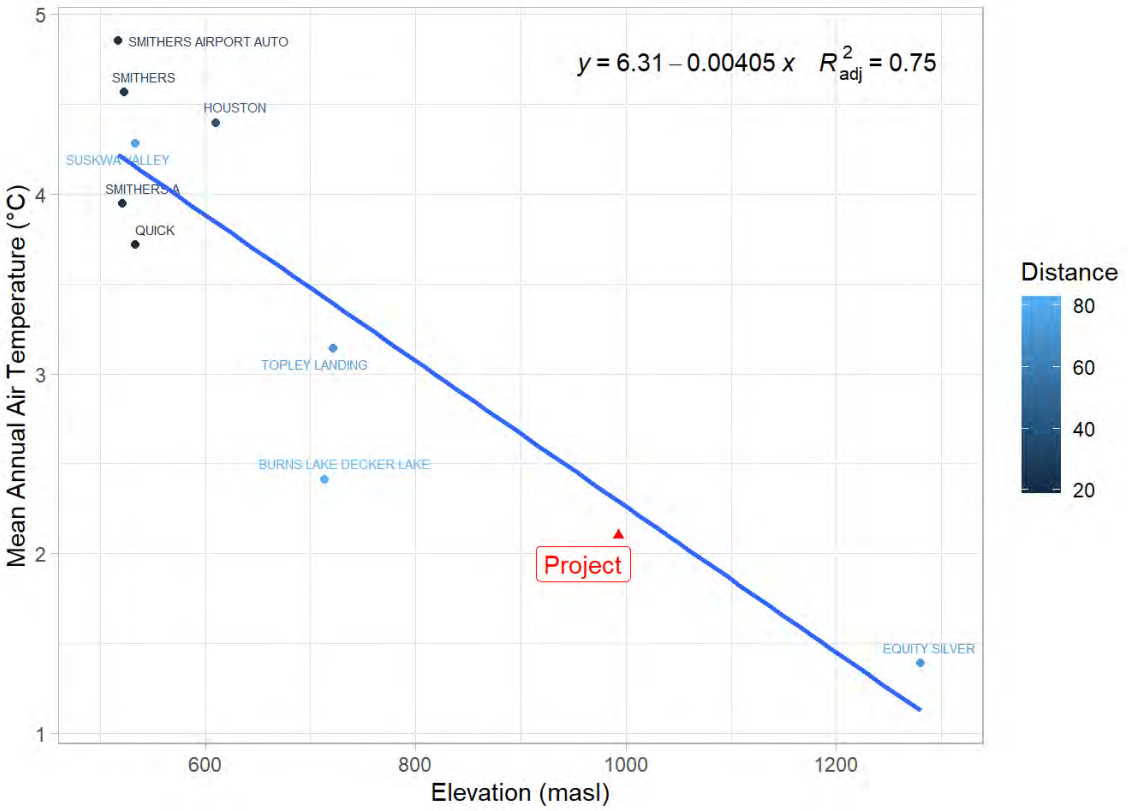
Regional



Temperature records for the Smithers Airport station were extended and patched using data from the Houston station. Figure 2-7 shows the annual distribution of regional temperatures, where the coldest and warmest months are typically January and July, respectively. Regional stations show similar temperature behaviour throughout the year except for Tsai Creek and Equity Silver. These two regional stations appear to show milder winters suggesting a temperature inversion for higher elevations. This suggests monthly correction factors are more appropriate to account for the potential of temperature inversions during the winter months.

Source: \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html

Figure 2-7: Monthly Average Temperatures at Regional Meteorological Stations

Regionally, mean annual temperature decreases with increasing elevation. For a Project site elevation of 993 m (corresponding to the location of the Tenas Deposit Station), the mean annual temperature is approximately 2.5°C colder than temperatures recorded at the Smithers Airport Station (Figure 2-8).

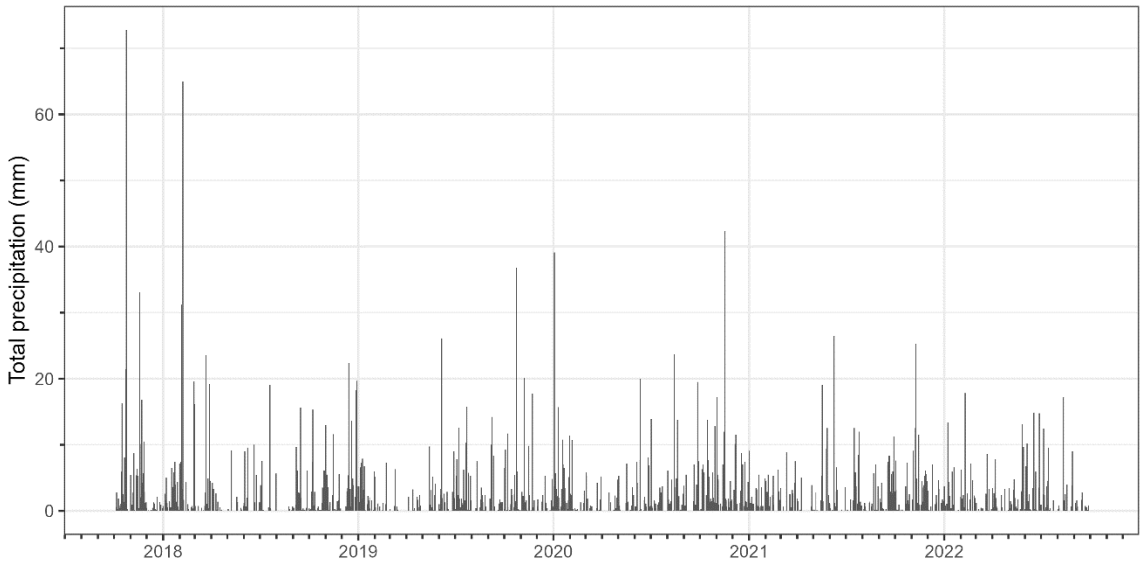

Figure 2-8: Regional Mean Annual Temperature – Elevation Trend

2.3.2 Precipitation

Project

The Tenas Deposit Station recorded from 502 mm to 719 mm in 2018 – 2021. Figure 2-9 presents the recorded daily precipitation from October 2017 to September 2022. The largest single-day precipitation events occurred on 24 October 2017 for rainfall (73 mm) and on 7 February 2018 for snowfall (65 mm). The 24 October 2017 event corresponds to an exceptional runoff event that exceeded historical streamflow records for regional stations in the area (ERM 2019).

The recorded total precipitation at the Tenas Deposit Station (Figure 2-9) was divided into rainfall (mm) and snowfall (mm SWE) components if the Project air temperature record was less than 0 degrees Celsius. Using this estimation, snow ranged from 34% to 71% of total annual precipitation (see Table 2-8 for regional comparison). Monthly cumulative values of measured total precipitation and estimated rainfall and snowfall are summarized in Table 2-5.

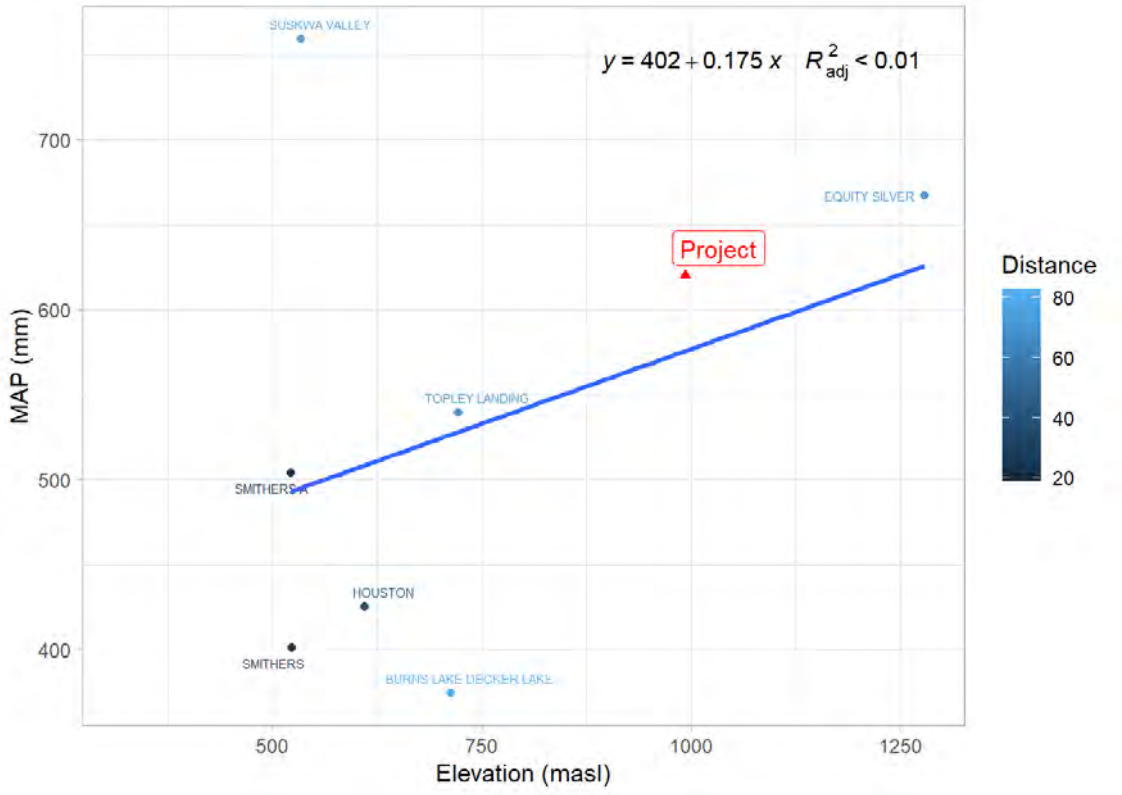
Regional

A regional precipitation analysis was carried out to identify trends and elevation correlations. The Smithers Airport Auto and Smithers A stations (10775001 and 1077500) were merged to generate a long-term record. Remaining gaps in this record were patched with Quick as well as ERA-5, using quantile mapping methods. The resulting patched Smithers A record provides 73 years of complete data.

Average yearly precipitation, rainfall and snowfall for regional stations are presented in Table 2-6 for their corresponding period of record. Regional stations present varying mean annual precipitation (MAP) in the range of 415 mm to 760 mm with precipitation occurring mainly as rainfall except for Equity Silver where almost half of the precipitation falls as snow due to its higher elevation.

Table 2-6: Regional Stations Annual Precipitation, Rain, Snow and Corresponding Proportions

Station	Mean Annual Precipitation [mm]	Mean Annual Rainfall [mm]	Mean Annual Rainfall [%]	Mean Annual Snowfall [SWE mm]	Mean Annual Snowfall [%]
SMITHERS A (patched)	511	344	67%	166	33%
QUICK	469	308	66%	161	34%
HOUSTON	425	293	69%	132	31%
TOPLEY LANDING	539	310	58%	229	42%
EQUITY SILVER	661	348	53%	314	47%
SUSKWA VALLEY	756	552	73%	204	27%
BURNS LAKE DECKER LAKE	415	249	60%	166	40%



Notes:

1. Rainfall and snowfall proportions as percentages of the mean annual precipitation.
2. Smithers A patched with Smithers Airport Auto, Quick and ERA-5.
3. Mean annual values calculated based only on years with snow and rain measurements

Source: compiled in text from R code \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html and Canadian Climate Normals https://climate.weather.gc.ca/climate_normals/index_e.html

Figure 2-10 illustrates the regional correlation between MAP and elevation. A negative value for the determination coefficient (R^2 presented in Figure 2-10) indicates the correlation between elevation and MAP using only the regional meteorological datasets is poor.

The relationship between MAP and elevation is likely less significant at this location due to the more dominant effects of topography and the Pacific Ocean as a moisture source. The west-east gradient and proximity to mountain range with rain shadow effects are the most important factors affecting precipitation in this area. Orographic gradients were further evaluated using Reanalysis datasets and are discussed in Section 4.1.2.

Note: Quick station data not included due to differing timelines
