FINAL

Technical Memo

March 3, 2022

To	Dan Farmer, P.Eng., Allegiance Coal Limited
From	Kyle Scale, P.Eng., Ph.D.; Calvin Boese, P.Eng., M.Sc.
Subject	Liner Design and Construction Methodology for Tenas Management Ponds
Client	Telkwa Coal Ltd.
Project	2CT025.008.0300

1 Introduction

Telkwa Coal Ltd. (TCL) has retained SRK Consulting (Canada) Inc. (SRK) to design and provide a preliminary construction methodology for a liner system that will reduce seepage rates from the Tenas Management Ponds to below allowable thresholds defined in SRK's site water balance (SRK, 2020a). This liner assessment was initially conducted on four liner alternatives in the preliminary seepage assessment (Section 4.4.1); however, based on the performance and estimated costs, one of these liner alternatives was advanced to a focused seepage assessment (Section 4.4.2). The construction methodology for the selected liner alternative is detailed in Section 0 at an early design stage level.

This technical memo is divided into sections describing the Liner Design, Seepage Modeling, Construction Methodology, and Recommendations. The *Liner Design* section provides background on the seepage design criteria from SRK's site water balance, geometry of the PAG management ponds, and details the liner materials and liner system configurations. The *Seepage Modeling* section details the cross sections that serve as a basis for the seepage models, the assumptions and calibration of these models, and presents the results of the seepage assessment and presents a recommended liner option. The *Construction Methodology* section outlines the assumptions, material characteristics, execution of the liner system at an early design stage level, and quality control. The technical memo concludes with the *Recommendations* section, presenting SRK's recommendations for field and laboratory testing, construction methodology, and quality control of the recommended liner system.

2 Background

The Tenas Project is in central British Columbia, approximately 15 km south of Smithers and 2 km southwest of Telkwa. The Project site is located south of the Tenas River and the boundaries of the Project encompass the lower reaches of the Telkwa River, Goathorn Creek, and Pine Creek. The Tenas Project's total mine life is anticipated to be 22 years, including one year of pre-stripping and construction followed by 21 years of production. The mine plan was designed and scheduled in a manner that allows potentially-acid generating (PAG) rock to be deposited into management ponds (MP), including the East Management Pond (EMP), West Management Pond (WMP), and North Management Pond (NMP). These MP are above-ground PAG rock storage facilitates. The WMP consists of a portion that is an excavated pit (*Tenas Pit Phase 9*), referred to herein as '*In Pit*', and the remaining portion outside the pit referred to herein as '*Ex Pit*'.

Environmental containment is to be achieved with liner systems that are constructed along the bottom of the ponds and the upstream slopes of the perimeter dams.

3 Liner Design Basis

The following subsections describe the seepage design criteria, pond geometry, material properties, and liner configurations.

3.1 Seepage Design Criteria

A preliminary water balance provided design targets for the liner seepage analyses that evaluated seepage rates through the bottom of the MP and upstream slopes of the perimeter dams. The maximum allowable seepage through the MP catchments was determined to be 2,800 m^3/day from the site wide water balance (SRK, 2020a). This value represents the maximum seepage rate allowed to maintain a positive water balance over the PAG rock (e.g. maintain a minimum 1 m capping of ponded water).

This value is conservatively based on the "*10 Year Dry*" scenario. For the average year scenario, the allowable seepage rate through the management pond catchments increases to 4,260 m^3/day. For reference, the water quality target from the Definitive Feasibility Study (DFS) model was 1,700 m^3/day.

3.2 Pond Geometry and Potential Seepage Areas

Design elevations for the dam crests, freeboard, and areas pertinent to the seepage assessments are included in Table 1. Design revision 1 includes added capacity to account for the reduction in MP storage capacity due to the incorporation of a 1 m thick soil over-liner as the liner protective component (discussed in Section 4.4.2). This revision included raising the dam crests and freeboard elevations for the EMP, NMP, and WMP (Ex-Pit).

Table 1: Model Geometry for the TCL Management Ponds

Design Revision	Management Pond	Area Pond[1] (m^2)	Area Upstream Dam Slopes[1] (m^2)	Cumulative Area[1] (m^2)	Dam Crest Elev. (masl)	Freeboard Elev. (masl)
0	EMP	901,000	163,000	1,064,000	850	849
	WMP (Ex Pit)	371,600	122,000	493,600	850	849
	WMP (In Pit)	440,400	n/a	440,400	n/a	n/a
	NMP	76,900	184,500	261,400	830	829
1	EMP	961,939	180,136	1,142,075	852	851
	WMP (Ex Pit)	361,874	141,148	503,022	852	851
	WMP (In Pit)	533,548	n/a	533,548	n/a	n/a
	NMP	210,190	83,017	293,207	831	830

Notes:
(1) MP surfaces areas contributing to seepage through the liner system.
(2) Model geometry for Design Revision 1 provided by Telkwa on November 17, 2020.

3.3 Material Properties

Table 2 lists the materials that were modeled in the seepage assessment for the various liner design options. The high case for the native soils represents an increase of the base case hydraulic conductivities by a factor of 2.7 (SRK, 2020b).

Table 2: Materials Considered for the Liner Seepage Assessment

Material	Hydraulic Conductivity, k (m/s)	
	Base Case	High Case
Native soil (EMP)[1]	3.0E-6	8.1E-6
Native soil (NMP)[1]	1.9E-6	5.1E-6
Bentonite[2]	5.0E-11	-
Soil-bentonite mixture[2]	1.0E-9	-
Soil-bentonite mixture (optimized)[2]	1.0E-10	-
Skilhorn clay[3]	5.9E-9	-
Clay-bentonite mixture[2]	8.6E-10	-
Skeena Sedimentary Rock[4]	3.62E-7	-

Notes:
(1) Values for native soil derived from calibration with the site wide FEFLOW® groundwater model.
(2) Values for bentonite, soil-bentonite mixtures, and clay-bentonite mixtures assumed based on experience with previous projects.
(3) Values for Skilhorn measured in laboratory falling head hydraulic conductivity testing performed with a flexible wall permeameter.
(4) Values for Skeena sedimentary rock (bedrock) obtained from FEFLOW® groundwater model.

A hydraulic conductivity of 1.0E-9 m/s for the soil-bentonite mixture was calculated for a 5% (by volume) soil-bentonite mixture based an assumed hydraulic conductivity for bentonite of 5E-11 m/s. However, recent laboratory testing performed by Golder Associates on available bentonite are showing the hydraulic conductivity to be 3E-12 m/s. The calculated hydraulic conductivity of the soil-bentonite mixture, using the recent lab test value, equates to 6E-11 m/s. Based on the lab data and previous experience with a similar northern project, it is anticipated that a hydraulic conductivity value of 1E-10 m/s can be achieved and was therefore considered in the liner option assessment as an optimized value.

4 Seepage Model Development

Two-dimensional liner seepage analyses were carried out with GeoStudio's SEEP/W modeling software (Version 11.0.1.21429). The following subsections detail the cross-sections, model assumptions and calibration, and results of the seepage assessment.

4.1 Cross Sections

The cross sections shown in Figure 1 were developed into seepage models for the NMP, EMP, and WMP based on site topography, bedrock elevations, and perimeter dam designs. These cross sections were chosen along alignments that intersect the lowest topography in each pond as well as nearby creeks (*topographic lows*). Section 1 (1'-1') was used to develop the model for the NMP; Section 2 (2'-2') was used to develop the model for the EMP; and Sections 3 (3'-3') and 4 (4'-4') were used to develop models for the WMP.

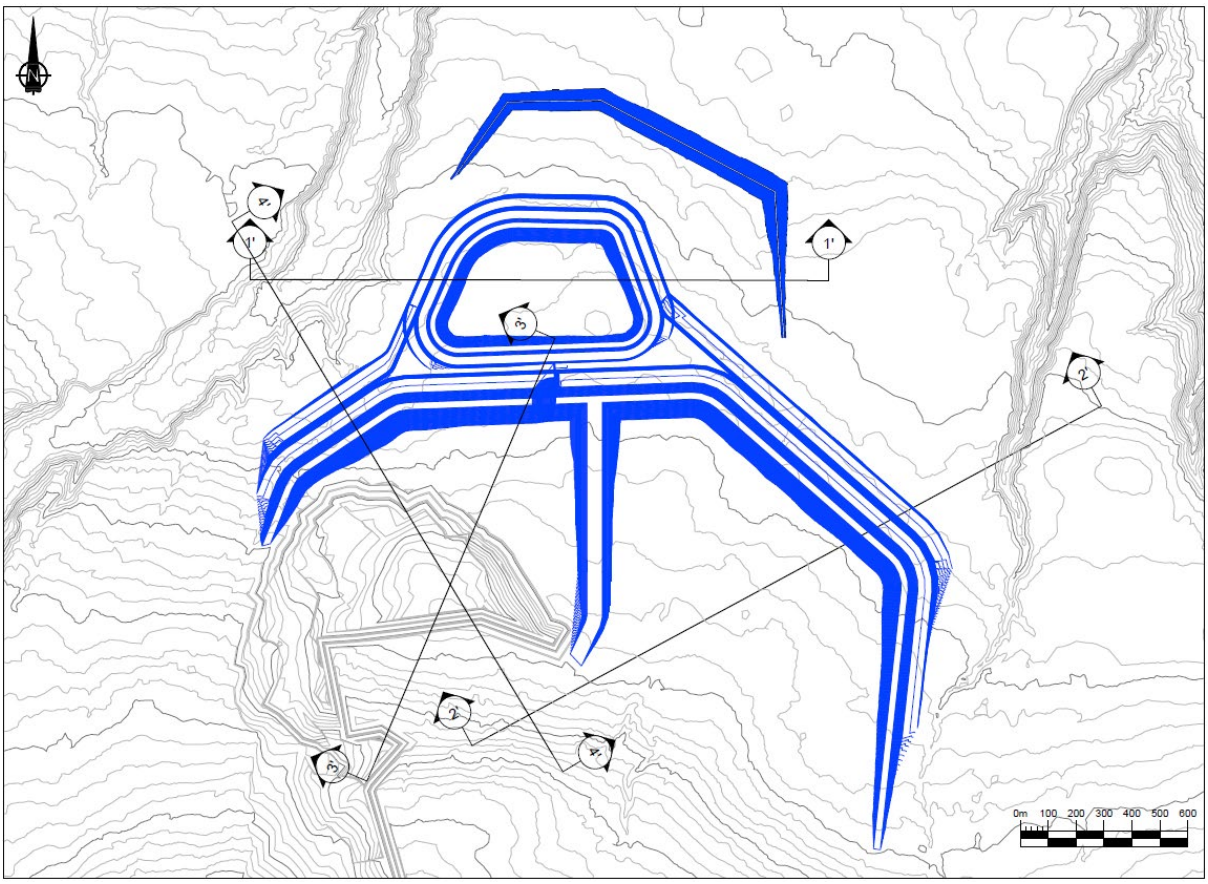

Figure 1: Cross sections of the North Management Pond (Section 1'-1'), the East Management Pond (Section 2'-2'), and the West Management Pond (Sections 3'-3' and 4'-4') that served as the basis for the seepage models

4.2 Model Assumptions

The seepage models for the EMP, WMP, and NMP were developed based on cross sections that included the site topography, bedrock elevations, and designs of the perimeter dams. For the preliminary seepage assessment only Section 1 for the NMP and Section 2 for the EMP were evaluated. At this early stage, seepage through the WMP was assumed to be equivalent to seepage through the EMP.

The seepage assessment for revision 1 included two additional sections for the WMP that spanned the *In Pit* and *Ex Pit* portions. Seepage through unlined portions of the WMP *In Pit* were determined using FEFLOW® groundwater modeling software by applying a total head of 851 masl (*the dam freeboard elevation*). The WMP *In Pit* portion is assumed to be graded at 2.5H:1V from the *Ex Pit* portion towards the south-southwest. This produces a portion of the north slope that is comprised of overburden and a portion that is a bedrock pit wall. The sub-vertical bedrock cliff at the south of the model is unlined in Model Scenarios 1 to 8 and is re-sloped to 2.5H:1V and lined in Scenarios 9 to 16. These scenarios are discussed in Section 4.4.

Seepage models developed for the preliminary and revision 1 seepage assessments consider the uppermost soil layer to be unsaturated and the underlying soil (below the estimated water table) to be saturated.

4.3 Calibration

The site wide groundwater model was developed with FEFLOW® groundwater modeling software. This model utilized data from recent and historic drilling campaigns to distribute the native ground in the vicinity of the MP into *Silty Clay* and *Sand & Gravel*, with hydraulic conductivities of 2E-7 and 3E-6 m/s, respectively. These materials were used as a basis to calibrate the two-dimensional liner seepage models.

To accomplish this calibration, the hydraulic conductivity of the materials in the unlined two-dimensional seepage models were toggled until the seepage rates matched the rates measured with FEFLOW®. For the purposes of this calibration, the resulting material at the EMP and WMP were *Sand & Gravel*, with a hydraulic conductivity of 3E-6 m/s, and the material at the NMP was 40% *Clay* and 60% *Sand & Gravel,* with a hydraulic conductivity of 1.88E-6 m/s.

4.4 Liner Configurations

Four liner configurations were modeled as part of the preliminary seepage assessment (Design Revision 0) and one of these configurations was advanced to the focused seepage assessment (Design Revision 1).

4.4.1 Preliminary Seepage Assessment (Design Revision 0)

The liner options that were modeled in the two-dimensional SEEP/W (2020) for the preliminary seepage assessment are listed below:

1. Native soil with bentonite disked into the surface at 0.15 or 0.30 m.
2. Clay from Skilhorn Quarry placed to a depth of 1 to 2 m.
3. Clay from Skilhorn Quarry placed to a depth of 1 m with bentonite disked to a depth of 0.15 or 0.30 m.
4. Bentonite placed to a thickness of 0.15 or 0.30 m and covered with a minimum 0.15 m of native soil.

4.4.2 Focused Seepage Assessment 1 (Design Revision 1)

The soil-bentonite liner system (Option 1 from Design Revision 0) was progressed to a focused liner seepage assessment in 0.15 m, 0.30 m, 0.45 m, and 0.56 m thicknesses with the optimized bentonite hydraulic conductivity of 1E-10 m/s. Table 3**Error! Reference source not found.** presents the various configurations of the soil-bentonite liner system that were assessed.

Each configuration considers the WMP *Ex Pit* portion to be lined. Configurations 1 to 8 consider the overburden pit slope of the WMP *In Pit* portion to be lined. Configurations 9 to 16 consider the subvertical bedrock cliff to be re-sloped to 2.5H:1V. These configurations were modeled with the base and high case hydraulic conductivity values listed in Table 2.

Table 3: Soil-Bentonite Liner Systems Assessed as Part of the Focused Seepage Modeling

Configuration	Case	SB Thickness (m)	NMP	EMP	WMP Liner Configurations		
					OVB Slope Liner	In-Pit Liner	BR Pit Wall Resloped
1	BC	0.15	Y	Y	Y	N	N
2	BC	0.30	Y	Y	Y	N	N
3	BC	0.45	Y	Y	Y	N	N
4	BC	0.56	Y	Y	Y	N	N
5	HC	0.15	Y	Y	Y	N	N
6	HC	0.30	Y	Y	Y	N	N
7	HC	0.45	Y	Y	Y	Y	N
8	HC	0.56	Y	Y	Y	Y	N
9	BC	0.15	Y	Y	Y	Y	N
10	BC	0.30	Y	Y	Y	Y	N
11	BC	0.45	Y	Y	Y	Y	N
12	BC	0.56	Y	Y	Y	Y	N
13	HC	0.15	Y	Y	Y	Y	Y
14	HC	0.30	Y	Y	Y	Y	Y
15	HC	0.45	Y	Y	Y	Y	Y
16	HC	0.56	Y	Y	Y	Y	Y

Notes:
(1) BC = Base Case; HC = High Case; MP = Management Pond; BR = Bedrock; OVB = Overburden; SB = Soil-Bentonite.
(2) For the High Case, the hydraulic conductivity of the underlying soils has been increased by a factor of 2.7.
(3) The Soil-Bentonite material assumes an optimized hydraulic conductivity of 1E-10 m/s.

5 Seepage Model Results

Seepage rates were quantified through the surface areas corresponding to the upstream perimeter dam slopes and MP pond bottoms. Results of the preliminary seepage modeling (Design Revision 0) are presented in Section 5.1 and results of the focused seepage modeling (Design Revision 1) are presented in Section 5.2.

5.1 Results of the Preliminary Seepage Modeling (Design Revision 0)

Preliminary seepage modeling was conducted with the geometry shown in Table 1 for *Design Revision 0.* Only Section 1 for the NMP and Section 2 for the EMP were modeled at this stage and the *In Pit* portion of the WMP was not independently assessed. Based on FEFLOW® groundwater modeling, with a scenario considering a 0.5 m thick compacted clay liner, the seepage from the *Ex Pit* portion of the WMP would be 483 m^3/day. This seepage rate was factored into the seepage results calculated for the various liner systems with SEEP/W (2020).

Results of the two-dimensional liner seepage assessment are shown in Table 4 and plotted in Figure 2. Seven liner alternatives provided a seepage rate < 2,800 m^3/day, which corresponds to the maximum allowable seepage rate for the *10 Year Dry* scenario. Four of these alternatives barely met the design criteria. However, the design criteria was easily achieved for bentonite placed to a thickness of 0.15 or 0.30 m covered with a minimum 0.15 m of native soil, and the optimized native soil with bentonite disked into the surface at 0.15 m (soil-bentonite). Each of the liner alternatives listed below provide a seepage rate ≤ 4,260 m^3/day, which corresponds to the *Average Year* scenario.

Table 4: Results from the Two-dimensional Liner Seepage Assessment for the Various Liner Configurations Modeled in SEEP/W

Model	Seepage (m^3/day)	Seepage < 2800 m^3/day (Y/N)
No Liner	6,992	N
0.15m Soil-Bentonite	3,226	N
0.15m Soil-Bentonite (Optimized)	1,606	Y
0.3m Soil-Bentonite	2,779	Y
1m Skilhorn Clay	3,201	N
2m Skilhorn Clay	2,779	Y
1m Skilhorn Clay + 0.15m Clay-Bentonite	2,788	Y
1m Skilhorn Clay + 0.30m Clay-Bentonite	2,580	Y
0.15m Bentonite	1,204	Y
0.30m Bentonite	843	Y

Notes:
(1) Seepage limit based on the 10 Year Dry scenario developed in the site water balance is 2,800 m^3/day.
(2) Seepage limit based on the Average Year scenario developed in the site water balance is 4,260 m^3/day.

Results of the two-dimensional liner seepage assessment are plotted in Figure 2.

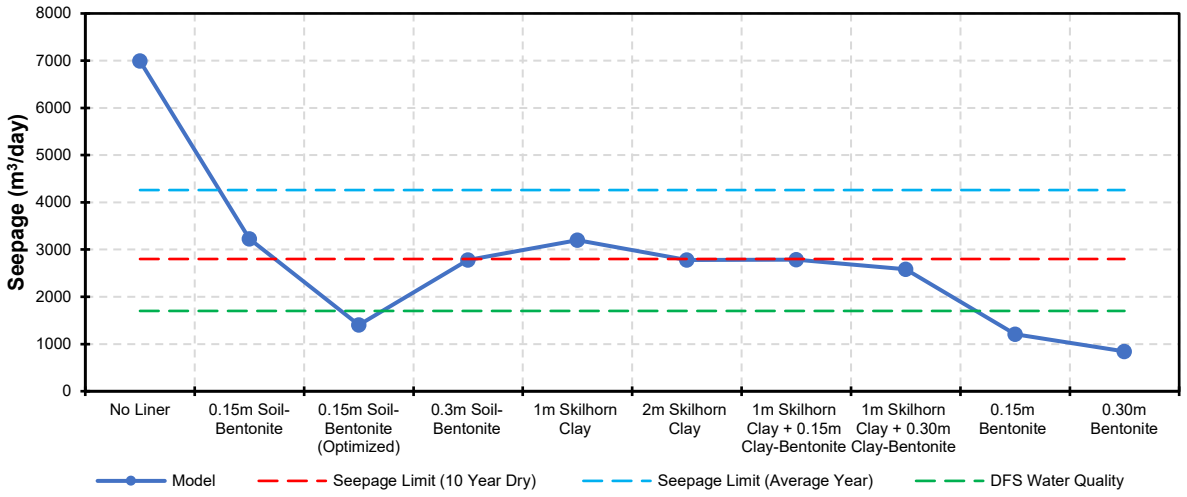

Figure 2: Results of the Preliminary Liner Seepage Assessment (Design Revision 0) for the Various Liner Configurations Modeled in SEEP/W

From these scenarios, the 0.15 m soil-bentonite liner system with the optimized bentonite hydraulic conductivity of 1E-10 m/s was advanced to the focused seepage modeling (Design Revision 1). The alternatives for the 0.15 m and 0.30 m pure bentonite were not advanced due to the costs being significantly higher compared to the other liner systems.

5.2 Results of the Focused Seepage Modeling (Design Revision 1)

The 0.15 m soil-bentonite liner system with the optimized bentonite hydraulic conductivity of 1E-10 m/s was subjected to a more detailed assessment as part of the focused seepage modeling (Design Revision 1). Additional 0.30 m, 0.45 m, and 0.56 m soil-bentonite liner systems with the optimized bentonite hydraulic conductivity of 1E-10 m/s were also incorporated into the focused seepage modeling. These seepage models were developed with the geometry shown in Table 1 for *Design Revision 1*.

5.2.1 WMP Liner Assessment

For the focused seepage modeling, two cross sections were modeled for the WMP (Section 3 and Section 4), in addition to the sections for the NMP and EMP. The new cross sections spanned the WMP *In Pit* and *Ex Pit* portions.

The results of the focused seepage assessment for all MPs with the geometry shown in Table 1 for *Design Revision 1* are listed in Table 5 and shown in Figure 3. The seepage rates for the WMP *In Pit* and *Ex Pit* portions are the average of Sections 3 and 4. As noted in Section 4.4.2, Configurations 1 to 8 consider the overburden pit slope of the WMP *In Pit* portion to be lined. Configurations 9 to 16 consider the subvertical bedrock cliff to be re-sloped to 2.5H:1V.

Table 5: Results of the Focused Liner Seepage Assessment for the NMP, EMP, and WMP *In Pit* and *Ex Pit* Conducted using the Geometry from Design Revision 1

Liner	Case	SB Thickness (m)	WMP Liner Configurations			Seepage Rates (m^3/day)				
			OVB Slope Liner	In-Pit Liner	BR Pit Wall Slope Liner	EMP	NMP	WMP (In-Pit)	WMP (Ex-Pit)	Cumulative
1	BC	0.15	Y	N	N	738	296	591	706	2331
2	BC	0.30	Y	N	N	458	161	665	384	1667
3	BC	0.45	Y	N	N	334	109	710	267	1419
4	BC	0.56	Y	N	N	277	87	720	215	1299
5	HC	0.15	Y	N	N	978	320	1346	764	3408
6	HC	0.30	Y	N	N	536	164	1395	397	2492
7	HC	0.45	Y	N	N	366	112	1429	277	2184
8	HC	0.56	Y	N	N	296	90	1436	223	2044
9	BC	0.15	Y	Y	Y	738	296	234	748	2017
10	BC	0.30	Y	Y	Y	458	161	197	392	1207
11	BC	0.45	Y	Y	Y	334	109	179	269	891
12	BC	0.56	Y	Y	Y	277	87	186	216	766
13	HC	0.15	Y	Y	Y	978	320	384	759	2441
14	HC	0.30	Y	Y	Y	536	164	273	385	1358
15	HC	0.45	Y	Y	Y	366	112	226	265	969
16	HC	0.56	Y	Y	Y	296	90	226	216	827

Notes:
(1) BC = Base Case; HC = High Case; MP = Management Pond; BR = Bedrock; OVB = Overburden; SB = Soil-Bentonite
(2) For the High Case, the hydraulic conductivity of the underlying soils has been increased by a factor of 2.7.
(3) The Soil-Bentonite material assumes an optimized hydraulic conductivity of 1E-10 m/s.

The results of the focused seepage assessment for all MPs with the geometry shown in Table 1 for *Design Revision 1* are shown in Figure 3.

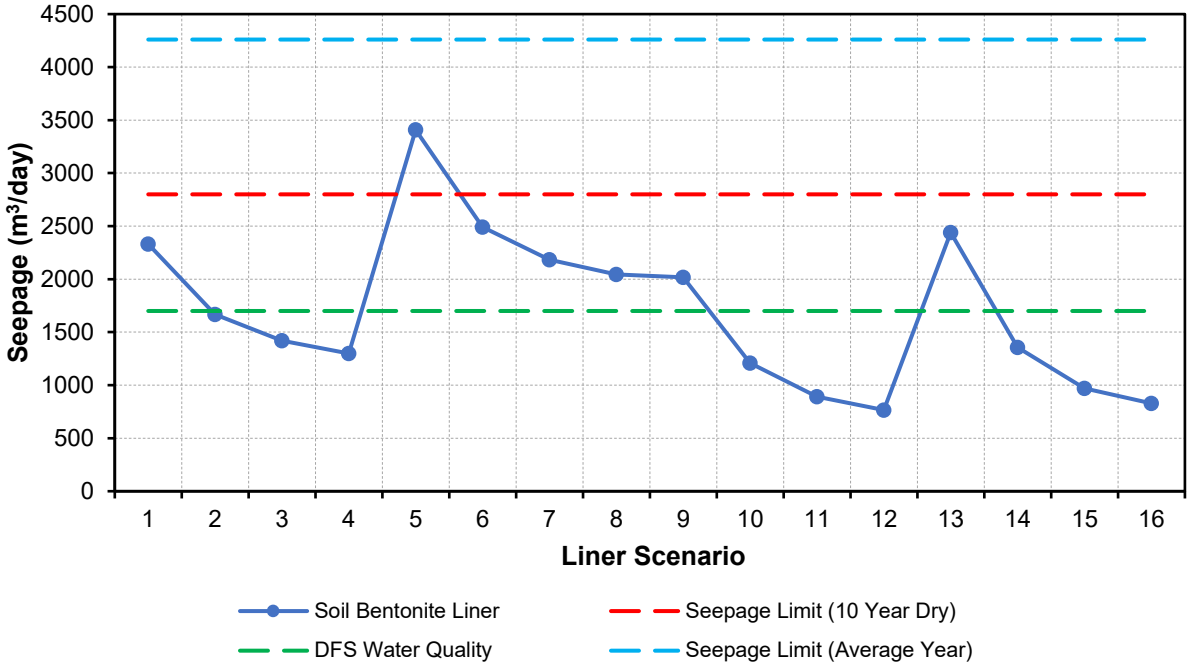

Figure 3: Results of the Focused Liner Seepage Assessment (Design Revision 1) for the Various Soil-bentonite Liner Configurations Modeled in SEEP/W

Each of the liner alternatives listed above provide a seepage rate ≤ 4,260 m^3/day, which corresponds to the *Average Year* scenario. The 0.3 m, 0.45 m, and 0.56 m soil-bentonite liner systems provide seepage rates < 2,800 m^3/day for both the base and high cases, which corresponds to the maximum allowable seepage rate for the *10 Year Dry* scenario.

5.3 Recommended Liner Design

The recommended liner design is the 0.45 m soil-bentonite liner constructed in the NMP, EMP and over the *Ex Pit* portion of and the overburden pit slope of the WMP. This liner system provides a seepage rate ≤ 2,800 m^3/day for both the base and high cases, which corresponds to the maximum allowable seepage rate for the *10 Year Dry* scenario.

6 Construction Methodology

The following section details a preliminary construction methodology for the recommended 0.45 m soil-bentonite liner system that will be constructed in three 0.15 m lifts. This construction methodology was completed at an early design stage level and will be refined in greater detail in detailed design engineering.

6.1 Assumptions

It is assumed that construction of the embankments and buttresses are to be completed to the specifications in SRK (2021).

Table 6 lists the lined areas for the various MP that were evaluated in the preliminary cost estimate.

Table 6: Lined Areas for the Various Liner Alternatives

Design Revision[1]	Management Pond	Area Pond (m^2)	Area Upstream Dam Slopes (m^2)	Cumulative Area (m^2)
1	EMP	961,939	180,136	1,142,075
	WMP[2] (Ex Pit)	361,874	141,148	503,022
	NMP	210,190	83,017	293,207

Notes:
(1) Model geometry for Design Revision 1 provided by Telkwa on November 17, 2020.
(2) Lining of the WMP *In Pit* portion is not being considered for the construction methodology

Plan view of the areas requiring soil-bentonite liner is shown in Figure 4.

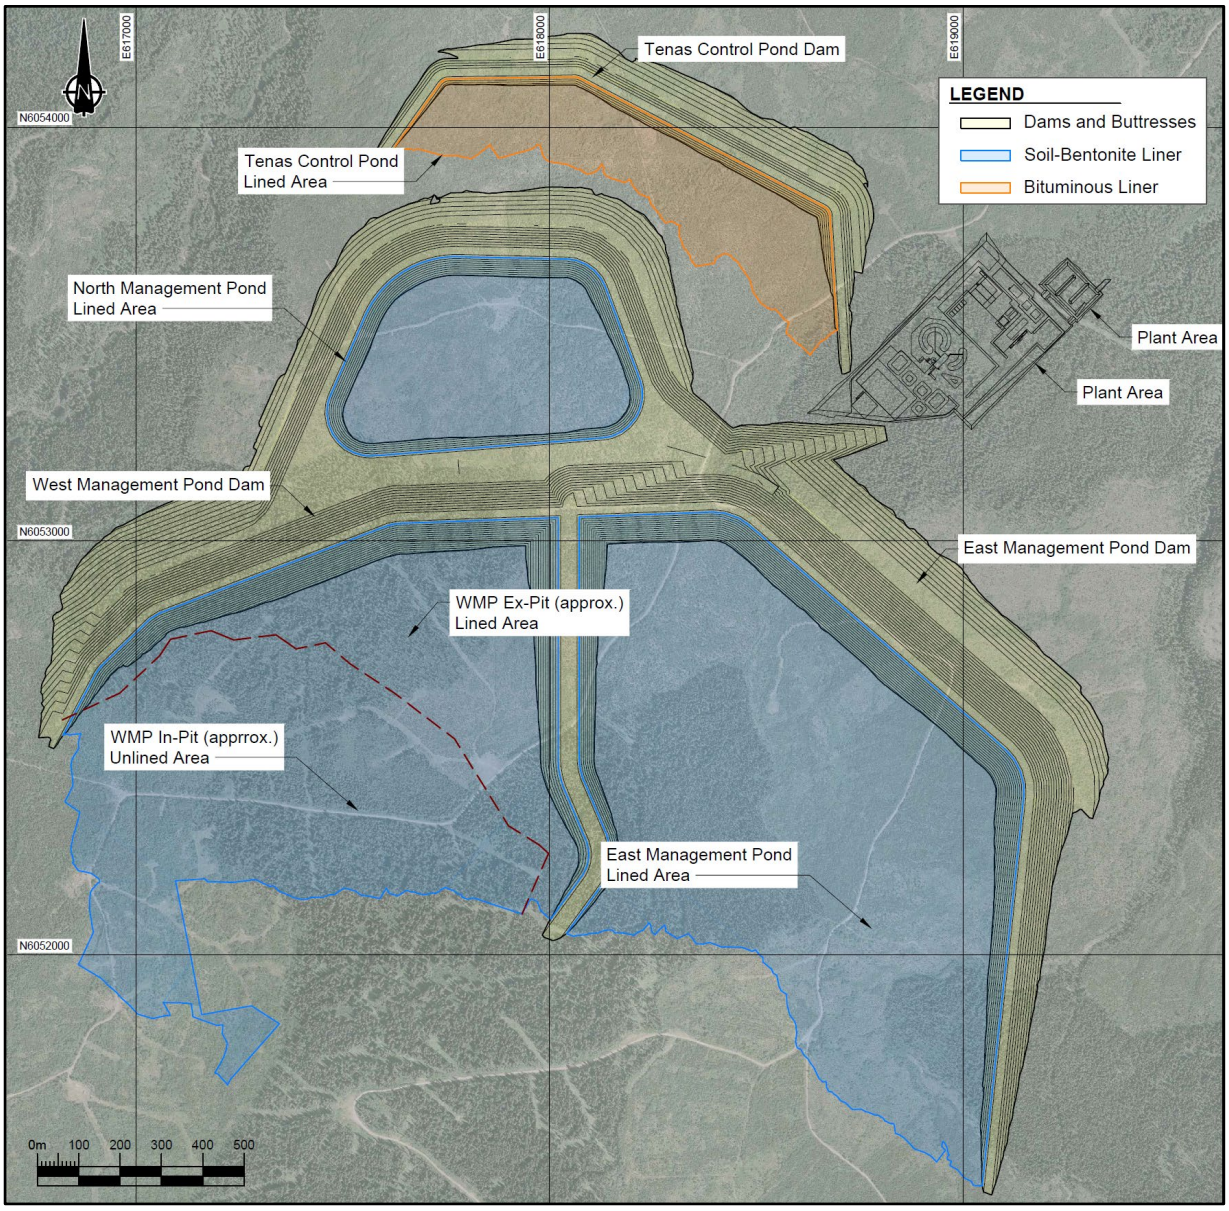

Figure 4: Plan view of the lined surface areas of the Tenas Control Pond and PAG management ponds at the Tenas Project

6.2 Material Characteristics

The blend of materials used for the soil-bentonite liner system (surface soils and bentonite) depend on the parameters adopted in the design, specifically the geotechnical parameters and hydraulic conductivity. The material characteristics and its adequacy to quality standards will need to be proven in laboratory testing and in the field.

Field obtained geotechnical parameters should be equal to or better than those adopted in the design. The *in-situ* hydraulic conductivity of the soil-bentonite liner should have a hydraulic conductivity ≤ $1x10^{-10}$ m/s; therefore, a correct characterization of the geotechnical parameters (particle-size distribution and clay/bentonite content) and parameters associated with the condition of permeability (degree of compaction, *in-situ* hydraulic conductivity) will be required. Additional characteristic parameters are recommended to be evaluated during the construction works to check compliance with minimum material requirements during construction.

6.2.1 On-Site Soil

The selected area for the MP is located at the north and north-east of the projected Tenas open pit. The overburden material is composed principally of a very stiff to hard lean clay (CL), with low to medium plasticity, with intervals of high plasticity clay (CH), clayey silty sand (SC or SM) or gravel (GC or GM) at various depths (with an overburden total thickness equal or higher than 30 m in most of the extension).

Fine-grained and coarse-grained native soil utilized for the soil-bentonite liner system will be exposed during foundation preparation (described in Section 6.3.3). Coarser-grained granular particles such as cobbles and boulders should be removed. The native soil should be subjected to field and laboratory testing to verify the proportion of bentonite required to meet the target hydraulic conductivity ≤ $1x10^{-10}$ m/s, which served as the basis of the liner design.

6.3 Execution of the Liner System

6.3.1 General

During the construction procedure (cleaning, excavation, embankment construction and operations), additional information related to foundation characteristics and slope materials can be obtained. This information can continue to inform and help to develop processes.

6.3.2 Equipment

Equipment options that can be considered for construction of the soil-bentonite liner system include haul trucks, haul trucks equipped with truck mounted spreaders or tractors pulling trailer mounted spreaders, smooth-drum and/or padfoot vibrating compactors, tractors (equipped with or) pulling trailer mounted rotovators or disc harrows, dozers, or graders. The most suitable equipment will be selected by Telkwa Coal based on the soil characteristics and construction requirements.

6.3.3 Foundation Preparation

In preparation for construction of the soil-bentonite liner system, clearing and grubbing should be completed until surface soils, trunks, roots, and topsoil materials have been removed and no appreciable content of organic matter remains:

- Clearing involves cutting of tree stumps and brush, and removal of snow and ice.
- Grubbing involves removal of tree stumps, shrubs, grasses, including their complete root system.

The terrain slope should be uniform for consistent pre-disking and subsequent application & mixing of bentonite.

6.3.4 Placement, Disking, and Compaction

In this section, preliminary placement, disking, and compaction specifications are provided. These will be further studied and updated during detailed design engineering.

Previous Studies

Placement, discing, and compaction equipment and use shall be determined from field studies in trial pads. From these studies, the optimum combination of type of equipment and operation shall be specified. The feasibility of pre-disking the upstream dam surface area shall be assessed on a trial embankment. However, it may be determined that instead of pre-disking, the upstream dam face should be scarified with a toothed excavator bucket or alternative methods.

Pre-Disking

Construction of the soil-bentonite liner system involves pre-disking the uppermost 0.15 m of soil to ensure hydraulic connectivity of the native soils and bentonite. This will take place following inspection and approval of preliminary foundation preparation (clearing and grubbing). The field engineer shall carry out visual inspection and approval of the pre-disked surface prior to advancing to bentonite placement. The number of passes required for pre-disking to is dependent on the prepared foundation conditions and selection of equipment.

Placement, Disking, and Compaction

Bentonite will be spread onto the uppermost 0.15 m of pre-disked surface soil. Spreading the bentonite may be accomplished from a haul truck mounted cement spreader or a tractor pulling a trailer mounted spreader. Equipment to consider for spreading bentonite are the Stoltz Site Spreader® mounted on a CAT® haul truck. The number of passes to dispense a sufficient quantity of bentonite is dependent on the selection of equipment. For the upstream dam faces it may be necessary to utilize an excavator to roughly dispense the bentonite from 1 m^3 bags, followed by manual smoothing/raking of the bentonite by laborers using manual tools such as rakes and shovels.

Following spreading of the bentonite, disking will be undertaken to mix the pre-disked native soil and bentonite. The maximum disking depth per pass is 0.15 m; hence, survey control will need to be achieved using either GPS, rod & level (horizontal levelling), or Total Station. The number of passes of the disking equipment to achieve adequate mixing will be based on the selection of equipment and informed by field studies on trial pads.

To achieve the 0.45 m soil-bentonite liner, 0.15 m layers of local material will need to be placed prior to the second and third additions of bentonite. Placement of the native soil can be completed by hauling native soil with a haul truck, dumping the material in local stockpiles, and then spreading the soil to the target 0.15 m lift thickness with a dozer or grader. For each 0.15 m lift of the soil-bentonite liner system, bentonite will be spread onto the 0.15 m of native soil followed by disking to mix the native soil and bentonite, and compaction.

Compaction of each 0.15 m lift of the 0.45 m soil bentonite liner system will be accomplished with a vibratory smooth drum or sheepsfoot roller. The number of passes of the compactor will be dependent on dry density targets defined in the detailed design engineering and selection of equipment.

Grab samples of the surface soil, bentonite, and soil-bentonite mixture shall be collected and subjected to the testing procedures recommended in Section 6.4.2. Testing of the compacted soil-bentonite liner system *in-situ* shall be undertaken with the testing procedures recommended in Section 6.4.

6.3.5 Protective Component

Prior to placement of PAG material, the soil-bentonite liner system will require a protective component to protect the liners from being punctured by large waste rock, which could damage the integrity and functionality of the liner system. Two options were evaluated for this protective layer:

1. Placement of a 1 m thick over-liner layer of locally stockpiled soil.
2. Deployment of a 16 oz. non-woven geotextile.

A protective layer of 16 oz. non-woven geotextile was selected to be placed on top of the liner instead of a soil over-liner. Aside from being the lower cost of the two alternatives, the non-woven geotextile does not reduce the storage capacity of the MPs.

6.4 Quality Control and Quality Assurance

The development of an adequate geotechnical campaign, technical specifications for construction and quality controls mitigate the risk of requiring a re-design during construction. The definition of ranges for acceptable parameters ensures flexibility in design tolerances and enables foreseeing actions on possible variabilities in material quality. The design of adequate construction methodologies and its correct control can help prevent contingent quality defects due to negligence and the additional associated costs.

6.4.1 Weather Considerations

Weather and runoff conditions during construction can significantly affect the water content of the surface soil material or create hydraulic conditions different from those assumed, which could in turn cause changes in the liner design. For this reason, the project must be continuously evaluated to make sure that the conditions found during construction are compatible with the final design.

6.4.2 Recommended Testing

It will be necessary to maintain density control and verify the in-situ hydraulic conductivity of the soil-bentonite liner system to ensure the liner will perform to specification. This will involve a combination of laboratory testing on grab samples collected in the field and *in-situ* (field based) testing.

Routine Tests

The following routine testing and visual-manual inspection shall be performed to establish the soil type and *in-situ* condition:

- Natural moisture content testing according to standard ASTM D2216;
- Particle size distribution curves shall be obtained according to standards ASTM D0422 (granular material) and ASTM D2487 (fine material). These shall be obtained for samples of surface soils, bentonite, and soil-bentonite liner material; and
- Permeability tests shall be performed according to standards ASTM D2434 (granular material) and ASTM D5084 (fine material).

6.4.3 Compaction

The *in-situ* soil density can be measured by two methods:

- Sand-cone method (ASTM D1556): an excavation is made, and the weight of the extracted material is determined. The excavation volume is computed by filling the hole with sand using a calibrated recipient; and
- Nuclear methods (ASTM D2922, ASTM D3017): based on the interaction between gamma radiation and existing electrons in the soil particles. The difference between energy emitted and received is measured, which is proportional to the soil density.

A systematic on-site control program of the degree of compaction must be elaborated and implemented to determine the density and moisture content of the compacted material and compare the results with the specified limits.

The degree of compaction grade shall be verified in each lift. Control of the fill material shall be carried out continuously by visual inspection of the operations (unloading, spreading, humidification, mixing and compaction).

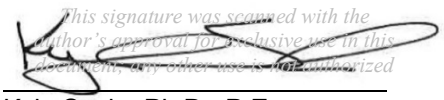
The number of control tests shall be determined for the detailed level design. No new lift shall be spread until the degree of compaction (moisture and density) has been tested and accepted.

6.4.4 Permeability Tests

The soil permeability governs the hydraulic performance of the soil-bentonite liner system. Permeability shall be verified by the use of trial pads, either prior to or during construction, by a Double Ring Infiltrometer, Guelph infiltrometer or *in situ* tests (ASTM D5126).

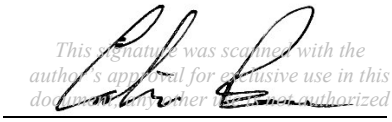
Permeability results for the soil bentonite liner must be less than or equal to $1x10^{-10}$ m/s in accordance with hypotheses made during the geotechnical design of the embankment.

7 Recommendations



- A 0.45 m soil-bentonite liner system with a hydraulic conductivity of 1E-10 m/s would be sufficient to reduce total seepage below the 2,800 m^3/day design criteria target for both the base and high cases.
- To perform a laboratory study to determine the optimal proportion of bentonite-soil blend to produce a soil-bentonite mixture with a hydraulic conductivity ≤ 1E-10 m/s.
- To perform field trials to refine the construction methodology and equipment selection, and verify the soil-bentonite liner system performs to specification with an *in-situ* hydraulic conductivity ≤ 1E-10 m/s.
- The preliminary construction methodology for the recommended 0.45 m soil-bentonite liner system will be constructed in three 0.15 m lifts:
  - Preliminary foundation preparation (clearing & grubbing) followed by pre-disking the native soil;
  - Spreading bentonite to meet the target ≤ $1x10^{-10}$ m/s hydraulic conductivity, disking the first 0.15 m lift of soil-bentonite, and compaction;
  - Placement of 0.15 m lifts of native soil, with each lift followed by application of bentonite to meet the target ≤ $1x10^{-10}$ m/s hydraulic conductivity, disking the 0.15 m lifts of soil-bentonite, and subsequent compaction.
- Quality control and quality assurance procedures should be implemented to mitigate the risk of redesign and prevent quality defects. This includes proper oversight of weather and implementation of routine testing to establish the soil type and *in-situ* condition, as well as maintaining control of the degree of compaction and permeability of the soil-bentonite liner system.

8 Closure



This technical memo, “Liner System Seepage Assessment and Construction Methodology for Tenas Management Ponds”, was prepared by SRK Consulting (Canada) Inc. to provide recommendations for a liner system that will reduce seepage rates from the Tenas Management Ponds to below allowable thresholds defined in SRK’s site water balance (SRK, 2020a).

We trust the information included meets your present requirements. If you have any questions regarding the analyses or if you require additional information, please do not hesitate to contact the undersigned.

LEAKAGE RATE A THROUGH A COMPOSITE LINER

Source:Giroud, J.P., 1997, "Equations for Calculating the Rate of Liquid Migration Through Composite Liners Due to Geomembrane Defects", Geosynthetics International, Vol. 4, Nos. 3-4, pp. 335-348.

INPUTS

A, Geomembrane area (m2)

n, Number of defects per considered geomembrane area (A)

Feature	(A) Footprint	(n) Defect density			
		Excellent	Good	Fair	poor
	m2	*1/acre*	*4/acre*	*10/acre*	*20/acre*
-	-	*1*	*4*	*10*	*20*
Control Po	386000	96	382	954	1908

C_{qo} or $C_{q\infty}$, Contact quality factor

	Good contact	Poor contact
C_{qo}	0.21	1.15
Cq ∞	0.52	1.22

C_{q0} => circular, square, rectangular

$C_{q\infty}$ => infinite length

h. hydraulic heads

h = 10 m

Note: Limitation of Giroud equation Semi-Prmb => head above geomembrane must be <=3m.

If head above the liner is >3m, the leakage rate is overpredicted (Source: Paul Hubbard, Car

ts. Thickness of the low-permeability soil component of the composite liner

ts = 7 m

CCL, compacted clay liner => typically between 0.3 to 1.5m

GCL, geosytnthetic clay liner => typicallybetween 5 and 100mm

ks, Permeability of the low-permeability soil (m/s)

ks = 7.0E-07 m/s Base Case (geomean of the mixed grain till)

ks = 1.9E-06 m/s High Case (base case ks x 2.7)

ks must be equal or less to kg (see limitations to Giroud equations)

kg 5.9E-07 => Calculation kg assumes geomembrane defect is circular

k of CCL typically between 1E-10 and 1E-9 m/s

k of GCL typically between 5-12 and 5E-11 m/s

d, Diameter of circular defect (m)

d = 3.5 mm 3.5E-03 m

(min. 0.5mm / max.25mm)

case 1: Typical for liner performance evaluation => defect area of 0.1 cm^2
(equivalent to defect diameter of 3.5 mm)

Case 2: Conservative design => defect area of 1 cm^2
(equivalent to defect diameter of 11.284 mm)

b, Width of defect (m) for an infinitely long defect

square defect with side le 3.5E-03 m

infinitely long defect with 3.5E-03 m

b and B, Width and Length (m) for a recta m

Rectangular defect with w 3.5E-03 m

Rectangular defect with le 7.0E-03

$$Q = C_{qo}\ [1+0.1\ (h/t_s)^{0.95}]\ b^{0.2}\ h^{0.9}\ k_s^{0.74} + C_{q\infty}\ [1+0.2\ (h/t_s)^{0.95}]\ (B-b)\ b^{0.1}\ h^{0.45}\ k_s^{0.87}$$

Q, Leakage rate through the geomembrane defects
Unit m^3/d

	Q per defect x # defect			
	Excellent	Good	Fair	poor
Base Cas	142	565	1412	2825
High Cas	296	1180	2946	5891

Limitations of Giroud (1997) equations

- If the defects is circular, the defect diameter should be no less than 0.5mm and not greate
- Do not use for very small defects (d<0.5mm because capillarity may prevent free flow;
- In the case of defects that are not circular, it is proposed to use these limitations for the defect width.
- The liquid head on top of the geomembrane should be equal or less than 3m
- The K of the low-permeability soil underlying the geomembrane shoul be equal to or less than a certain value kg
- Limitations to diameter width and groundwater head are linked to the experimental data that were used to deveop the semi-empirical equations

NOTES:

Q_s , Leakage rate through the geomembrane defects

n, defect density (number of defects per acre)

h, hydrauli head

A, liner footprint

ts, thickness of the low-permeability soil component of the composite liner

ks, permeabiliyy of the low-permeability soil component of the composite liner

ks must be equal or less to kg (see limitations to Giroud equations). Calculation kg assumes geomembrane defect is circular.

k of CCL typically between 1E-10 and 1E-9 m/s

k of GCL typically between 5-12 and 5E-11 m/s

Limitations of Giroud (1997) equations

- if the defects is circular, the defect diameter should be no less than 0.5mm and not greater than 25mm. Do not use for very small defects (d<0.5mm because capillarity may prevent free flow.
- The liquid head on top of the geomembrane should be equal or less than 3m. If head above the liner is >3m, the leakage rate is overpredicted (Source: Paul Hubbard, Cardiff)
- The K of the low-permeability soil underlying the geomembrane shoul be equal to or less than a certain value kg
- Limitations to diameter width and groundwater head are linked to the experimental data that were used to deveop the semi-empirical equations.

GENERAL PROPERTIES APPLIED TO ALL CASES:

Table 1 Giroud 1997: Contact quality factor Cqo or Cq ∞

	Good contact	Poor contact
C_{qo}	0.21	1.15
Cq ∞	0.52	1.22

Cq0 => circular, square, rectangular

Cq ∞ => infinite length

Cqo or Cq ∞ , Contact quality factor

Cqo	0.21
Cq ∞	0.52

r, Radius of circular defect (m)

r 5.65 mm a 100 mm^2

(diam. min. 0.5mm / max.25mm)

Giroud 2016: over the years, the practice for engineers as well as researchers has been to consider 2 holes per acre with a hole size of 100 mm^2.

Conversion factors

1 m^2 = 2.5E-04 acre

SCENARIOS

Leakage rate (m^3/d) for designs with bituminous geomembrane on top of a soil-bentonite liner

Goathorn Ck @ Telkwa River = 192.8 km2
Model represents only about 2% of the Bulkey watershed

Appendix H – Analysis of the Potential Groundwater Quality at Post-closure in the Private Wells Area

Estimation groundwater quality downgradient of the Project (WQS09), along pathways towards private wells - Base Case

Calculation concentration of the groundwater flowing into the Telkwa River Valley:

Three private domestic wells (Goalder, Mapletoft, Baker) are shown to be within the potential paths of mine affected groundwater (i.e., based on particle paths predictions for post-closure conditions). These wells are located in the Telkwa River valley, and pumping groundwater from the fluvial aquifer at a relatively shallow depth (15 to 30m deep). To evaluate the potential maximum effects from the Project to the groundwater quality of the fluvial aquifer, it is assumed:

* The mine affected groundwater reached final discharge locations (i.e., post-closure, pseudo -steady state conditions);

* The groundwater pumped by the three private domestic wells corresponds exclusively to the groundwater coming from southern side of the Telkwa River valley, and discharging upstream of WQS09. The groundwater contributions from the northern side of the Telkwa River, and from the fluvial aquifer upstream of the project influence are not accounted;

* The mass of constituents in groundwater is conserved (i.e., transport of mine affected groundwater by advection only, no diffusion or dispersion, and conservation of mass, no natural attenuation).

(1) **[Qw x Cw] = [Qb x Cb] + [Qm x Cm]**
(2) **[Qm x Cm] = [Q1 x C1] + ... + [Qi x Ci]**

For a unit volume Qw = 1, Cw can be expressed using the estimated percentage contributions relative to each sources predicted by the groundwater model (i.e., particle path analyses):

(3) **Cw = Pb x Cb + + (Pm x P1) x C1 ... + (Pm x Pi) x Ci**

Qw, groundwater flow into the Telkwa River valley.
Cw, concentration of the groundwater into the Telkwa River valley.
Qb, flow contribution from background groundwater.
Cb, concentration of background groundwater (baseline).
Pb, percentage contribution of background groundwater into the Telkwa River valley.
Qm, flow contribution from mine affected groundwater.
Cm, concentration of mine affected groundwater.
Pm, percentage contribution of mine affected groundwater into the Telkwa River valley.
Qi, flow contribution from mine feature i.
C_i, concentration of from mine feature i (source terms).
P_i, percentage contribution of from mine feature i to total mine affected groundwater

Model: 08-05l-lc (PostClosure) - Base Case

ID	% Baseflow Bckgrnd	% Baseflow Mine	Detailed distribution of mine affected baseflow					
			NMP	EMP	WMP	TCP	PL 909	SWR 901
			%	%	%	%	%	%
WQS09	95.6%	4.4%	13.4%	30.9%	55.3%	na	na	0.5%
WQS09 (TCL 25y)	95.2%	4.8%	12.2%	28.2%	50.5%	8.6%	na	0.4%

Note: Modelled WQS09 GW'shed corresponds only to the southern contribution from the valley.

Estimation groundwater quality downgradient of the Project (WQS09), along pathways towards private wells - HighCase

Calculation concentration of the groundwater flowing into the Telkwa River Valley:

Three private domestic wells (Goalder, Mapletoft, Baker) are shown to be within the potential paths of mine affected groundwater (i.e., based on particle paths predictions for post-closure conditions). These wells are located in the Telkwa River valley, and pumping groundwater from the fluvial aquifer at a relatively shallow depth (15 to 30m deep). To evaluate the potential maximum effects from the Project to the groundwater quality of the fluvial aquifer, it is assumed:

* The mine affected groundwater reached final discharge locations (i.e., post-closure, pseudo -steady state conditions);

* The groundwater pumped by the three private domestic wells corresponds exclusively to the groundwater coming from southern side of the Telkwa River valley, and discharging upstream of WQS09. The groundwater contributions from the northern side of the Telkwa River, and from the fluvial aquifer upstream of the project influence are not accounted;

* The mass of constituents in groundwater is conserved (i.e., transport of mine affected groundwater by advection only, no diffusion or dispersion, and conservation of mass, no natural attenuation).

(1) **[Qw x Cw] = [Qb x Cb] + [Qm x Cm]**
(2) **[Qm x Cm] = [Q1 x C1] + ... + [Qi x Ci]**

For a unit volume Qw = 1, Cw can be expressed using the estimated percentage contributions relative to each sources predicted by the groundwater model (i.e., particle path analyses):

(3) **Cw = Pb x Cb + + (Pm x P1) x C1 ... + (Pm x Pi) x Ci**

Qw, groundwater flow into the Telkwa River valley.
Cw, concentration of the groundwater into the Telkwa River valley.
Qb, flow contribution from background groundwater.
Cb, concentration of background groundwater (baseline).
Pb, percentage contribution of background groundwater into the Telkwa River valley.
Qm, flow contribution from mine affected groundwater.
Cm, concentration of mine affected groundwater.
Pm, percentage contribution of mine affected groundwater into the Telkwa River valley.
Qi, flow contribution from mine feature i.
C_i,, concentration of from mine feature i (source terms).
P_i,, percentage contribution of from mine feature i to total mine affected groundwater

Model: 08-05l-hc (PostClosure) - High Case

ID	% Baseflow Bckgrnd	% Baseflow Mine	Detailed distribution of mine affected baseflow					
			NMP	EMP	WMP-In	TCP	PL 909	SWR 901
			%	%	%	%	%	%

Estimation groundwater quality downgradient of the Project and along pathways towards private wells - Base Case

Calculation concentration of the groundwater flowing into the Telkwa River Valley:

Three private domestic wells (Goalder, Mapletoft, Baker) are shown to be within the potential paths of mine affected groundwater (i.e., based on particle paths predictions for post-closure conditions). These wells are located in the Telkwa River valley, and pumping groundwater from the fluvial aquifer at a relatively shallow depth (15 to 30m deep). To evaluate the potential maximum effects from the Project to the groundwater quality of the fluvial aquifer, it is assumed:

* The mine affected groundwater reached final discharge locations (i.e., post-closure, pseudo -steady state conditions);

* The groundwater pumped by the three private domestic wells corresponds exclusively to the groundwater coming from southern side of the Telkwa River valley, and discharging upstream of WQS09. The groundwater contributions from the northern side of the Telkwa River, and from the fluvial aquifer upstream of the project influence are not accounted;

* The mass of constituents in groundwater is conserved (i.e., transport of mine affected groundwater by advection only, no diffusion or dispersion, and conservation of mass, no natural attenuation).

(1) **[Qw x Cw] = [Qb x Cb] + [Qm x Cm]**
(2) **[Qm x Cm] = [Q1 x C1] + ... + [Qi x Ci]**

For a unit volume Qw = 1, Cw can be expressed using the estimated percentage contributions relative to each sources predicted by the groundwater model (i.e., particle path analyses):

(3) **Cw = Pb x Cb + + (Pm x P1) x C1 ... + (Pm x Pi) x Ci**

Qw, groundwater flow into the Telkwa River valley.
Cw, concentration of the groundwater into the Telkwa River valley.
Qb, flow contribution from background groundwater.
Cb, concentration of background groundwater (baseline).
Pb, percentage contribution of background groundwater into the Telkwa River valley.
Qm, flow contribution from mine affected groundwater.
Cm, concentration of mine affected groundwater.
Pm, percentage contribution of mine affected groundwater into the Telkwa River valley.
Qi, flow contribution from mine feature i.
C_i, concentration of from mine feature i (source terms).
P_i, percentage contribution of from mine feature i to total mine affected groundwater

Model: 08-05z-lc (PostClosure) - Base Case

ID	% Baseflow Bckgrnd	% Baseflow Mine	Detailed distribution of mine affected baseflow					
			NMP	EMP	WMP	TCP	PL 909	SWR 901
			%	%	%	%	%	%

Estimation groundwater quality downgradient of the Project and along pathways towards private wells - High Case

Calculation concentration of the groundwater flowing into the Telkwa River Valley:

Three private domestic wells (Goalder, Mapletoft, Baker) are shown to be within the potential paths of mine affected groundwater (i.e., based on particle paths predictions for post-closure conditions). These wells are located in the Telkwa River valley, and pumping groundwater from the fluvial aquifer at a relatively shallow depth (15 to 30m deep). To evaluate the potential maximum effects from the Project to the groundwater quality of the fluvial aquifer, it is assumed:

* The mine affected groundwater reached final discharge locations (i.e., post-closure, pseudo -steady state conditions);

* The groundwater pumped by the three private domestic wells corresponds exclusively to the groundwater coming from southern side of the Telkwa River valley, and discharging upstream of WQS09. The groundwater contributions from the northern side of the Telkwa River, and from the fluvial aquifer upstream of the project influence are not accounted;

* The mass of constituents in groundwater is conserved (i.e., transport of mine affected groundwater by advection only, no diffusion or dispersion, and conservation of mass, no natural attenuation).

(1) **[Qw x Cw] = [Qb x Cb] + [Qm x Cm]**
(2) [Qm x Cm] = [Q1 x C1] + ... + [Qi x Ci]

For a unit volume Qw = 1, Cw can be expressed using the estimated percentage contributions relative to each sources predicted by the groundwater model (i.e., particle path analyses):

(3) **Cw = Pb x Cb + + (Pm x P1) x C1 ... + (Pm x Pi) x Ci**

Qw, groundwater flow into the Telkwa River valley.
Cw, concentration of the groundwater into the Telkwa River valley.
Qb, flow contribution from background groundwater.
Cb, concentration of background groundwater (baseline).
Pb, percentage contribution of background groundwater into the Telkwa River valley.
Qm, flow contribution from mine affected groundwater.
Cm, concentration of mine affected groundwater.
Pm, percentage contribution of mine affected groundwater into the Telkwa River valley.
Qi, flow contribution from mine feature i.
C_i,, concentration of from mine feature i (source terms).
P_i,, percentage contribution of from mine feature i to total mine affected groundwater

Model: 08-05z-hc (PostClosure) - High Case

ID	% Baseflow Bckgrnd	% Baseflow Mine	Detailed distribution of mine affected baseflow					
			NMP	EMP	WMP	TCP	PL 909	SWR 901
			%	%	%	%	%	%
WQS09	96.1%	3.9%	6.7%	22.2%	54.8%	na	5.0%	11.2%
WQS09 (TCL 25y)	96.1%	3.9%	6.7%	22.0%	54.5%	0.6%	5.0%	11.2%

Note: Modelled WQS09 GW'shed corresponds only to the southern contribution from the valley.

Estimation groundwater quality downgradient of the Project and along pathways towards private wells - Base Case

Calculation concentration of the groundwater flowing into the Telkwa River Valley:

Three private domestic wells (Goalder, Mapletoft, Baker) are shown to be within the potential paths of mine affected groundwater (i.e., based on particle paths predictions for post-closure conditions). These wells are located in the Telkwa River valley, and pumping groundwater from the fluvial aquifer at a relatively shallow depth (15 to 30m deep). To evaluate the potential maximum effects from the Project to the groundwater quality of the fluvial aquifer, it is assumed:

* The mine affected groundwater reached final discharge locations (i.e., post-closure, pseudo -steady state conditions);

* The groundwater pumped by the three private domestic wells corresponds exclusively to the groundwater coming from southern side of the Telkwa River valley, and discharging upstream of WQS09. The groundwater contributions from the northern side of the Telkwa River, and from the fluvial aquifer upstream of the project influence are not accounted;

* The mass of constituents in groundwater is conserved (i.e., transport of mine affected groundwater by advection only, no diffusion or dispersion, and conservation of mass, no natural attenuation).

(1) **[Qw x Cw] = [Qb x Cb] + [Qm x Cm]**
(2) **[Qm x Cm] = [Q1 x C1] + ... + [Qi x Ci]**

For a unit volume Qw = 1, Cw can be expressed using the estimated percentage contributions relative to each sources predicted by the groundwater model (i.e., particle path analyses):

(3) **Cw = Pb x Cb + + (Pm x P1) x C1 ... + (Pm x Pi) x Ci**

Qw, groundwater flow into the Telkwa River valley.
Cw, concentration of the groundwater into the Telkwa River valley.
Qb, flow contribution from background groundwater.
Cb, concentration of background groundwater (baseline).
Pb, percentage contribution of background groundwater into the Telkwa River valley.
Qm, flow contribution from mine affected groundwater.
Cm, concentration of mine affected groundwater.
Pm, percentage contribution of mine affected groundwater into the Telkwa River valley.
Qi, flow contribution from mine feature i.
C_i, concentration of from mine feature i (source terms).
P_i, percentage contribution of from mine feature i to total mine affected groundwater

Model: 08-05zb-lc (PostClosure) - Base Case

ID	% Baseflow Bckgrnd	% Baseflow Mine	Detailed distribution of mine affected baseflow					
			NMP	EMP	WMP	TCP	PL 909	SWR 901
			%	%	%	%	%	%
WQS09	97.4%	2.6%	10.0%	7.2%	81.5%	na	na	1.3%
WQS09 (TCL 25y)	97.3%	2.7%	9.9%	7.2%	80.8%	0.9%	na	1.3%

Note: Modelled WQS09 GW'shed corresponds only to the southern contribution from the valley.

Estimation groundwater quality downgradient of the Project and along pathways towards private wells - High Case

Calculation concentration of the groundwater flowing into the Telkwa River Valley:

Three private domestic wells (Goalder, Mapletoft, Baker) are shown to be within the potential paths of mine affected groundwater (i.e., based on particle paths predictions for post-closure conditions). These wells are located in the Telkwa River valley, and pumping groundwater from the fluvial aquifer at a relatively shallow depth (15 to 30m deep). To evaluate the potential maximum effects from the Project to the groundwater quality of the fluvial aquifer, it is assumed:

* The mine affected groundwater reached final discharge locations (i.e., post-closure, pseudo -steady state conditions);

* The groundwater pumped by the three private domestic wells corresponds exclusively to the groundwater coming from southern side of the Telkwa River valley, and discharging upstream of WQS09. The groundwater contributions from the northern side of the Telkwa River, and from the fluvial aquifer upstream of the project influence are not accounted;

* The mass of constituents in groundwater is conserved (i.e., transport of mine affected groundwater by advection only, no diffusion or dispersion, and conservation of mass, no natural attenuation).

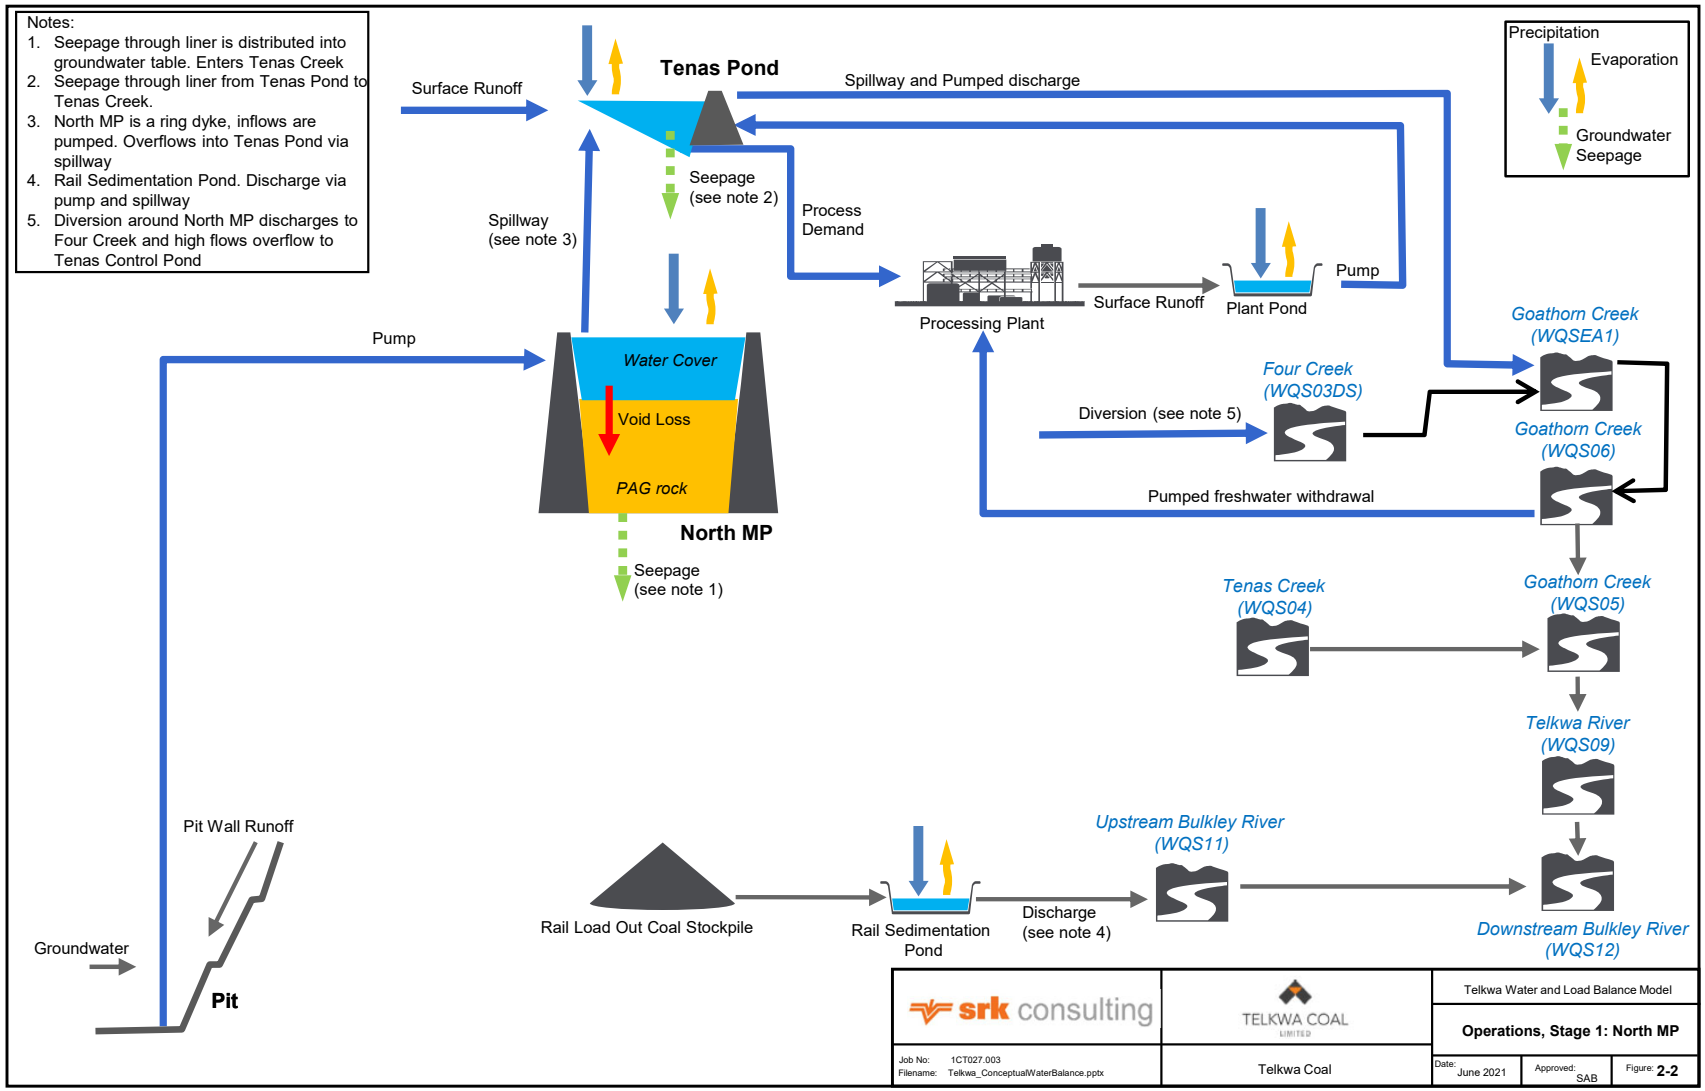
(1) **[Qw x Cw] = [Qb x Cb] + [Qm x Cm]**
(2) [Qm x Cm] = [Q1 x C1] + ... + [Qi x Ci]

For a unit volume Qw = 1, Cw can be expressed using the estimated percentage contributions relative to each sources predicted by the groundwater model (i.e., particle path analyses):

(3) **Cw = Pb x Cb + + (Pm x P1) x C1 ... + (Pm x Pi) x Ci**

Qw, groundwater flow into the Telkwa River valley.
Cw, concentration of the groundwater into the Telkwa River valley.
Qb, flow contribution from background groundwater.
Cb, concentration of background groundwater (baseline).
Pb, percentage contribution of background groundwater into the Telkwa River valley.
Qm, flow contribution from mine affected groundwater.
Cm, concentration of mine affected groundwater.
Pm, percentage contribution of mine affected groundwater into the Telkwa River valley.
Qi, flow contribution from mine feature i.
C_i,, concentration of from mine feature i (source terms).
P_i,, percentage contribution of from mine feature i to total mine affected groundwater

Model: 08-05zb-hc (PostClosure) - High Case



ID	% Baseflow Bckgrnd	% Baseflow Mine	Detailed distribution of mine affected baseflow

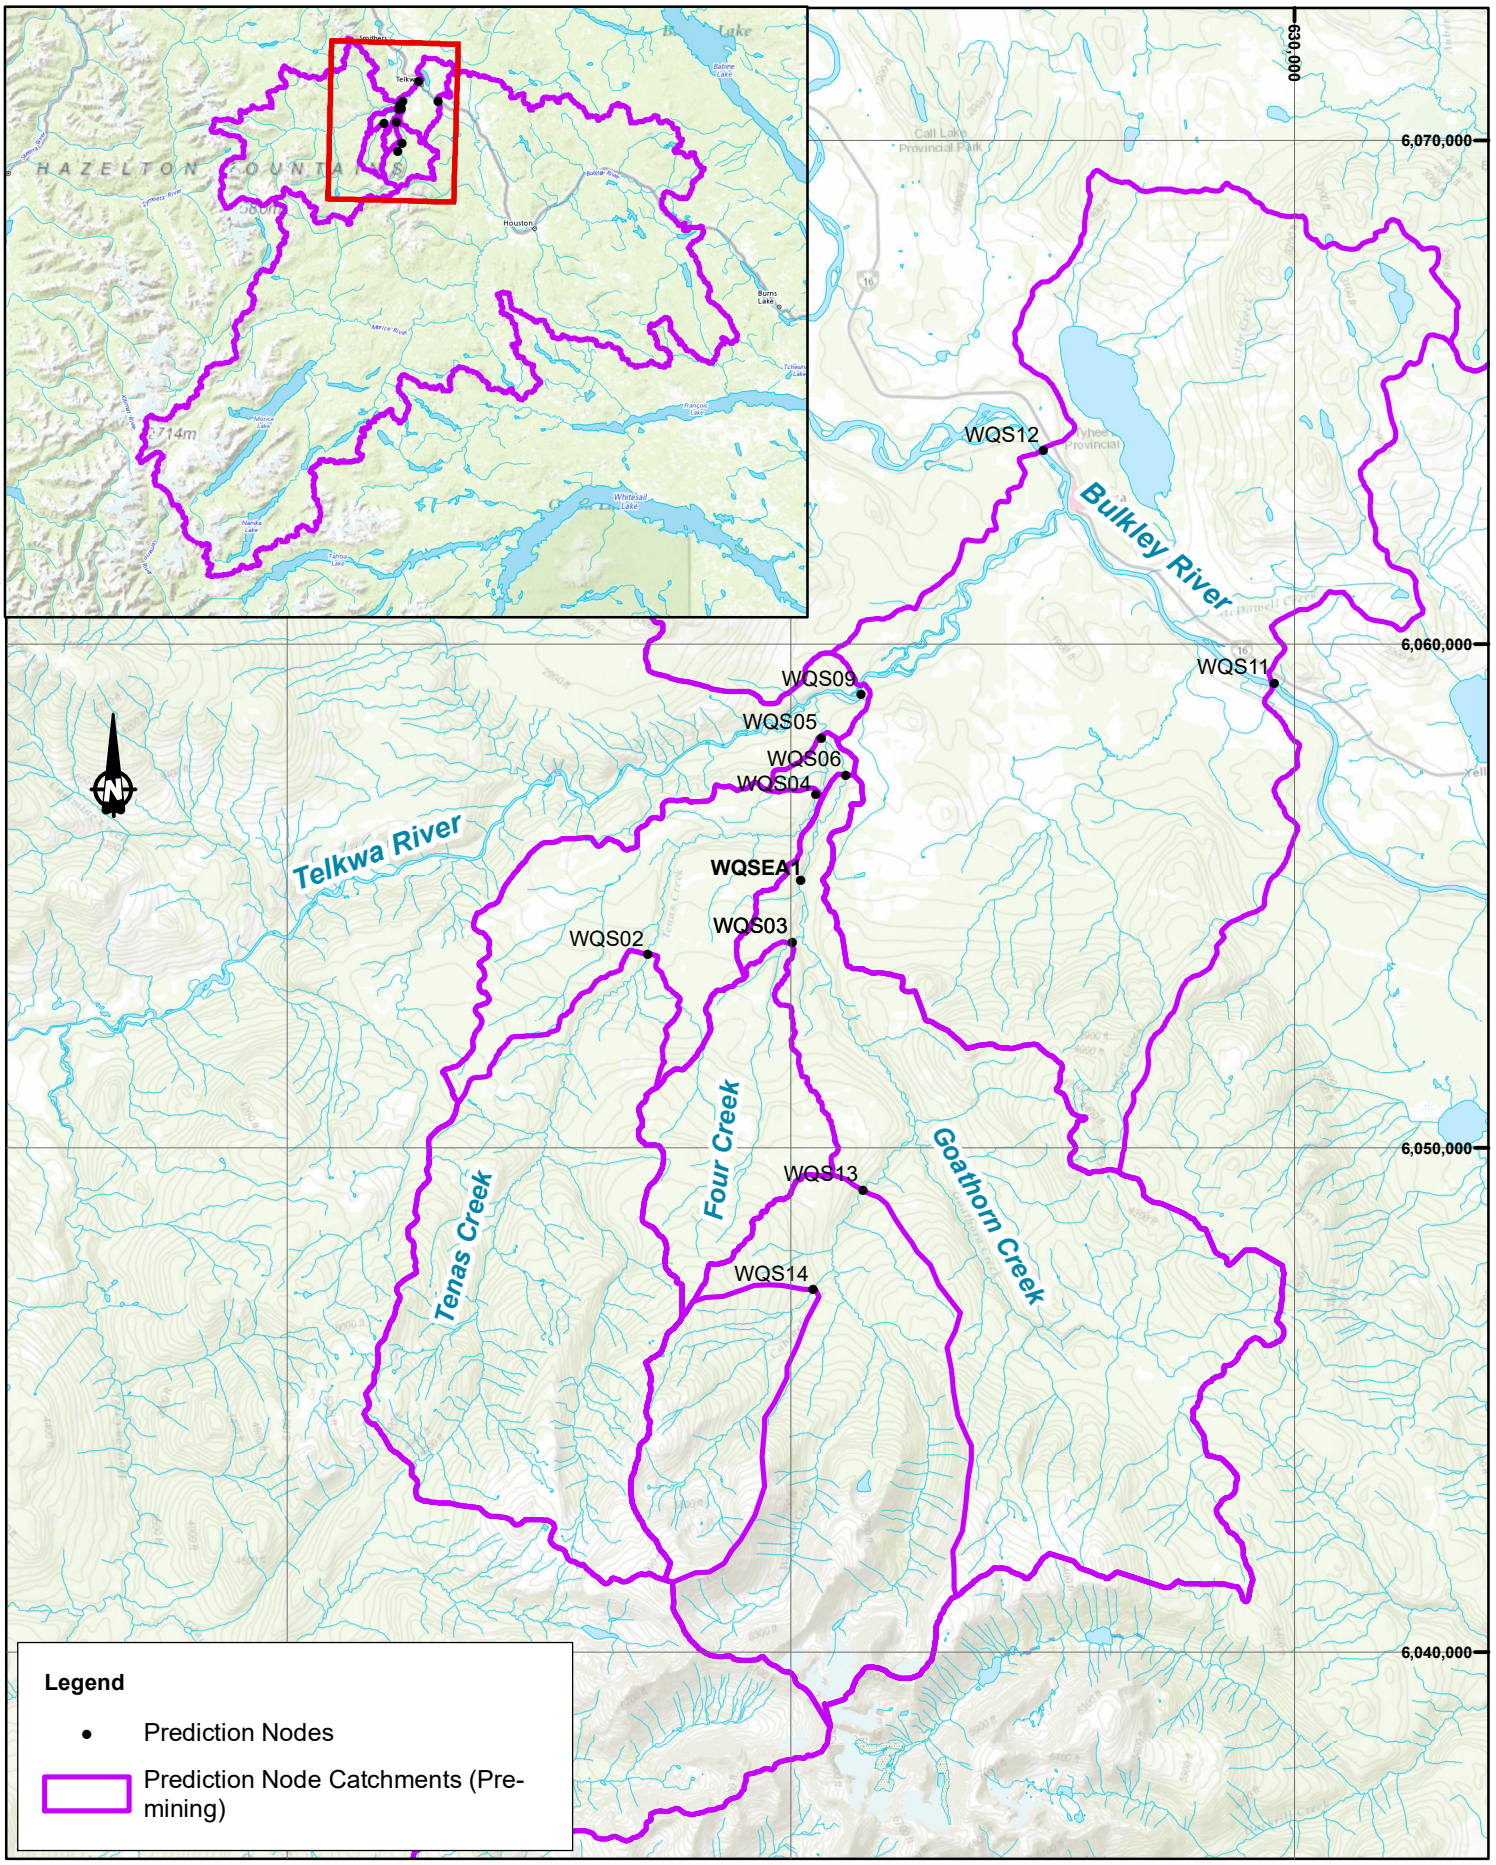
Attachment OW-040-1: Updated flow diagram figures for water and load balance model



Notes:
1. Seepage through liner is distributed into groundwater table. Enters Tenas Creek
2. Seepage through liner from Tenas Pond to Tenas Creek.
3. North MP is a ring dyke, inflows are pumped. Overflows into Tenas Pond via spillway
4. Rail Sedimentation Pond. Discharge via pump and spillway
5. Diversion around North MP discharges to Four Creek and high flows overflow to Tenas Control Pond

Executive Summary

SRK Consulting (Canada) Inc. (SRK) completed an initial dilution zone (IDZ) study for the proposed Tenas Project (the Project) in northwest British Columbia to support the Environmental Assessment Certificate Application (EA) submission for the Project in May 2022 and to address the 2024 Joint Application Information Requirements (JAIR) in anticipation that the work will be used to support future permitting of the Project. This study updates the IDZ assessment provided in the EA based on the findings of Best Achievable Technology (BAT) assessment (SRK 2025a), and updated effluent discharge information from the Water and Load Balance (WLB) model for the Project. The assessment was carried out following the Technical Guidance 11 (TG11) produced by the BC Ministry of Environment and Parks.

The IDZ is in Goathorn Creek below the confluence with a tributary that receives Project discharge from the Tenas Control Pond (TCP) and North Management Pond (NMP) during operation and post closure, respectively. This also includes discharge from the sewage treatment plant during the Operation Phase. To characterize and delineate the IDZ, three (3) credible and conservative cases were considered:

- a worst case (very worst condition),
- a reasonable worst case (worst case that potentially could occur), and
- an expected case (case corresponding to typical expected conditions).

The cases were defined based on conservative assumptions considering the in-stream flow and water quality of Goathorn Creek, and discharge rate and quality of Project effluent.

Parameters of Concern (POCs) were selected based on the findings of BAT assessment using the required regulatory guidance and updated water quality guidelines, which identified POCs through screening end of pipe Project discharge water quality results from WLB model against 80% of applicable Water Quality Guidelines (WQGs). WQGs were chosen according to the following order of preference:

- The lowest of BC Approved Water Quality Guidelines (BC AWQG) or BC Working Water Quality Guidelines (BC WWQG) for protection of freshwater aquatic life, except for molybdenum for which more stringent BC's ruminant (wildlife) was selected,
- Canadian Council of Ministers of the Environment Water Quality Guidelines (CCME WQG), or
- Environment and Climate Change Canada Water Quality Guidelines (ECCC WQG).

Parameters identified as POCs and considered in this study are listed below:

- Nitrogen Nutrients: Nitrate, Nitrite,
- Sulphate,
- Metals: Aluminum (total), Cobalt (dissolved), Copper (dissolved), Iron (total), Nickel (dissolved), Thallium (total), Zinc (dissolved), and
- Oxyanions: Molybdenum (total), Selenium (total).

To characterize the Goathorn Creek IDZ, cross-sectional channel morphology was surveyed at regularly spaced transects near the discharge location. Based on these surveys, a hydrodynamic model was developed using HEC-RAS (version 6.6, USACE 2024). The estimated stream hydraulic properties were utilized in the mixing-dilution modeling. The water quality in Goathorn Creek and its mixing and dilution

characteristics were modeled using CORMIX (version 12.0, Doneker and Jirka 2007). Estimates of the IDZ extent and corresponding plume features such as the flow occupied within the IDZ, and its length and width were obtained considering the dilution required for each POC to meet WQGs.

The modeled water quality of each POC in the Goathorn Creek was compared with the IDZ evaluation criteria for flow occupied within the IDZ and its length and width, based on TG11 guidance. For the worst case, nitrite, cobalt and selenium do not meet WQG after complete mixing and aluminum exceeds the IDZ criterion for 100 m length during operation, while aluminum and selenium do not meet WQG after complete mixing in post-closure. This case is very conservative and likely to only occur during very dry periods when the Project is likely not discharging. Emphasis was placed upon the reasonable worst case, and the expected case, both of which are still conservative but provide more realistic evaluation scenarios. The results are summarized below.

During Operation Phase:

- IDZ criteria to meet applicable WQGs are satisfied for nitrate, nitrite, sulphate, aluminum, cobalt, iron, nickel, thallium, zinc, and molybdenum for the reasonable worst and expected cases.
- The IDZ extent of selenium exceeds the TG11 guidance (100 m length) for the reasonable worst case (153 m length), but meets the guidance for the expected case. WQG is exceeded for dissolved copper due to background concentration higher than the WQG, but the effluent concentration reaches background concentrations after complete mixing.

During-Post Closure Phase:

- POCs including nitrate, nitrite, molybdenum, nickel, thallium, and zinc do not require an IDZ, as the effluent concentrations at end of pipe are below the corresponding WQGs for the IDZ cases.
- IDZ criteria based on TG11 guidance is met for sulfate, aluminum, cobalt, iron, and selenium for the reasonable worst and expected cases. The guidance is exceeded for dissolved copper with background concentration higher than the WQG, but the effluent concentration reaches background concentrations after complete mixing.

The analyses of this study provided a range for spatial extent of IDZ for conditions anticipated for worst to expected cases as outlined in TG11. Based on the reasonable worst case and the expected case, a minimum IDZ length of 153 m, and 44 m would be needed during Operation and Post-closure phase, respectively, to meet the instream WQGs for the POCs identified.

1 Introduction

The Tenas Project (the Project) is a proposed open pit steelmaking coal mine, located approximately 25 km southwest of Smithers near the Town of Telkwa, British Columbia. Surface water in the Project Footprint area will be collected through a series of management and sedimentation control ponds. Excess water will be discharged via a tributary to Goathorn Creek.

An initial dilution zone (IDZ) assessment was prepared for the Project discharge to support the Discharge Management Plan for the Project as part of the Environmental Assessment Certificate Application (EA) submission for the Project in May 2022. IDZ characterization is required to address the 2024 Joint Application Information Requirements (JAIR) for the EA. This assessment is intended to delineate the extent of IDZ for the effluent discharge from the Project under a range of discharge and mixing conditions in the receiving stream.

This technical report describes the approach, methodology, analyses, and results completed to evaluate the IDZ development from the Project's effluent discharge and its spatial extent in the receiving Goathorn Creek. The assessment was conducted following the Technical Guidance 11 (TG11) provided by the BC Ministry of Environment and Parks (ENV 2019).

1.1 Background and Scope

SRK previously completed an IDZ study for the Project in 2022 (SRK 2022) based on the information available at the time of study as part of the Environmental Assessment Certificate Application (EA) submission for the Project in May 2022. The recently completed Best Achievable Technology (BAT) assessment (SRK 2025a) identified Parameters of Potential Concern (POCs) in the discharge of treated effluent from the Project, using the water quality model results from the Water and Load Balance (WLB) model developed for the Project (SRK 2025b). This study updates the IDZ assessment based on latest findings of BAT assessment and updated effluent discharge information from the WLB model for the Project.

The objective of the IDZ Assessment is to characterize the physical mixing of the Project's discharge (effluent) into the Goathorn Creek (receiver) under different conditions and evaluate the IDZ extent for the treated effluent. The scope of work includes the following:

- Characterization of effluent and receiver water quality and quantity to develop conservative cases for IDZ evaluation,
- Hydrodynamic mixing modeling to characterize effluent dispersion and dilution in the receiver, and
- IDZ delineation to estimate the spatial extent of mixing zone downstream of the discharge point based on TG11 guidance.

1.2 Regulatory Context

The IDZ is a regulatory zone in the receiving aquatic environment where an effluent discharge is mixed and is delineated by the point at which the concentrations of parameters of concern in mixed waters are

reduced above appropriate water quality guidelines to below those limits. The release of POCs should not cause acute toxicity in the receiving environment and the discharge at the end of the pipe cannot be acutely toxic prior to mixing. The BC Ministry of Environment and Parks (ENV) considers an IDZ for authorized project discharges based on the assessment of requested effluent releases according to Provincial guidance TG11 (ENV 2019).

The allowable extent of an IDZ depends on the sensitivity and value of the receiving environment downstream of the discharge. TG11 provides some guidance on spatial dimensions for proposed IDZs. For rivers and streams (flowing water), the guidance recommends that an IDZ be limited to 25% of stream width, can occupy 25% of stream flow volume during low-flow conditions (e.g. 7Q10), and may extend up to 100 meters from the discharge point (ENV 2019). As outlined in TG11, these dimensions will vary on a case-by-case basis, depending on site-specific factors.

The potential for potential chronic toxicity is limited to within the IDZ extent, without significantly affecting aquatic life and integrity of the water body as a whole (ENV 2019). Appropriate selection of water quality guidelines (WQGs) is therefore critical in determining the extent of an IDZ. Selection of receiving WQGs is described in SRK (2025b), where the long-term average BC Approved Water Quality Guidelines (BC AWQG) and the BC Working Water Quality Guidelines (BC WWQG) for freshwater aquatic life were considered. Canadian Council of Ministers of the Environment Water Quality Guidelines for the Protection of Aquatic Life (CCME WQG) or Environment and Climate Change Canada Water Quality Guidelines (ECCC WQG) were used for parameters for which no BC AWQG or BC WWQG have yet been established.

1.3 Study Approach

TG11 provides guidance on the management of surface water quality, quantity, and discharge requirements for industrial effluent releases. Based on TG11 guidance, the following components were characterized for IDZ assessment:

- Receiver flow and water quality – estimation of flow statistics (i.e., monthly, annual) and 7Q10 low-flow, and an evaluation of representative background baseline concentrations with consideration of receiving water. A combination of conservative background water quality and low-flow conditions were used as a basis for IDZ assessment.
- Effluent discharge quantity and quality – assessment of maximum and expected discharge rates and concentrations, with consideration of site water management and long-term water quality.
- Mixing zone features – modeling and delineation of the size and extent of the mixing zone beyond which effluent dispersion restores the receiver's water quality to in-stream WQGs or background concentrations.

TG11 specifies the presentation of worst, expected and best cases for an IDZ assessment. The cases presented in this report deviates from this methodology by replacing the best case with a reasonable worst case that is commonly seen and represents a more conservative yet realistic scenario for IDZ evaluation. The 3 cases presented include: a worst case (i.e., a very worst condition), a reasonable

worst case (i.e., worst case that potentially could occur), and an expected case (i.e., case that corresponds to typical average conditions).

Table 1-1 lists the 3 cases and their corresponding flow and water quality conditions for Goathorn Creek and the discharge from the management ponds (i.e., Project Effluent). The flow and water quality conditions have been described in the hydrometeorological baseline report (SRK 2024) and the water and load balance model results (SRK 2025b). Details of these cases are described in Sections 2.2 and 2.3.

Table 1-1. Definition of IDZ assessment cases

Cases	Goathorn Creek		Project Effluent	
	Flow condition	Water quality	Effluent discharge	Effluent quality
Worst case	7Q10 low-flow [1] of the lowest dilution month	75th percentile background concentration	Maximum discharge for lowest dilution month	Maximum concentration with typical source terms
Reasonable worst case	Lowest 7Q10 flow during open water months	50th percentile background concentration	Maximum discharge for the same lowest 7Q10 month (open water)	Maximum concentration with typical source terms
Expected case	Mean flow during effluent release period [2]	50th percentile background concentration	Average discharge during effluent release period	Expected concentration with typical source terms

Source: Prepared in the text

Notes:

[1] 7Q10 low-flow: 7-day minimum flow that is expected to occur once every 10 years.

[2] Open water season (May-Oct) is the effluent release period for the Operation phase, while year-round discharge occurs in the Post-closure phase.

Mixing and dilution modeling was conducted to evaluate the IDZ extent for POCs for the worst, reasonable worst and expected cases and compared against TG11 guidance. The hydraulic and mixing modeling approach are presented in Section 3 and the IDZ delineation results are provided in Section 4.

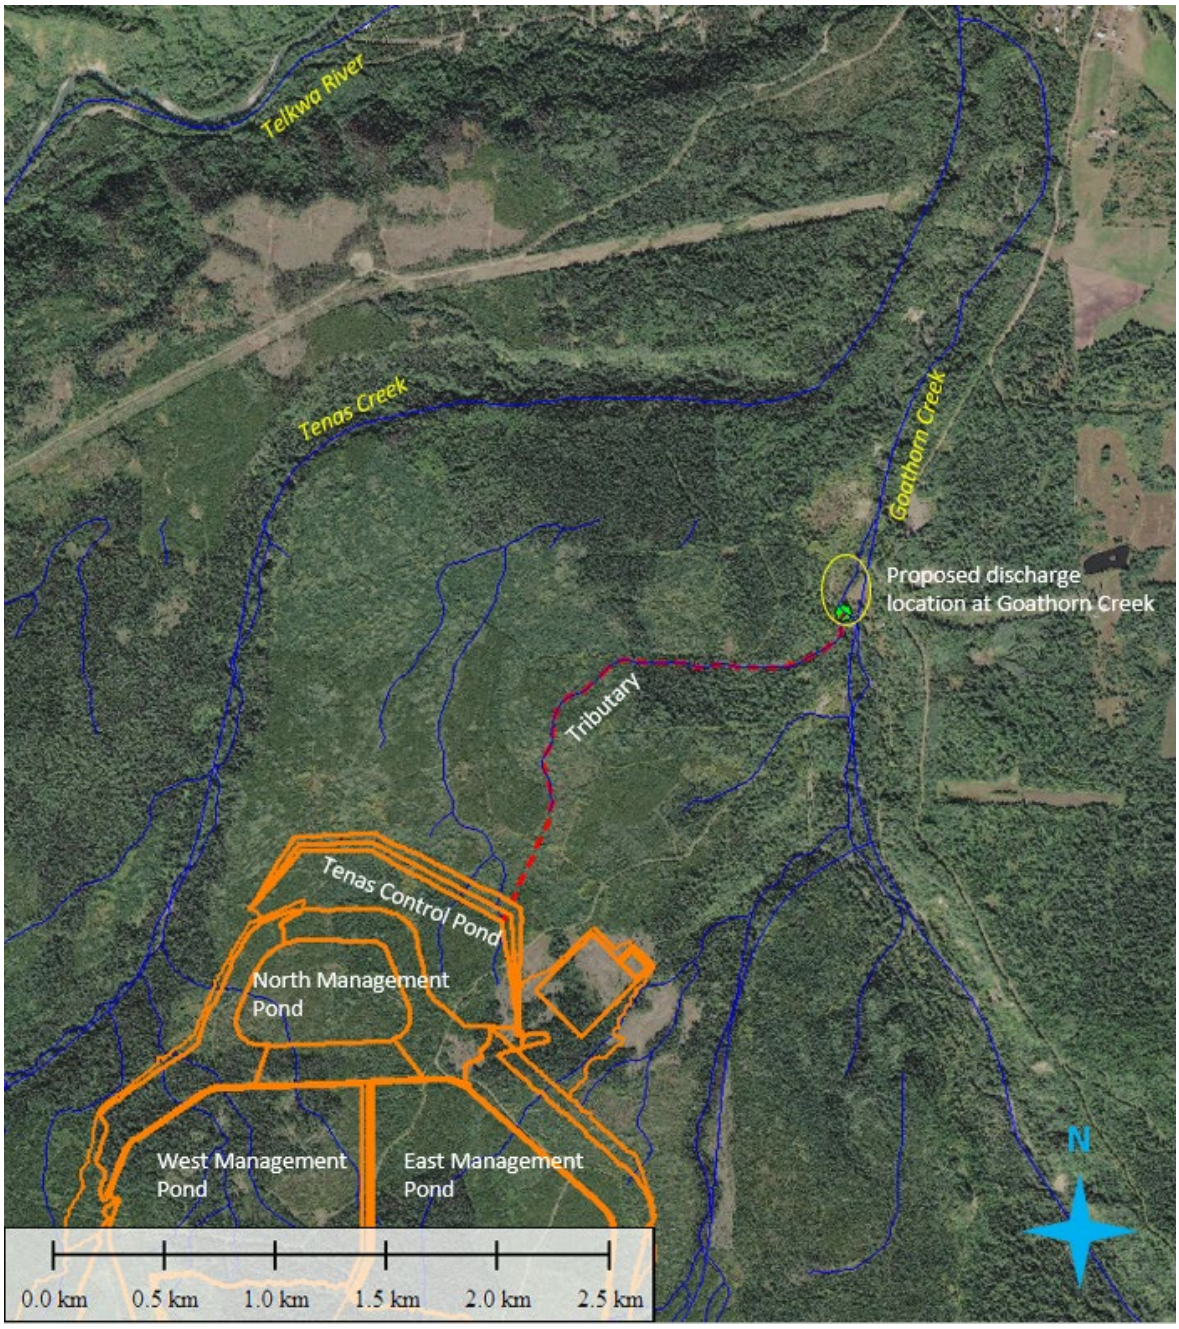
2 Site Overview and Input Characterization

2.1 Site Description and Effluent Discharge

The management ponds (i.e., East, West and North Management Ponds) for the Project will collect surface water from the active mine area. The Tenas Control Pond (TCP) will be constructed downstream of mining infrastructure and will collect water from the management ponds and upstream mining activities prior to discharging excess water to the aquatic environment. Discharge will be directed towards an ephemeral tributary of Goathorn Creek (Figure 2-1). Assessment of alternative discharge locations at a scoping level indicated that this location is beneficial in terms of water management, disturbance, and dilution capacity. A sewage treatment plant will operate onsite that will also discharge treated sewage effluent to the same tributary of Goathorn Creek during open-water season and will mix with the overall Project's discharge.

Goathorn Creek is a tributary of Telkwa River and flows along the eastern and northern extents of the Project. It is a braided creek with moderate width. Project discharge from the pond is conveyed to the Goathorn Creek through a tributary channel. This channel is typically steep, and the natural slope carries water downstream, ultimately discharging water along the left bank of Goathorn Creek. The tributary is not fish bearing above the barrier, and erosion protection will be installed along the tributary to the confluence with Goathorn Creek (SRK 2021a). During the Operation phase (Year 0 to Year 22), the TCP discharges only during the open water season months and mixes with treated sewage effluent in the tributary channel. The TCP will be decommissioned upon closure (after year 25) and excess water will be released from the North Management Pond (NMP) through the same tributary channel towards Goathorn Creek.

Water quality in Goathorn Creek has the potential to be affected by mining operation. The primary pathways for potentially affecting water quality, sources and receptors to the creek have been described in the Tenas Project Conceptual Site Model (SRK 2021b). For ease of reference, the Conceptual Site Model for the Tenas Project is found in Chapter 1, Project Overview, Appendix 1-T (App01.0-T_CSM-WaterModel_May2022-.pdf). The identified receptors including mammals, fish, amphibians, and human health were considered in the selection of the most appropriate water quality threshold criteria for the IDZ assessment described in Section 2.3.1.



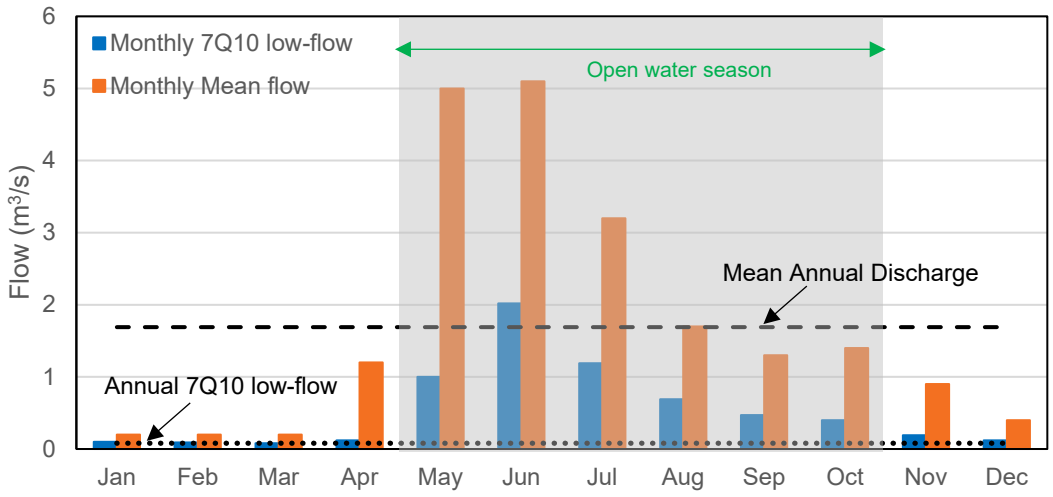


Figure 2-1. Location of proposed effluent discharge from the Project to Goathorn Creek

2.2 Flow Characterization

Goathorn Creek is the receiving environment for the Project discharge from the TCP during the Operation phase and NMP upon closure. Hydrologic estimates for the creek were calculated based on the synthetic record of the Goathorn hydrologic station, which was developed based on scaling from the Goathorn Creek Water Survey of Canada (WSC) station long-term data. The hydrology and detailed flow estimates for the creek are described in the Hydrometeorological Baseline Report (SRK 2024).

The hydrograph of Goathorn Creek is dominated by meltwater in freshet (Figure 2-2), with a mean annual discharge of 1.7 m^3/s at the Goathorn hydrologic station (SRK 2024). Low flows typically occur in late fall and winter. The annual 7-day consecutive low flow during a 10-year return period (7Q10) is expected to be 0.08 m^3/s at the Goathorn hydrologic station.

Table 2-1 outlines the monthly and annual flow statistics based on Goathorn-Hydro station data. Monthly 7Q10 low-flow estimates range from 0.08 – 2.0 m^3/s. During the open water season (i.e., May – October), the monthly mean flow in the creek at Goathorn-Hydro station ranges between 1.1 and 5.1 m^3/s, with an average of 2.9 m^3/s.

Project discharge from the TCP (during Operation phase) and the NMP (after closure) into the Goathorn Creek tributary was obtained from the water and load balance (WLB) model for the Project Footprint. Long-term discharges to the receiving environment were estimated considering the Project Case condition with expected groundwater seepage, typical source terms and average hydrology (SRK 2025b).

Monthly maximum and average discharges from the TCP (during operations until 2048, Year 22) and the NMP (during Post-Closure after 2048, Year 22) were obtained from the long-term WLB model results (Figure 2-3). TCP discharge in operation occur in the open water season. Based on average hydrologic condition predictions, discharge from TCP is highest in May, with maximum and average rate of 0.26 and 0.19 m^3/s, respectively. The closure discharge from NMP will be highest in April.

Figure 2-3. Monthly Project discharge from (a) Tenas Control Pond (TCP) during the Operation phase, and (b) North Management Pond (NMP) upon closure

The lowest dilution capacity occurs at low-flow in Goathorn Creek with high Project discharge. The IDZ evaluation cases for worst, reasonable worst and expected conditions were developed conservatively considering the low-dilution periods during the Operation phase and after closure.

Among the summer open-water season months (May – October) of effluent release during the Operation phase, the 7Q10 flow is lowest is October (Table 2-1). However, the dilution capacity is lowest in May, which corresponds to relatively low monthly 7Q10 condition (Figure 2-2) with maximum Project discharge (Figure 2-3a). Conservative IDZ cases based on combinations of Project discharge rates and in-stream flow conditions were developed for operation as follows:

- Worst case: Maximum monthly Project discharge (May) with the May 7Q10 low-flow conditions, representing lowest dilution condition.
- Reasonable worst case: Lowest monthly 7Q10 flow during open water season (October) and the corresponding monthly maximum discharge during this time (October).
- Expected case: Mean streamflow during effluent release period (May – October) with average Project discharge over the same period.

Discharge from the NMP after closure is assumed to occur year-round with no operational controls in-place to store water. The dilution capacity is lowest in April, when the Project discharge is maximum and Goathorn Creek may still be flowing below freshet flows. Conservative IDZ cases based on combinations of Project discharge rates and in-stream flow conditions were developed for the Post-closure phase as follows:

- Worst case: Maximum monthly Project discharge (April) with the April 7Q10 low-flow conditions, representing lowest dilution condition.
- Reasonable worst case: Lowest monthly 7Q10 flow during open water season (October) and the corresponding monthly maximum discharge during this time (October).
- Expected case: Mean annual flow in the stream (year-round effluent release) with average Project discharge over the same period (January – December).

Table 2-2 outlines the Goathorn Creek flow and Project discharge conditions selected for the IDZ evaluation cases. It should be noted that the worst case for Post-closure phase corresponds to the maximum discharge (0.30 m^3/s) from NMP during 7Q10 flow conditions, with the discharge rate being 2.5 times higher than the in-stream flow (flow ratio 0.4:1). This case is not realistic as the WLB model predictions represent average hydrology conditions, and the 7Q10 flow is expected to occur only during a very dry period with corresponding decrease in discharge from the Project.

A WLB model simulation of 1-in-100-year dry period for two consecutive years indicated that the maximum discharge from the NMP would be 0.071 m^3/s which corresponds to a flow ratio of 1.7:1. Therefore, a conservative but realistic 1:1 flow ratio condition was also evaluated for the worst case in post-closure and modeled for IDZ delineation.

Table 2-2. Flow Summary for IDZ Evaluation Cases

Cases	Goathorn Creek		Effluent Release		Flow ratio [1]
	Flow condition	***Flow (m^3/s)***	***Discharge condition***	***Discharge (m^3/s)***	
Operation (discharge from Tenas Control Pond)					
Worst case	7Q10 low-flow of the lowest dilution month (May)	1.0	Maximum discharge for the lowest dilution month (May)	0.26	3.9:1
Reasonable worst case	Lowest 7Q10 flow during open water months (Oct)	0.4	Maximum discharge for the same open water month (Oct)	0.035	11.4:1
Expected case	Mean flow during effluent release period (May – Oct)	2.9	Average discharge during effluent release period (May – Oct)	0.074	38.6:1
Post Closure (discharge from North Management Pond)					
Worst case	7Q10 low-flow of the lowest dilution month (April)	0.12	Maximum discharge for the lowest dilution month (April)	0.30 (0.12)[2]	0.4:1 (1:1)[2]
Reasonable worst case	Lowest 7Q10 flow during open water months (Oct)	0.4	Maximum discharge for the same open water month (Oct)	0.055	7.3:1
Expected case	Mean flow during effluent release period (Jan – Dec)	1.7	Average discharge during effluent release period (Jan – Dec)	0.043	39.3:1

Notes:

[1] Corresponds to ratio of Goathorn Creek flow to effluent discharge rate.

[2] Represents a realistic case with 1:1 flow ratio.

2.3 Water Quality Characterization

Water quality characterization for each of the IDZ cases, including background baseline water quality in Goathorn Creek, water quality guidelines, water chemistry of the effluent releases and corresponding POCs, is discussed in the following sections.

2.3.1 Water Quality Guidelines

Water quality guidelines (WQG) for the Goathorn Creek receiving environment were established based on applicable provincial or federal guidelines. WQGs were chosen according to the following order of preference (SRK 2025a):

- The lowest of BC Approved Water Quality Guidelines (BC AWQG) or BC Working Water Quality Guidelines (BC WWQG) for protection of freshwater aquatic life,
- Canadian Council of Ministers of the Environment Water Quality Guidelines (CCME WQG) when BC Guidelines are unavailable, or
- Environment and Climate Change Canada Water Quality Guidelines (ECCC WQG) when the above are unavailable.

The only exception to the use of BC WQG aquatic life guidelines was for molybdenum (total), for which BC's ruminant (wildlife) was chosen as the WQG as it was lower than aquatic receptors and was reasonably applicable for this Project (SRK 2025b). In the absence of chronic WQG, short-term BC acute WQG was used for total iron. For guidelines that depend on toxicity-modifying factors, medium background values from background baseline datasets within each creek were used.

The WQGs were applied to screen for POCs and delineate IDZ in the receiving Goathorn Creek.

2.3.2 Parameters of Concern

POCs in the effluent releases were identified by screening Project end of pipe discharge water quality results from the Tenas Project WLB model (SRK 2025b) against the WQGs. The BAT assessment used the modeled surface and groundwater discharge concentrations as a basis for identifying POCs (SRK 2025a). Parameters with modelled discharge concentrations greater than 80% of applicable WQGs at end of pope were identified as POCs. The same approach was used in this study. Exception from BAT assessment applies for cobalt for which the BC AWQG was updated from total to dissolved component. Also, thallium (total) was identified as a POC based on the recent WQG.

Parameters identified as POCs and considered in this study are listed below:

- Nitrogen Nutrients: Nitrate, Nitrite,
- Sulphate: Sulphate,
- Metals: Aluminum (total), Cobalt (dissolved), Copper (dissolved), Iron (total), Nickel (dissolved), Thallium (total), Zinc (dissolved), and
- Oxyanions: Molybdenum (total), Selenium (total).

2.3.3 Background Water Quality

The background baseline water quality information for Goathorn Creek has been described in SRK (2025b). Baseline water quality monitoring indicated that exceedances of WQGs have occurred historically in Goathorn Creek for total and dissolved aluminum, dissolved copper, and total iron. In analyzing the receiving water quality data, values less than the method detection limit (MDL) were assumed to be equal to the MDL to remain conservative.

The IDZ assessment utilized the 50th (median) and 75th percentile concentrations of the water quality parameters, with the upper percentile used to represent the worst case as a conservative approach. The 50th percentile background concentration was used for the reasonable worst case and the expected case.

WQGs of Goathorn Creek and the 50th and 75th percentile background concentration of each POCs are presented in Table 2-3. These are utilized in evaluating exceedances and estimating IDZ extent for each case evaluated in the study. Among the POCs considered, background concentration of dissolved copper (50th and 75th percentile) was higher than the in-stream WQG.

Table 2-3. Background concentration and long-term water quality guidelines for Goathorn Creek

Parameter	Goathorn Creek Background Concentration (mg/L)		Water Quality Guideline (WQG)	
	50th Percentile	75th Percentile	Value (mg/L)	Source
Nitrate-nitrogen	0.041	0.054	3	BC AWQG
Nitrite-nitrogen	0.0005	0.0009	0.02	BC AWQG
Sulphate	24	31	218	BC AWQG
Aluminum, total[1]	0.092	0.23	0.27	BC AWQG
Cobalt, dissolved	0.00005	0.00005	0.00045	BC AWQG
Copper, dissolved[1, 2]	0.0014	0.0021	0.0013	BC AWQG
Iron, total	0.085	0.27	1	BC Acute WQG
Molybdenum, total	0.00047	0.00054	0.034	BC ruminant wildlife guideline
Nickel, dissolved[1]	0.00025	0.00025	0.0022	BC WWQG
Selenium, total	0.000086	0.00012	0.002	BC AWQG
Thallium, total	0.000005	0.000005	0.00003	BC AWQG
Zinc, dissolved[1]	0.0010	0.0015	0.0074	BC AWQG

Notes:

[1] Guideline dependent on toxicity-modifying factors, calculated based on medium background values from baseline dataset.

[2] Background baseline concentration higher than in-stream WQG.

2.3.4 Effluent Water Quality

Long-term estimates of effluent water quality were developed from the WLB modeling results from pre-Project conditions, through Operation and Post-closure phases (SRK 2025b). These modelled predictions incorporate variability in hydrologic conditions, groundwater conditions and geochemical source terms. Results were presented in terms maximum and average concentrations for expected source terms, considering two 6-month periods – the open water period, denoted as summer (i.e., May through October) and the winter period, where streamflow is dominated by groundwater recharge (i.e., November through April).

To represent the IDZ cases, statistics on the water quality time series were selected. Since the Project release from the TCP is discharged in open water season, summer statistics were used to define the IDZ cases for the Operation phase. Concentrations of the POCs for the worst case and the reasonable worst case were represented by maximum concentration, while expected case corresponded to average summer concentration with expected source term (Table 2-4).

After the Operation phase, the TCP is decommissioned, and discharge controls are no longer available. Project discharge from the NMP is high in March and April, which have the least dilution capacity after closure. Therefore, winter statistics were selected for IDZ Post-closure cases, since these provide conservative estimates compared to summer concentrations. The winter maximum concentration was selected for the worst and reasonable worst cases, and the average concentration was used for the expected case.

WLB model results indicated that when TSS in treated effluent is assumed maximum (35 mg/L), the total iron concentration exceeds the acute guideline of 1.0 mg/L. If the TSS is reduced by half, the iron concentrations are below the acute limit. This is an artifact of assuming high TSS in the effluent. Furthermore, Borealis Environmental Consulting Incorporated reviewed the POC acute toxicity concentrations and determined that total iron concentrations do not exceed LC50 values for rainbow trout and Daphne and therefore the modelled effluent is not expected to be acutely toxic (SRK 2025a).

Table 2-4. Effluent water quality characterization for the identified POCs

Parameter	Effluent Concentration (mg/L)

2.4 Sewage Effluent

The sewage treatment plant (STP) will discharge treated effluent into the tributary of Goathorn Creek. The treated effluent is held in a pond over winter and discharged during the open-water season from May through September. The average discharge rate from the STP is 41.5 m^3/day (0.0005 m^3/s). The effluent water quality was obtained from WLB modeling (SRK 2025b) and is presented in Table 2-5. Considering TCP discharge rate (Table 2-2) and corresponding water quality (Table 2-4) for the three IDZ cases, concentrations in the tributary of Goathorn Creek were obtained based on mass balance approach assuming a fully mixed condition.

After mixing of sewage effluent and TCP discharge, total ammonia concentration in the tributary was below the WQG (1.5 mg/L) and therefore Ammonia was not considered a POC. Nitrate-nitrogen and nitrite-nitrogen was identified as POCs (refer to Section 2.3.2), and the mixed concentrations in the tributary were used for IDZ modeling at the Goathorn Creek.

According to BC Municipal Wastewater Regulation, a dilution ratio of 10:1 is required for sewage effluent (Radloff 2021), which will be supplied by the discharge from the Tenas Control Pond during the Operation phase. The dilution for the IDZ cases is high (> 70), and the required water to mix with sewage effluent will be met throughout operations based on available water in the TCP.

Table 2-5. Water quality of treated sewage effluent

Parameter	Cases	Effluent concentration (mg/L)		Concentration in tributary [1] (mg/L)	Dilution [2]
		STP	TCP		
Nitrate	Worst	36.9	4.3	4.4	532
	Reasonable worst	36.9	4.3	4.7	74
	Expected	36.9	1.2	1.2	155
Nitrite	Worst	0.1	0.099	0.099	532
	Reasonable worst	0.1	0.099	0.099	74
	Expected	0.1	0.023	0.023	155
Total ammonia	Worst	1.9	0.56	0.56	532
	Reasonable worst	1.9	0.56	0.58	74
	Expected	1.9	0.13	0.14	155

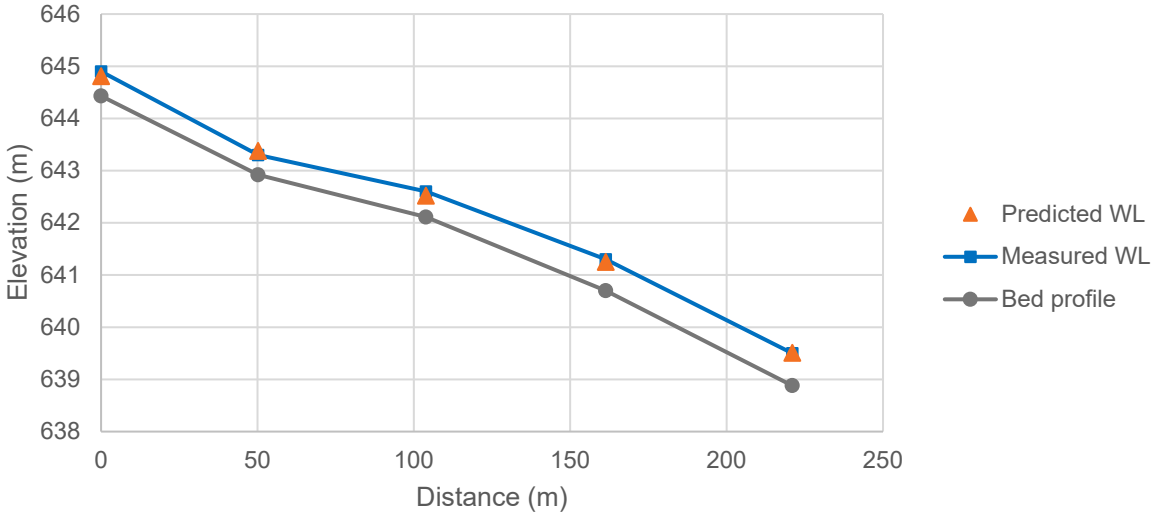
2.5 Stream Survey

A field survey was carried out on October 30, 2020, in Goathorn Creek by DWB Consulting Services Limited (2020). During the survey, the average streamflow in the creek was 1.2 m^3/s, based on the real-time hydrometric monitoring at Water Survey of Canada station 08EE008 (WSC 2020). This is comparable to the flow rate used in the reasonable worst case (i.e., 0.99 m^3/s) which corresponds to the 7Q10 flow during freshet (May).

To obtain a detailed description of the Goathorn Creek IDZ, cross-sectional measurements were carried out at five (5) locations upstream and downstream of the proposed discharge point (Figure 2-4). The tributary discharges from the left bank at the creek, and a section (denoted by section C) was measured at this discharge location. Two more sections upstream (sections A and B) and two sections downstream (sections D and E) were surveyed, covering about a 220 m reach near the discharge location. In each section, measurements were taken at close intervals to capture the local variation of channel depth. Locations of the overbank points and water levels were also noted. The presence of boulders and cobbles in the creek makes the cross-sectional shapes highly irregular (Figure 2-4). The bed profile and the channel slope were obtained from these cross-sectional measurements. The estimated bed slope for the surveyed reach is about 2.3% (DWB 2020).

Figure 2-4. Surveyed cross sections near the Goathorn Creek discharge point



3 Hydraulic and Mixing Modeling

Stream hydraulic properties were utilized to develop mixing-dilution model, as these govern dispersion characteristics in the receiving environment. HEC-RAS (version 6.6, USACE 2024) was utilized to build a hydrodynamic model of the Goathorn Creek and develop inputs for mixing modeling. The water quality in the Goathorn Creek and its mixing and dilution characteristics were modeled using CORMIX (version 12.0, Doneker and Jirka 2007), which is a computer-aided system for the analysis, prediction, and design of regulatory mixing zones, and is supported by the US Environmental Protection Agency.

3.1 Hydraulic Model Development

The HEC-RAS model domain was constructed using the surveyed cross sections measured upstream and downstream of the discharge point, covering about 220 m long reach of the Goathorn Creek. Because of the highly irregular geometry, cross sections were interpolated at a 2 m spacing for better representation of hydraulic features. During the cross-section survey, average flow at the Goathorn Creek was 1.2 m^3/s, which was applied as the upstream boundary condition. The model was set to a normal depth boundary condition at the downstream model extent.

Since the IDZ assessment typically uses low-flow conditions, the variation in roughness between the channel and overbank locations is not very important, and a single channel roughness value was assigned for the entire reach. The model was calibrated by adjusting Manning's roughness coefficient 'n' to maintain observed water depths in the upstream sections. The estimated roughness coefficient was 0.14, typical of the large cobbles and boulders observed at the site. This also falls within the range of acceptable roughness values found in literature (USACE 2024). The measured and simulated water surface elevation agreed very well, with a correlation coefficient, R^2 = 0.999 (Figure 3-1), indicating an appropriate selection of the model parameters.

Figure 3-1. Comparison between the measured and simulated water surface elevation

3.2 Hydraulic Characterization Results

The calibrated model was utilized to simulate the Goathorn Creek flow conditions for the three cases – worst, reasonable worst and expected conditions, during the Operation and Post-closure phases. For each case, the creek flow, and the corresponding effluent discharge rate (Table 2-2) were considered for the creek's total flow. Various hydraulic parameters, such as depth, velocity, and width, were averaged over the IDZ reach downstream of the discharge location. Table 3-1 highlights the hydraulic characteristics for each case, which were utilized in the mixing-dilution modeling described in Section 3.3.

Table 3-1. Hydraulic features of Goathorn Creek for different cases

Parameter	Calibration	Operation			Post Closure		
		Worst case	Reasonable worst case	Expected case	Worst case	Reasonable worst case	Expected case
Total flow (m^3/s)	1.2	1.26	0.44	2.93	0.24[2]	0.46	1.73
Slope (m/m) [(1)]	0.023	0.023	0.025	0.023	0.025	0.025	0.023
Average Depth (m)	0.31	0.32	0.20	0.43	0.15	0.20	0.36
Average Velocity (m/s)	0.49	0.49	0.37	0.61	0.32	0.38	0.53
Average Width (m)	9.1	9.2	6.8	11.8	5.5	6.8	9.9

Notes:

[1] Slope of the energy grade line.

[2] Corresponds to the case with 1:1 flow ratio.

Using the calibrated hydrodynamic model, velocity distribution and the corresponding cumulative discharge were analyzed for the Goathorn Creek. The cumulative discharge, *q*, represents the volumetric flow rate which occurs between the bank and a given position within the channel, and is equal to zero at one bank and equal to the total discharge (Q) at the other bank. The cumulative discharge distribution at the surveyed sections of the Goathorn Creek is illustrated in Figure 3-2 where q = 0 at the left bank and q = 1.2 m^3/s at the right bank of the creek. The distribution is similar for most cases, except for section A (which is narrow) and section D (with divided flow).

Source: Z: \1CT027.003 Telkwa/2020 EA Water Management Support\900_Discharge_Mgmt\IDZ_study\ CORMIX_Modeling\ TelkwaIDZ_CORMIX_ModelResults_rev04_nst.xlsm

Figure 3-2. Cumulative discharge distribution at Goathorn Creek sections

The distribution of cumulative discharge lines in a channel provides an indication of the overall flow pattern that is important for constituent transport. The closely spaced discharge lines, as shown in Figure 3-3, represent areas of large depth and higher velocities in the Goathorn Creek. Also, the sections are typically shallow towards the left bank, so wider plume widths are expected for effluent discharge, which exceeds that provided in the TG11 guidance. For example, Section C (discharge location) and downstream sections occupy 37-56% channel width for 25% flow. As a result of this site-specific shallow-flow configuration, wider plume width criterion (40% of channel width) was used for IDZ delineation (see Table 4-1).

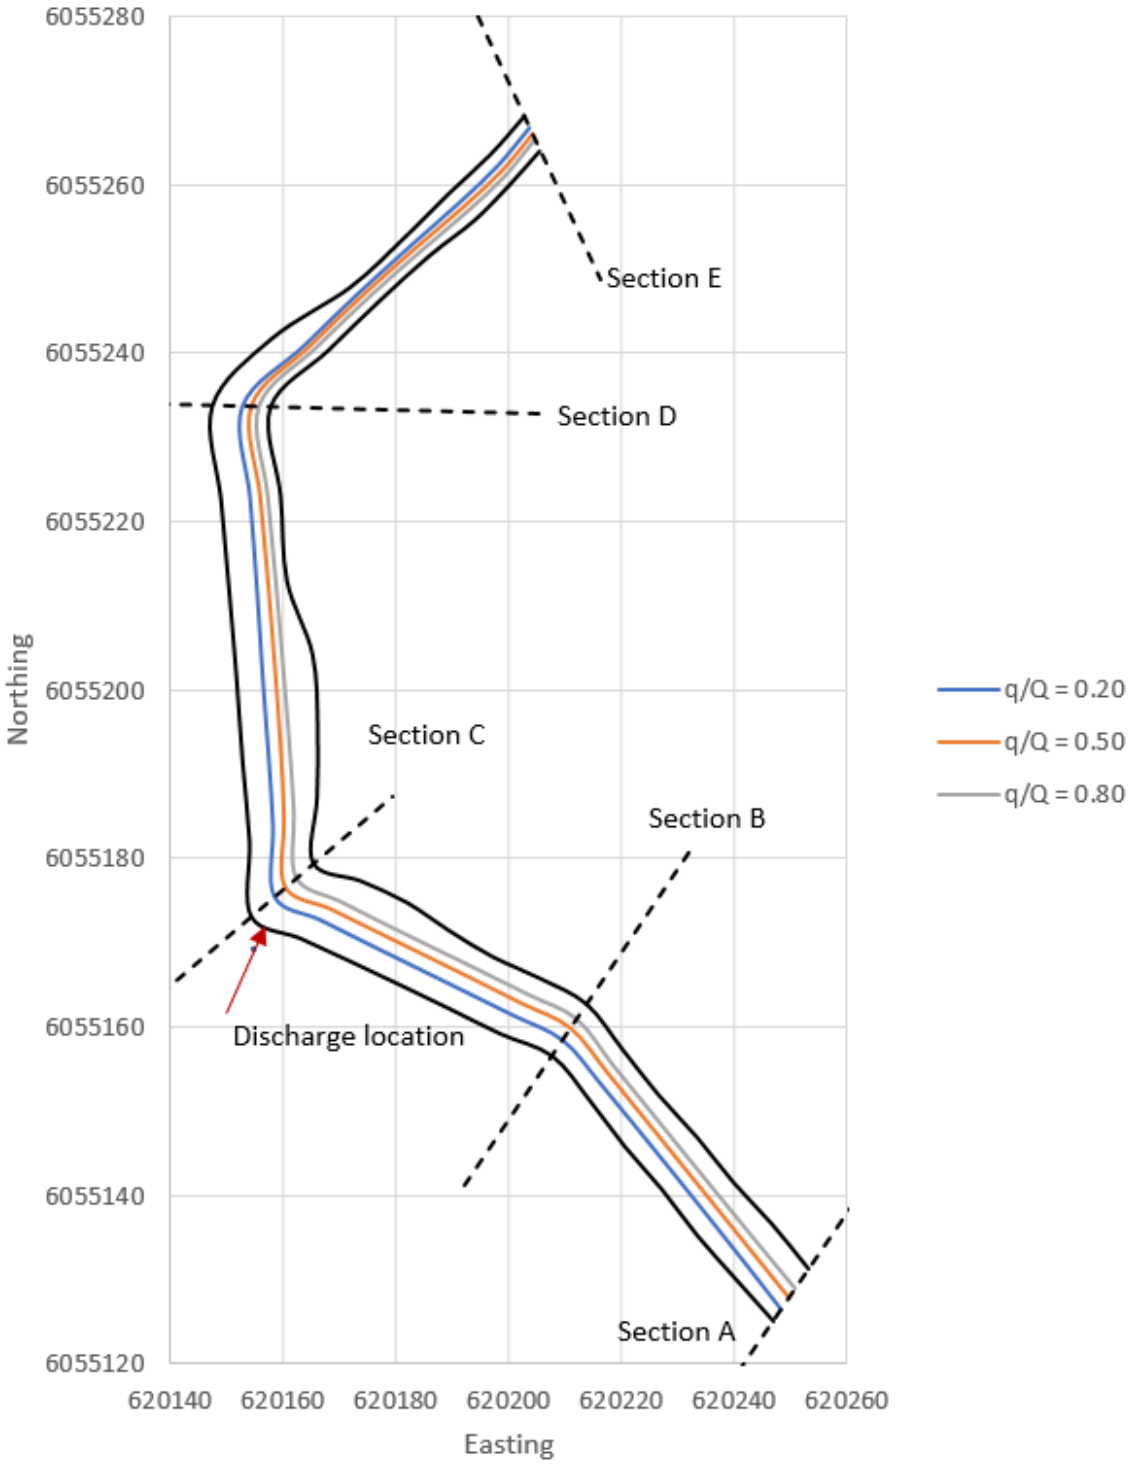

Figure 3-3. Illustration of cumulative discharge near the Goathorn Creek IDZ

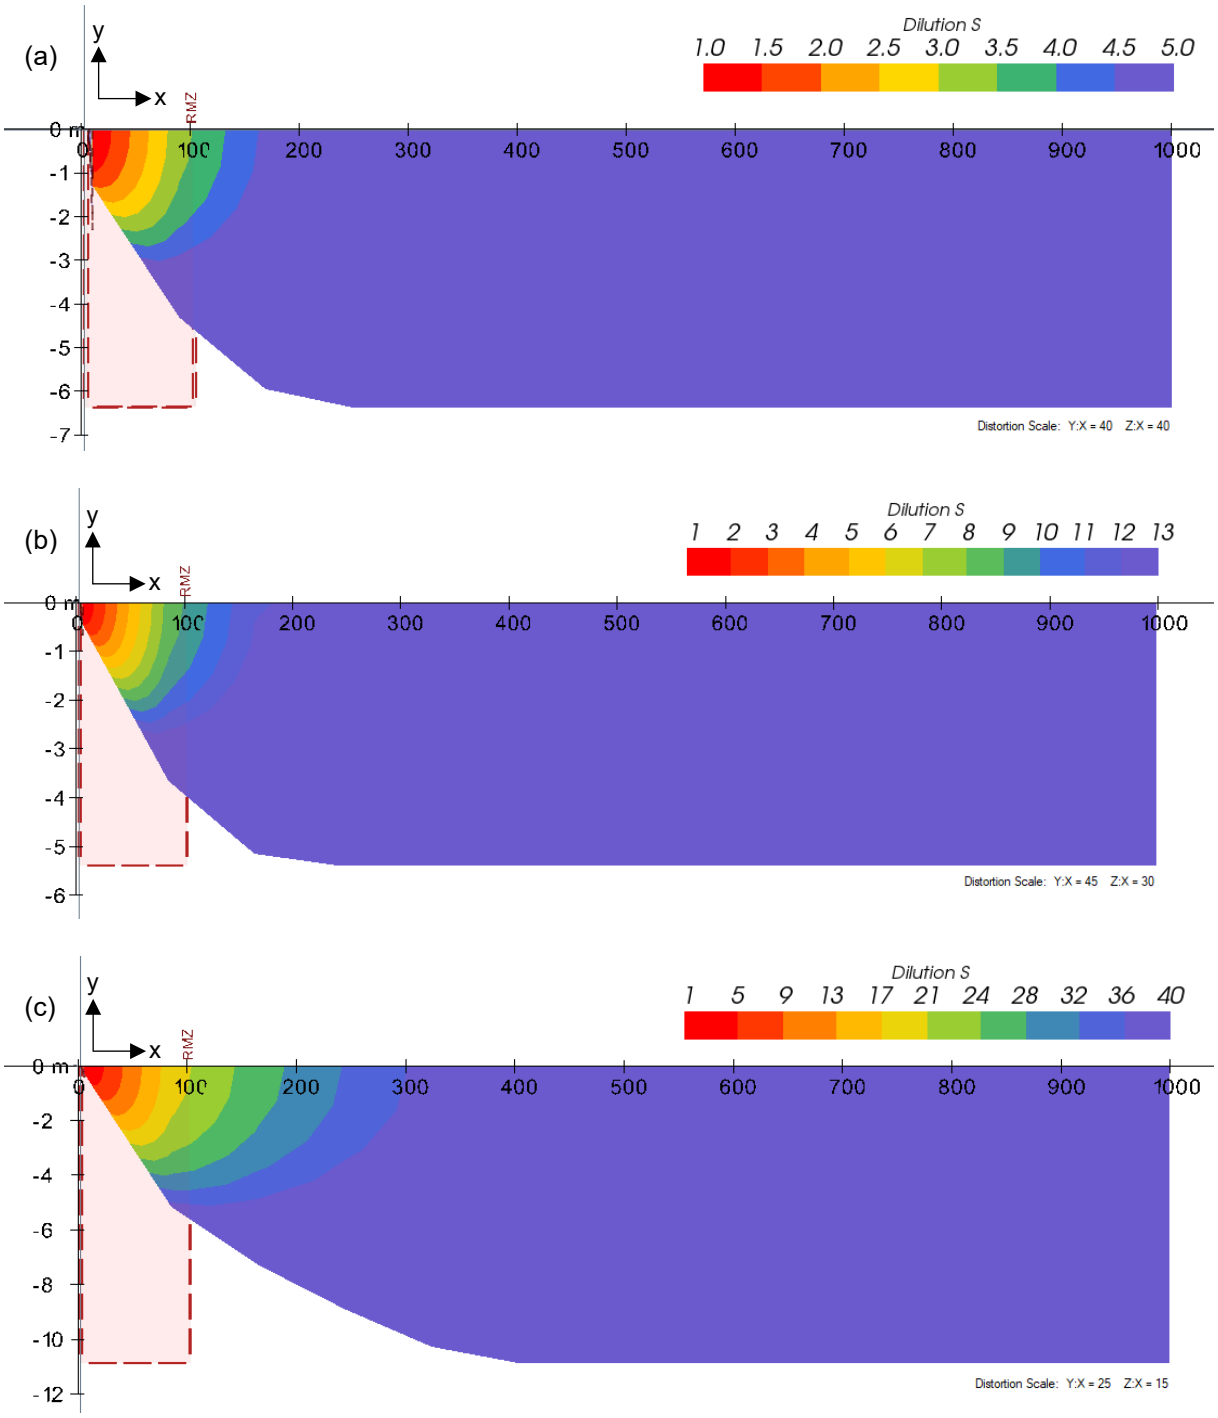
3.3 Mixing Model Description

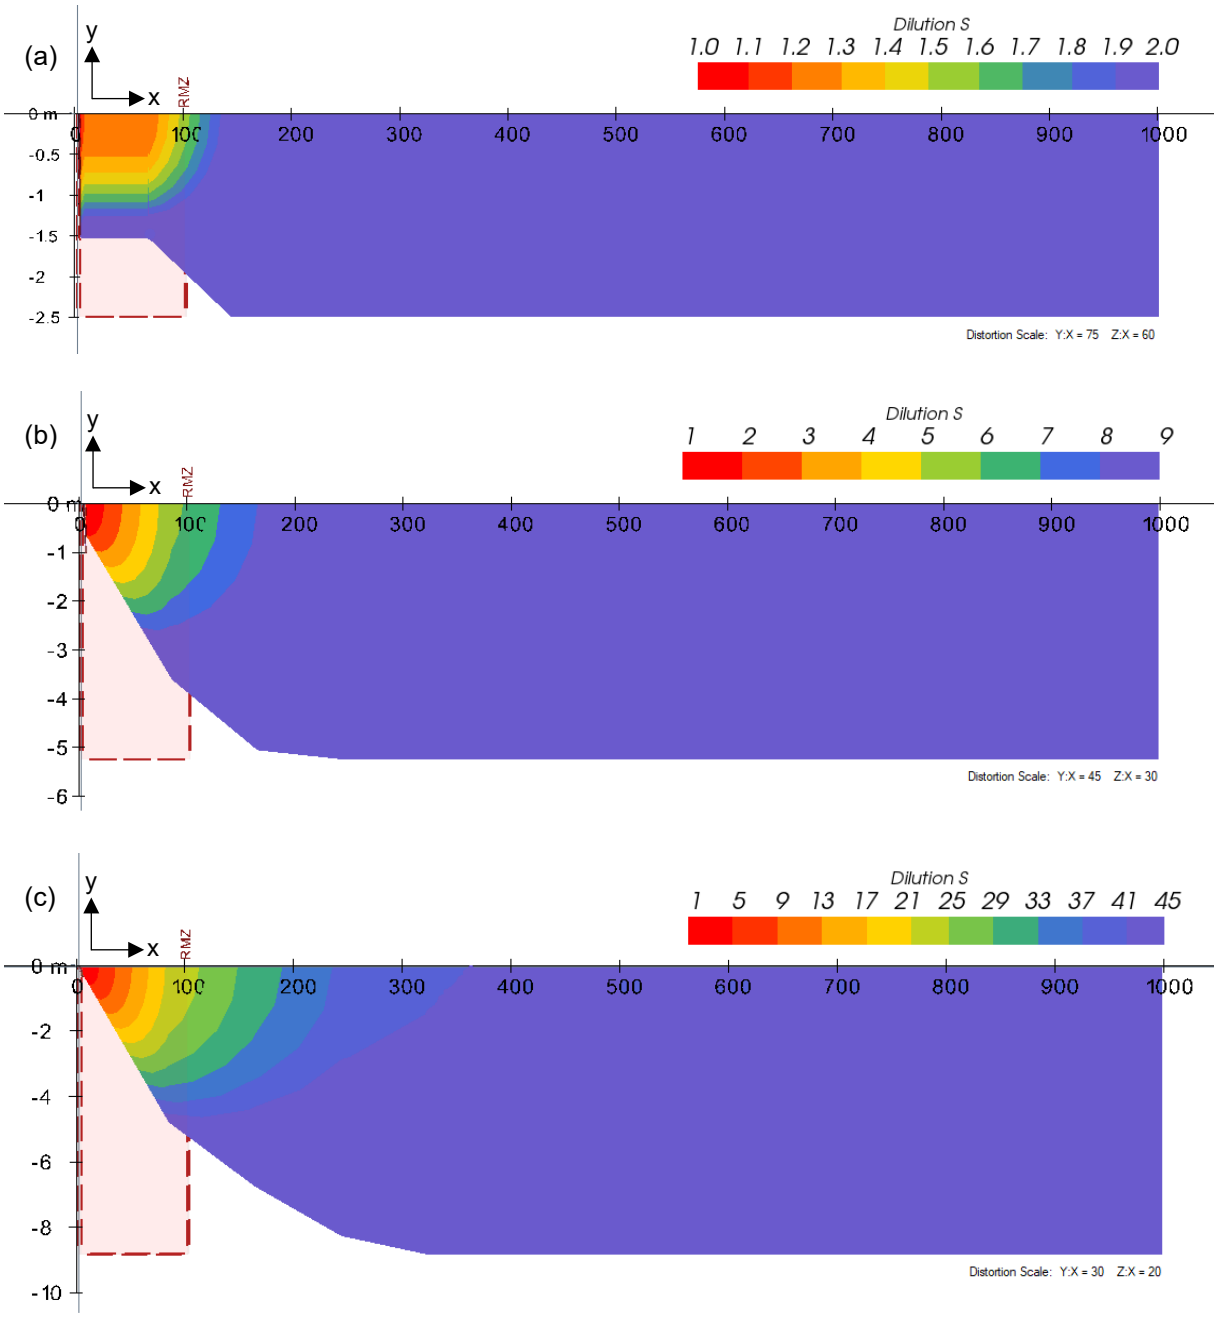
CORMIX employs jet integral model for near-field (Yotsukura and Sayre, 1976) and cumulative discharge method for far-field mixing processes (Doneker and Jirka, 2007). The program requires input on flow and discharge rate, hydraulic condition, simplified geometry of ambient and discharge channel, and water quality descriptions, among others.



For the IDZ cases evaluated in this study, the model was configured as a slightly meandering channel (conservative assumption) to represent the Goathorn Creek, with Manning's roughness coefficient obtained from the hydraulic modeling (Section 3.1). The model geometry for each IDZ case was schematized as a rectangular cross-section keeping the depth-velocity conditions consistent with hydraulics of the creek (refer to Table 3-1). For the tributary (discharging channel), it was assumed that the velocity is the same as the creek, and the depth at the discharge location is like the mean depth of creek flow. The model domain was extended up to 1.5 km downstream of the discharge location.

For water quality prediction, parameter concentrations were specified for the effluent discharge with consideration of background water quality in the creek. With the mixing models set for the worst, reasonable worst and expected cases, in-stream water quality was evaluated for each POC. Estimates of the effluent plume were obtained at various distances downstream of the discharge location, and across the transverse direction of the creek.

3.4 Dilution Characterization



The developed CORMIX model was used to predict water quality in the Goathorn Creek due to effluent discharge from the TCP (during the Operation phase) and the NMP (during the Post-closure phase). The model provided estimates of concentration change and corresponding dilution of the effluent plumes at downstream locations.

Figure 3-4 and Figure 3-5 illustrate dilution contours for the IDZ cases during the Operation and post-closure, respectively. The dilution (denoted as S) is defined as the effluent concentration (or initial concentration) over the concentration at a point resulting from mixing. Since CORMIX utilizes the 'cumulative discharge method', the transverse dimension illustrated in the figures represents relative width in terms of cumulative discharge across the creek. The actual width was obtained using the cumulative discharge distribution of the surveyed cross sections described in Section 3.2.

Source: NA CAPR002055 Telkwa Project General EA Support - IDZ update\MixingModeling

Figure 3-4. Model results showing dilution for the IDZ cases during the Operation phase – (a) worst case (S_{max} = 4.9), (b) reasonable worst case (S_{max} = 12.4), and (c) expected case (S_{max} = 39.6)

Source: NA CAPR002055 Telkwa Project General EA Support - IDZ update\MixingModeling

Figure 3-5. Model results showing dilution for the IDZ cases during the Post-closure phases – (a) worst case (1:1 flow ratio) (S_{max} = 2), (b) reasonable worst case (S_{max} = 8.3), and (c) expected case (S_{max} = 40.3)

As a result of turbulent mixing, the effluent plume is diluted downstream beyond the discharge location. The maximum dilution depends on the creek flow and the effluent discharge rate. Due to shallow depths, plumes become vertically well-mixed within shorter distances, and the dilution is governed by transverse mixing across channel width. The mixing coefficient for different cases varied from 0.014 to 0.05 m^2/s (Table 3-2), where the dimensionless mixing coefficient was about 0.5. This is a conservative estimate and falls within literature values. The dimensionless transverse mixing coefficients can vary from 0.3 to 0.6 for regular channels and 0.6 to 0.9 for gently meandering channels (Fischer et al. 1979; Rutherford 1994).

Table 3-2. Mixing model results for various cases

Parameter	Operation			Post Closure		
	Worst case	Reasonable worst case	Expected case	Worst case[1]	Reasonable worst case	Expected case
Goathorn Creek Flow (m^3/s)	1	0.4	2.86	0.12	0.4	1.69
Effluent Discharge Rate (m^3/s)	0.26	0.035	0.074	0.12	0.055	0.043
Total Flow (m^3/s)	1.26	0.44	2.93	0.24	0.46	1.73
Transverse Mixing Coefficient (m^2/s)	0.042	0.021	0.066	0.014	0.022	0.050
Limiting Dilution, S_{max} [2]	4.9	12.4	39.6	2.0	8.3	40.3
Complete Mixing Length, L_{mix} (m)	192	179	362	122	177	277

Source: NA CAPR002055 Telkwa Project General EA Support - IDZ update\MixingModeling\TelkwaIDZ_CORMIX_ModelResults_rev05_2025update.xlsm

Notes:

[1] Corresponds to the case with 1:1 flow ratio.

[2] Maximum possible dilution for a given flow condition.

Table 3-2 shows the model predicts that complete mixing during operation will be achieved at 192 m, 179 m, and 362 m downstream from the effluent source for the worst case, reasonable worst case and expected case, respectively. It remains in similar range for the reasonable worst case and expected case in post closure but reduces to 122 m for the worst case with 1:1 flow ratio. These results suggested that complete mixing is not achieved within the 100 m length from the discharge. However, background and discharge water quality must be included in the assessment to determine if concentrations are likely to be below the WQG at the edge of the mixing zone at 100 m, as discussed in Section 4.

4 Initial Dilution Zone Assessment

The mixing and dilution of Project discharge and corresponding effluent plume were delineated based on the CORMIX model developed for the Goathorn Creek and compared with TG11 guidance. POCs identified for the effluent discharge were considered for this assessment, as discussed in the following sections.

4.1 IDZ Delineation

Spatial extent of the IDZ and plume features such as the flow occupied within the IDZ, and its length and width were estimated for the three IDZ cases. As outlined in TG11, these dimensions can vary depending on site-specific factors. Because of the shallow configuration near the left banks of Goathorn Creek (Section 3.2), plume widths are typically higher for a given flow condition, and 40% of channel width was considered for IDZ delineation. This width corresponds to 25% of total flow at the discharge location (section C, Figure 3-2). Emphasis was placed upon the IDZ length and flow criteria for evaluation. Table 4-1 outlines the evaluation criteria for the Goathorn Creek IDZ.

Table 4-1. Evaluation criteria for IDZ delineation

IDZ Feature	Criterion	Reference / Remark
Length	100 m	TG11 (ENV 2019)
Flow	25% of total flow	TG11 (ENV 2019)
Width	40% of channel width	Based on site-specific condition guided by TG11 (Section 3.5.2)

4.2 IDZ Results for Operation

4.2.1 Fully Mixed Conditions

Water quality in the Goathorn was analyzed using the mixing model and considering instream flow and background water quality as well as effluent concentration and discharge rate from the TCP during operation. The model estimated change in concentration as the effluent is diluted downstream because of turbulent mixing. The identified POCs were modeled for each IDZ cases to estimate concentrations after complete mixing and compared with in-stream WQGs (Table 4-2). The results are summarized below:

- Fully mixed concentration of nitrite, cobalt and selenium exceeds the WQG for the worst case, but meets the guideline for the reasonable worst and expected cases,
- WQG is exceeded for dissolved copper in all cases due to high background concentration. Effluent concentrations for the IDZ cases are approximately equal or lower than the background level, and
- Other parameters meet the respective WQGs for all IDZ cases after fully mixed condition is achieved.

Table 4-2. Fully Mixed Concentrations of POCs in Goathorn Creek (Operation Phase)

Parameter	WQG (mg/L)	Fully Mixed Concentration (mg/L)		
		Worst case (L_{mix} = 192 m)	Reasonable worst case (L_{mix} = 179 m)	Expected case (L_{mix} = 362 m)
Nitrate	3	0.94	0.42	0.07
Nitrite	0.02	**0.021**	0.0084	0.0011
Sulfate	218	108	55	29
Aluminum, total	0.27	0.26	0.12	0.10
Cobalt, dissolved	0.00045	**0.00063**	0.00028	0.00010
Copper, dissolved	0.0013	**0.0020**[1]	**0.0014**[1]	**0.0014**[1]
Iron, total	1	0.52	0.20	0.12
Molybdenum, total	0.034	0.0077	0.0033	0.0009

Thallium, total	0.00003	0.000014	0.000009	0.000006
Zinc, dissolved	0.0074	0.0030	0.0021	0.0016

Source: NA CAPR002055 Telkwa Project General EA Support - IDZ update\MixingModeling\TelkwaIDZ_CORMIX_ModelResults_rev05_2025update.xlsm

Notes: **Orange Bolded** value represents exceedance with respect to the WQG.

[1] Exceedance resulted from high background baseline concentration in Goathorn Creek.

4.2.2 Mixing Zone Extent

The effluent concentration from the TCP and the Goathorn Creek background baseline water chemistries were applied to the mixing model to delineate IDZ for each POC, considering the dilution required to meet the corresponding WQG. The IDZ extent was defined as the area downstream of discharge beyond which the instream WQGs will be met. The modeled water quality of each POC and corresponding plume features (length and width of the mixing zone) in the Goathorn Creek was compared with the IDZ evaluation criteria (Table 4-1) based on TG11 guidance.

Figure 4-1 shows the delineated plumes (area with concentration higher than WQG) of the POCs for TCP discharge. The plume lines correspond to the lines where WQGs are met. The IDZ extent cannot be estimated for dissolved copper due to higher background baseline concentration than the WQG. IDZ criteria based on TG11 guidance are exceeded in the Operation phase for the following parameters:

- Worst case: Aluminum
- Reasonable worst case: Selenium

Table 4-3 compares the results of the IDZ delineation for each POC against the TG11 criteria for IDZ length, fraction of flow occupied and its width. For the worst case, nitrite, cobalt and selenium do not meet WQG after complete mixing. The maximum IDZ length is 128 m which corresponds to aluminum plume. Nitrite, cobalt and aluminum meet IDZ criteria for the reasonable worst case, but the maximum IDZ length extends to 153 m to meet instream selenium WQG. All parameters meet the TG11 guidance for the expected case.

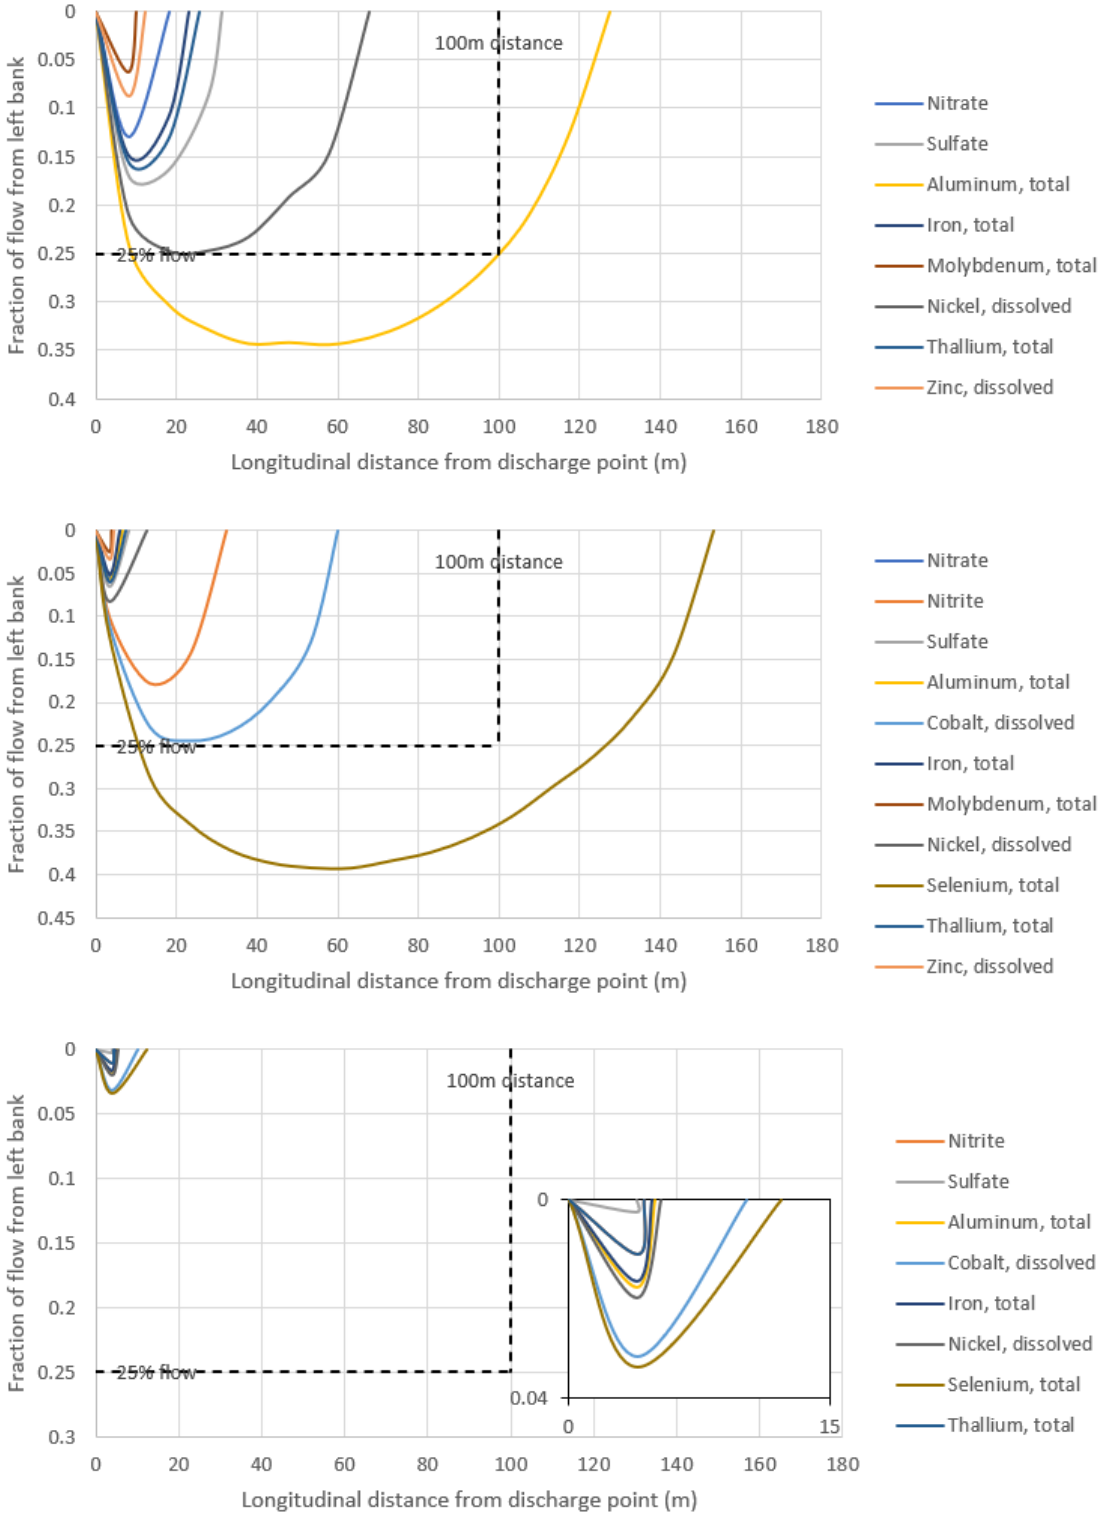

Figure 4-1. Plume delineation of POCs during the Operation phase – (a) worst case, (b) reasonable worst case, and (c) expected case

Table 4-3. IDZ Delineation Results for TCP Discharge in the Operation phase

Parameter	Scenario	WQG (mg/L)	Background concentration (mg/L)	Effluent concentration (mg/L)	IDZ length (m)	IDZ flow (% of stream)	IDZ width (% of stream)

Notes: n.a. refers to not applicable when effluent concentration is equal or below the WQG.
* Effluent concentration considers discharge from sewage treatment plant.

4.3 IDZ Results for the Post-closure Phase

4.3.1 Fully Mixed Conditions

Fully mixed conditions in Goathorn Creek during the Post-closure phase was modeled for the IDZ cases, using instream flow and background quality as well as effluent concentration and discharge rate from the NMP. For the worst case, both the unrealistic (0.4:1 ratio of creek flow to effluent discharge rate) and the conservative realistic worst case scenario (1:1 flow ratio) were evaluated for comparison (Table 4-4).

Comparison of the fully mixed concentrations of the POCs against WQGs showed parameters met their respective WQG for the IDZ cases during the Post-closure phase, except for aluminum and selenium for the worst case. WQG is also exceeded for cobalt and iron in the worst case at 0.4:1 flow ratio, but this condition is not realistic and unlikely to occur. Like the Operation phase, the fully mixed concentration of dissolved copper is higher than WQG due to elevated background baseline concentration.

Table 4-4. Fully Mixed Concentration of POCs in Goathorn Creek (Post-closure)

Parameter	WQG (mg/L)	Fully Mixed Concentration (mg/L)			
		Worst case (0.4: 1)[1]	Worst case (1:1)[1] (L_{mix} = 122 m)	Reasonable worst (L_{mix} = 177 m)	Expected case (L_{mix} = 277 m)
Nitrate	3	0.64	0.46	0.14	0.05
Nitrite	0.02	0.015	0.010	0.003	0.001
Sulfate	218	166.5	125.5	47.7	28.1
Aluminum, total	0.27	**0.34**	**0.31**	0.13	0.10
Cobalt, dissolved	0.00045	**0.00051**	0.00037	0.00013	0.00006
Copper, dissolved	0.0013	**0.0022**[2]	**0.0022**[2]	**0.0015**[2]	**0.0014**[2]
Iron, total	1	**1.15**	0.89	0.26	0.12
Molybdenum, total	0.034	0.0056	0.0041	0.0013	0.0006
Nickel, dissolved	0.0022	0.0016	0.0012	0.0005	0.0003
Selenium, total	0.002	**0.0058**	**0.0041**	0.0010	0.0002
Thallium, total	0.00003	0.000013	0.000011	0.000006	0.000005
Zinc, dissolved	0.0074	0.0017	0.0017	0.0015	0.0015

Source: NA CAPR002055 Telkwa Project General EA Support - IDZ update\MixingModeling\TelkwaIDZ_CORMIX_ModelResults_rev05_2025update.xlsm

Notes: **Orange Bolded** value represents exceedance with respect to the WQG

[1] Corresponds to ratio of Goathorn Creek flow to effluent discharge rate.

[2] Exceedance resulted from high background baseline concentration in Goathorn Creek.

4.3.2 Mixing Zone Extent

For discharge from the North Management Pond during/after closure, POCs including nitrate, nitrite, total molybdenum, dissolved nickel, total thallium and dissolved zinc do not register an IDZ, as the effluent concentrations are below the corresponding WQGs for the IDZ cases. The IDZ extent cannot be

estimated for dissolved copper due to it having a higher background baseline concentration than the WQG.

POCs with IDZ in Post-closure phase, along with plume delineation, are illustrated in Figure 4-2. Among these parameters, iron and cobalt exceeds the flow criteria (IDZ flow > 25%) for the worst case, but the extent remains within the 100 m guidance value based on TG11 criteria. These parameters meet the guidance for the reasonable and expected cases. Sulfate, aluminum and selenium also meet the IDZ criteria for these cases.

Table 4-5 compares the results of the IDZ delineation for each POC against the TG11 criteria after closure. For the worst case, aluminum and selenium do not meet WQG after complete mixing, and maximum IDZ length is 95 m which corresponds to iron plume. The maximum IDZ extent for the reasonable worst case is 44 m based on selenium WQG requirement.

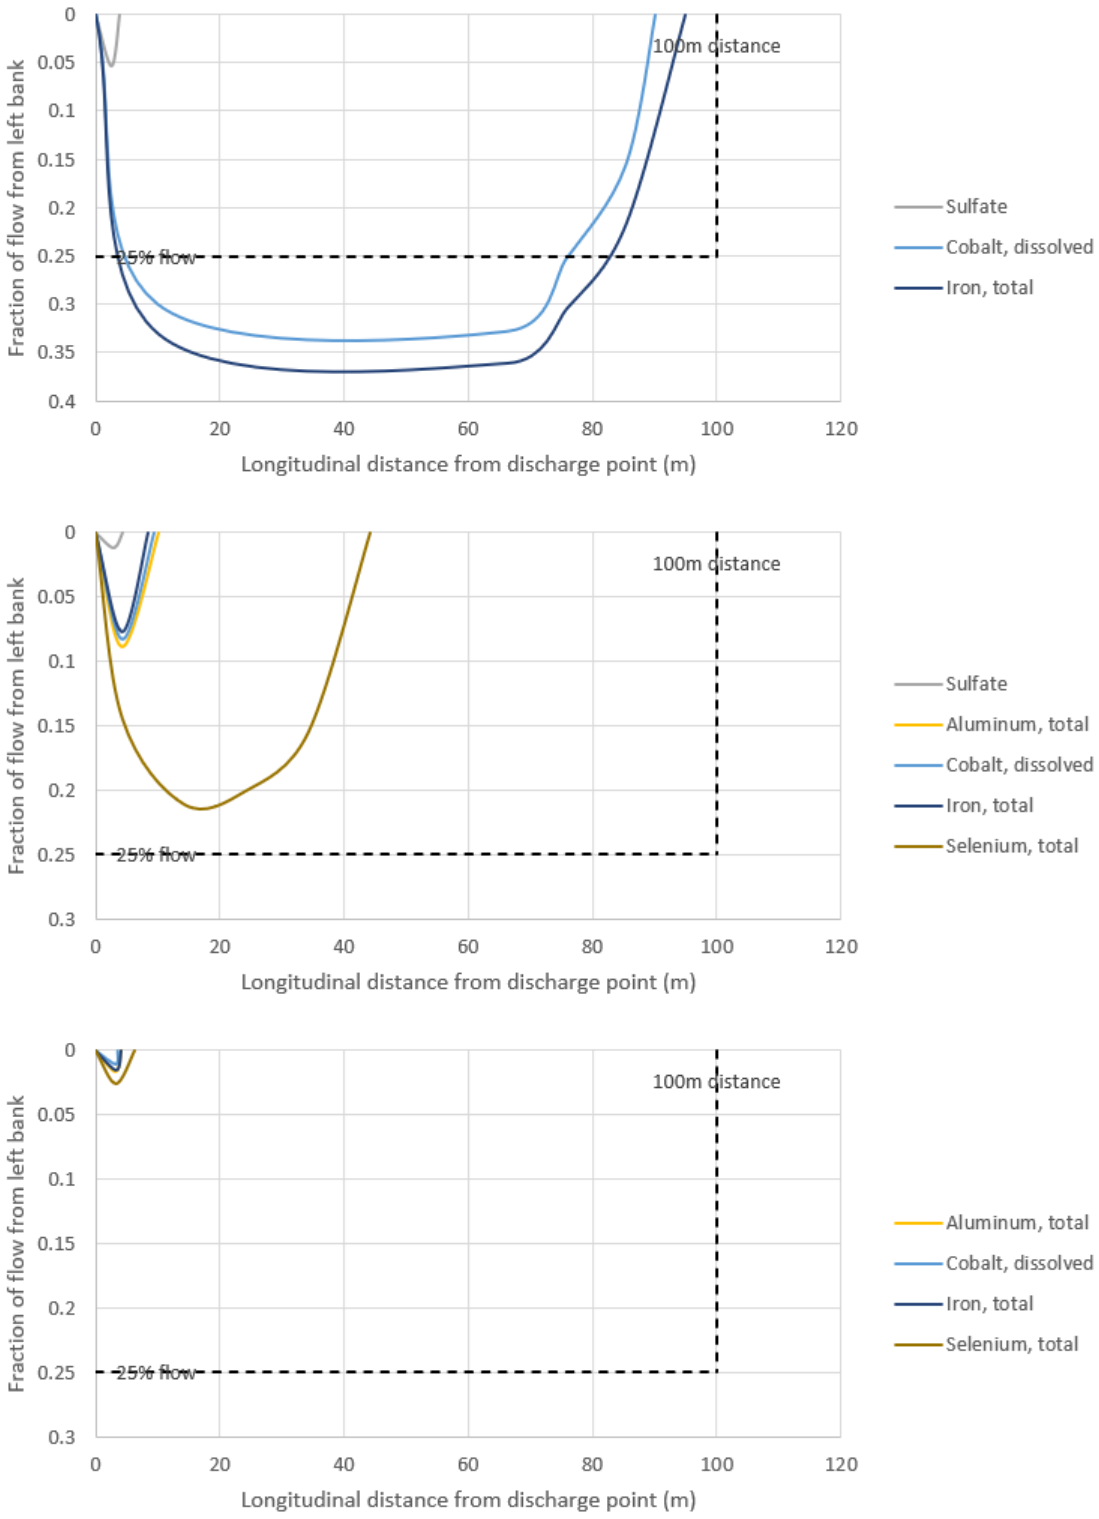

Figure 4-2. Plume delineation of POCs during post closure – (a) worst case (1:1 flow ratio), (b) reasonable worst case, and (c) expected case

Table 4-5. IDZ Delineation Results for NMP discharge after closure

Notes: n.a. refers to not applicable when effluent concentration is equal or below WQG

4.4 Evaluation of Results

BC provincial regulations recognize that dilution can play a role in mitigating the effects of effluents, and that an accepted area of higher concentrations of parameters can be present in an IDZ prior to full mixing. Evaluation of the IDZ cases based on BC's TG11 guidance indicated that, during the worst-case scenario, Goathorn Creek exceeds WQG: for nitrite, aluminum, cobalt and selenium during the Operation phase, and for aluminum and selenium during the Post-closure phase. It is important to note that the worst case is very conservative, as it considers the 7Q10 low flow combined with maximum discharge from the facility. It is unlikely water would need to be discharged from the Project during such a dry period. A WLB model run for 1-in-100-year dry event also confirmed that the discharge from the Project would be considerably lower than the modelled maximum discharge from the Project based on average hydrology condition.

A more realistic case is the reasonable worst case for which IDZ criteria to meet WQG is only exceeded for selenium during the Operation phase. The IDZ criteria is also exceeded for dissolved copper for all cases due to higher background baseline concentration compared to the WQG. POCs with exceedances for the reasonable worst case are discussed below:

Dissolved copper: Background concentration of dissolved copper is higher than the WQG of 0.0013 mg/L, with 50th percentile and 75th percentile concentrations of 0.021 and 0.014 mg/L, respectively. This results in no dilution capacity available in the Goathorn Creek. Although the effluent concentration during the Operation and Post-closure phases is higher than the WQG (except for the expected case during the Operation phase), the concentration is approximately equal to the creek's background baseline level after mixing (Table 4-6), and therefore the baseline water quality is not further deteriorated.

Table 4-6. Evaluation of Dissolved Copper Concentrations for the IDZ Cases

IDZ Case	WQG (mg/L)	Background Concentration (mg/L)	Operation		Post-Closure	
			Effluent Concentration (mg/L)	Fully Mixed Concentration (mg/L)	Effluent Concentration (mg/L)	Fully Mixed Concentration (mg/L)
Worst case	0.0013	0.0021	0.0015	0.0020	0.0022	0.0022
Reasonable worst	0.0013	0.0014	0.0015	0.0014	0.0022	0.0015
Expected case	0.0013	0.0014	0.0011	0.0014	0.0017	0.0014

Source: NA CAPR002055 Telkwa Project General EA Support - IDZ update\MixingModeling\TelkwaIDZ_CORMIX_ModelResults_rev05_2025update.xlsm

Total selenium: The IDZ criteria based on TG11 guidance is exceeded for total selenium for the reasonable worst case during the Operation phase, with an IDZ length of 153 m and the plume occupying 39% of the creek's flow (Table 4-3). The reasonable worst case scenario combines conservative conditions in both effluent quality (maximum concentration) and Goathorn Creek flows (7Q10 low-flow). The IDZ reduces to only 12 m for the expected case during the Operation phase. TG11 guidance is also met for the reasonable worst case and expected case after closure (Table 4-5).

5 Conclusions

The Goathorn Creek IDZ assessment was carried out following the TG11 guidance, produced by the BC Ministry of Environment and Parks. The assessment considers Tenas Project discharge during operation and after closure, with discharge from TCP and NMP, respectively. To characterize and delineate the extent of IDZ, three credible and conservative cases were considered, based on site-specific information:

- a worst case (very worst condition)
- a reasonable worst case (a worst case that could potentially occur)
- an expected case (case corresponding to typical conditions)

The IDZ assessment was carried out for POCs identified by the BAT assessment for the Project. The following parameters were identified as POCs: nitrate, nitrite, sulphate, aluminum (total), cobalt (dissolved), copper (dissolved), iron (total), nickel (dissolved), thallium (total), zinc (dissolved), molybdenum (total) and selenium (total).

Hydrodynamic mixing modeling was conducted to evaluate the IDZ extent for POCs for the worst, reasonable worst and expected cases and compared against TG11 guidance. For the worst case, Goathorn Creek exceeds WQG for aluminum, cobalt, nitrite, and selenium during the Operation phase, and for aluminum and selenium during the Post-closure phase. The worst case is very conservative and unlikely to occur during very dry periods as the Project will not be discharging. Emphasis was placed upon the reasonable worst case and the expected case, which are conservative but provides realistic evaluation scenario. The results are summarized below.

During the Operation Phase:

- IDZ criteria to meet applicable WQGs are satisfied for nitrate, nitrite, sulphate, aluminum, cobalt, iron, nickel, thallium, zinc, and molybdenum for the reasonable worst and expected cases.
- The IDZ extent of selenium exceeds the TG11 recommended length of 100 m for the reasonable worst case but meets the instream WQG further downstream. The IDZ criteria of 100 m is met for the expected case.
- WQG is exceeded for dissolved copper due to background baseline concentration higher than the WQG, but the effluent concentration reaches background concentration after complete mixing.
- The maximum length of IDZ is 153 m and 12 m for the reasonable worst and expected cases, respectively (based on selenium).

During the Post-closure Phase:

- POCs including nitrate, nitrite, molybdenum, nickel, thallium, and zinc do not register an IDZ, as their effluent concentrations are below the corresponding WQGs for the IDZ cases.
- IDZ criteria based on TG11 guidance is met for sulfate, aluminum, cobalt, iron, and selenium for the reasonable worst and expected cases. The guidance is exceeded for dissolved copper with background baseline concentration higher than the WQG but remains close to the background level after complete mixing.

- The maximum length of IDZ is 44 m and 6 m for the reasonable worst and expected cases, respectively (based on selenium).

5.1 Limitations and Recommendations

- This IDZ assessment has been prepared based on the information available at the time of study. The assessment should be updated if any changes in the baseline conditions or modelled effluent discharge projections are expected.
- The CORMIX modeling work was carried out using geometry based on field measured cross sections. Uncertainty exists in the mixing and IDZ lengths presented herein, as the model does not account local variations (rapids, flow around cobbles and boulders) that impacts mixing. It is suggested to confirm the mixing zone lengths through field monitoring and tracer study program, particularly during low flow period.

Subject	Liner Seepage Assessment and Preliminary Cost Estimate for Tenas Management Ponds – **REV01**
Client	Telkwa Coal Ltd.
Project	2CT025.008.0300 (CAPR002055)

1 Introduction

Telkwa Coal Ltd. (TCL) has retained SRK Consulting (Canada) Inc. (SRK) to design and provide a cost estimate for a liner system that will reduce seepage rates from the Tenas Management Ponds to below allowable thresholds defined in SRK's site water balance (SRK, 2020a). This liner assessment was initially conducted on four liner alternatives in the preliminary seepage assessment (Section 4.4.1); based on the performance and estimated costs, one of these liner alternatives was advanced to a focused seepage assessment (Section 4.4.2).

This memo is divided into sections describing the Liner Design, Seepage Modeling, Cost Estimate, and Recommendations. The *Liner Design* section provides background on the seepage design criteria from SRK's site water balance, geometry of the various management ponds, and details the various liner materials and liner system configurations. The *Seepage Modeling* section details the cross sections that serve as a basis for the seepage models, the assumptions and calibration of these models, and presents the results of the seepage assessment. The *Cost Estimate* section outlines the assumptions and methodologies used as a basis for the cost estimate and presents the estimated cost for each of the various liner configurations. The memo concludes with the *Recommendations* section, presenting SRK's recommended liner option and path forward.

This technical memo was initially submitted in December 2020. The cost estimate was updated in this revision with updates indicated with blue text.

2 Background

The Tenas Project is in central British Columbia, approximately 15 km south of Smithers and 2 km southwest of Telkwa. The Project site is located south of the Tenas River and the boundaries of the project encompass the lower reaches of the Telkwa River, Goathorn Creek, and Pine Creek. The Tenas Project's total mine life is anticipated to be 22 years, including one year of pre-stripping and construction followed by 21 years of production. The mine plan was designed and scheduled in a manner that allows potentially-acid generating (PAG) rock to be deposited into management ponds (MP), including the East Management Pond (EMP), West Management Pond (WMP), and North Management Pond (NMP). These MP are above-ground PAG rock storage facilitates. The WMP consists of a portion that is an excavated pit (*Tenas Pit Phase 9*), referred to herein as '*In Pit*', and the remaining portion outside the pit referred to herein as '*Ex Pit*'.

Environmental containment is to be achieved with liner systems that are constructed along the bottom of the ponds and the upstream slopes of the perimeter dams.

3 Liner Design

The following subsections describe the seepage design criteria, pond geometry, material properties, and liner configurations.

3.1 Seepage Design Criteria

A preliminary water balance provided design targets for the liner seepage analyses that evaluated seepage rates through the bottom of the MP and upstream slopes of the perimeter dams. The maximum allowable seepage through the MP catchments was determined to be 2,800 m^3/day from the site wide water balance (SRKa, 2020). This value represents the maximum seepage rate allowed to maintain a positive water balance over the PAG rock (e.g. maintain a minimum 1 m capping of ponded water).

This value is conservatively based on the "*10 Year Dry*" scenario. For the average year scenario, the allowable seepage rate through the management pond catchments increases to 4,260 m^3/day. For reference, the water quality target from the Definitive Feasibility Study (DFS) model was 1,700 m^3/day.

3.2 Pond Geometry and Potential Seepage Areas

Design elevations for the dam crests, freeboard, and areas pertinent to the seepage assessments are included in Table 1. Design revision 1 includes added capacity to account for the reduction in MP storage capacity due to the incorporation of a 1 m thick soil over-liner as the liner protective component (discussed in Section 4.4.2). This revision included raising the dam crests and freeboard elevations for the EMP, NMP, and WMP (Ex-Pit).

Table 1: Model Geometry for the TCL Management Ponds

Design Revision	Management Pond	Area Pond[1] (m^2)	Area Upstream Dam Slopes[1] (m^2)	Cumulative Area[1] (m^2)	Dam Crest Elev. (masl)	Freeboard Elev. (masl)
0	EMP	901,000	163,000	1,064,000	850	849
	WMP (Ex Pit)	371,600	122,000	493,600	850	849

	WMP (Ex Pit)	361,874	141,148	503,022	852	851
	WMP (In Pit)	533,548	n/a	533,548	n/a	n/a
	NMP	210,190	83,017	293,207	831	830

Notes:

[1] MP surfaces areas contributing to seepage through the liner system.

[2] Model geometry for Design Revision 1 provided by Telkwa on November 17, 2020.

3.3 Material Properties

Table 2 lists the materials that were modeled in the seepage assessment for the various liner design options. The high case for the native soils represents an increase of the base case hydraulic conductivities by a factor of 2.7 (SRK, 2020b).

Table 2: Materials Considered for the Liner Seepage Assessment

Material	Hydraulic Conductivity, k (m/s)	
	Base Case	High Case
Native soil (EMP)[1]	3.0E-6	8.1E-6
Native soil (NMP)[1]	1.9E-6	5.1E-6
Bentonite[2]	5.0E-11	-
Soil-bentonite mixture[2]	1.0E-9	-
Soil-bentonite mixture (optimized)[2]	1.0E-10	-
Skilhorn clay[3]	5.9E-9	-
Clay-bentonite mixture[2]	8.6E-10	-
Skeena Sedimentary Rock[4]	3.62E-7	-

Notes:

[1] Values for native soil derived from calibration with the site wide FEFLOW® groundwater model.

[2] Values for bentonite, soil-bentonite mixtures, and clay-bentonite mixtures assumed based on experience with previous projects.

[3] Values for Skilhorn measured in laboratory falling head hydraulic conductivity testing performed with a flexible wall permeameter.

[4] Values for Skeena sedimentary rock (bedrock) obtained from FEFLOW® groundwater model.

A hydraulic conductivity of 1.0E-9 m/s for the soil-bentonite mixture was calculated based an assumed hydraulic conductivity for bentonite of 5E-11 m/s. However, recent laboratory testing performed by Golder Associates on available bentonite are showing the hydraulic conductivity to be 3E-12 m/s. The calculated hydraulic conductivity of the soil-bentonite mixture, using the recent lab test value, equates to 6E-11 m/s. Based on the lab data and previous experience with a similar northern project, it is anticipated that a hydraulic conductivity value of 1E-10 m/s can be achieved and was therefore considered in the liner option assessment as an optimized value.

4 Model Development

Two-dimensional liner seepage analyses were carried out with GeoStudio's SEEP/W modeling software (Version 11.0.1.21429). The following subsections detail the cross-sections, model assumptions and calibration, and results of the seepage assessment.

4.1 Cross Sections

The cross sections shown in Figure 1 were developed into seepage models for the NMP, EMP, and WMP based on site topography, bedrock elevations, and perimeter dam designs. These cross sections were chosen along alignments that intersect the lowest topography in each pond as well as nearby creeks (*topographic lows*). Section 1 (1'-1') was used to develop the model for the NMP; Section 2 (2'-2') was used to develop the model for the EMP; and Sections 3 (3'-3') and 4 (4'-4') were used to develop models for the WMP.

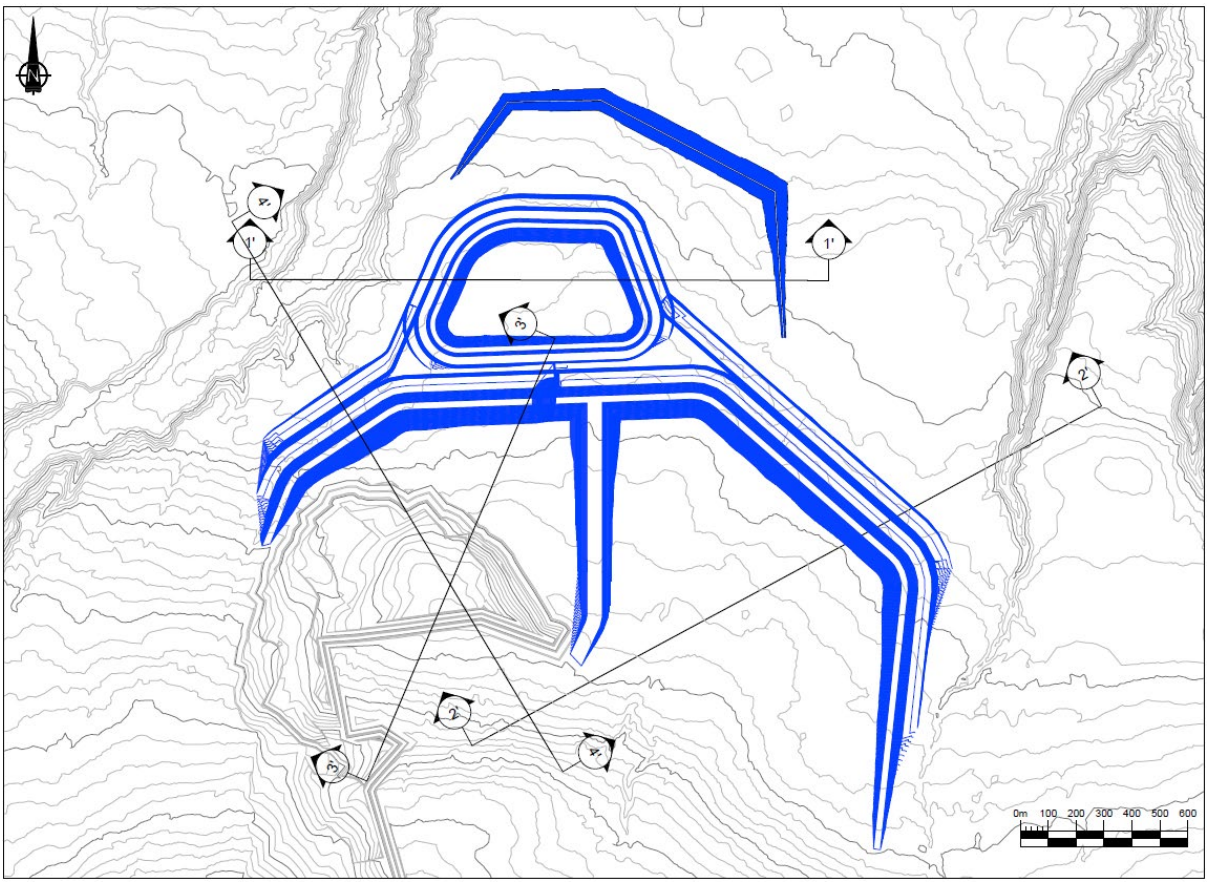

Figure 1: Cross sections of the North Management Pond (Section 1'-1'), the East Management Pond (Section 2'-2'), and the West Management Pond (Sections 3'-3' and 4'-4') that served as the basis for the seepage models

4.2 Model Assumptions

The seepage models for the EMP, WMP, and NMP were developed based on cross sections that included the site topography, bedrock elevations, and designs of the perimeter dams. For the preliminary seepage assessment only Section 1 for the NMP and Section 2 for the EMP were evaluated. At this early stage, seepage through the WMP was assumed to be equivalent to seepage through the EMP.

The seepage assessment for revision 1 included two additional sections for the WMP that spanned the *In Pit* and *Ex Pit* portions. Seepage through unlined portions of the WMP *In Pit* were determined using FEFLOW® groundwater modeling software by applying a total head of 851 masl (*the dam freeboard elevation*). The WMP *In Pit* portion is assumed to be graded at 2.5H:1V from the *Ex Pit* portion towards the south-southwest. This produces a portion of the north slope that is comprised of overburden and a portion that is a bedrock pit wall. Scenarios that involve lining the overburden slope and bedrock pit wall are discussed in Section 4.4.

Seepage models developed for the preliminary and revision 1 seepage assessments consider the uppermost soil layer to be unsaturated and the underlying soil (below the estimated water table) to be saturated.

4.3 Calibration

The site wide groundwater model was developed with FEFLOW® groundwater modeling software. This model utilized data from recent and historic drilling campaigns to distribute the native ground in the vicinity of the MP into *Silty Clay* and *Sand & Gravel*, with hydraulic conductivities of 2E-7 and 3E-6 m/s, respectively. These materials were used as a basis to calibrate the two-dimensional liner seepage models.

To accomplish this calibration, the hydraulic conductivity of the materials in the unlined two-dimensional seepage models were toggled until the seepage rates matched the rates measured with FEFLOW®. For the purposes of this calibration, the resulting material at the EMP and WMP were *Sand & Gravel*, with a hydraulic conductivity of 3E-6 m/s, and the material at the NMP was 40% *Clay* and 60% *Sand & Gravel,* with a hydraulic conductivity of 1.88E-6 m/s.

4.4 Liner Configurations

Four liner configurations were modeled as part of the preliminary seepage assessment (Design Revision 0) and one of these configurations was advanced to the focused seepage assessment (Design Revision 1).

4.4.1 Preliminary Seepage Assessment (Design Revision 0)

The liner options that were modeled in the two-dimensional SEEP/W (2020) for the preliminary seepage assessment are listed below:

1. Native soil with bentonite disked into the surface at 0.15 or 0.30 m.
2. Clay from Skilhorn Quarry placed to a depth of 1 to 2 m.
3. Clay from Skilhorn Quarry placed to a depth of 1 m with bentonite disked to a depth of 0.15 or 0.30 m.
4. Bentonite placed to a thickness of 0.15 or 0.30 m and covered with a minimum 0.15 m of native soil.

4.4.2 Focused Seepage Assessment (Design Revision 1)

The soil-bentonite liner system was progressed to a focused liner seepage assessment in 0.15 and 0.30 m thicknesses with the optimized bentonite hydraulic conductivity of 1E-10 m/s. Table 3 presents the various configurations of the soil-bentonite liner system that were assessed.

Each configuration considers the WMP *Ex Pit* portion to be lined. Configurations 1 to 4 consider the overburden pit slope of the WMP *In Pit* portion to be lined. Configurations 5 to 8 consider the entire

WMP *In Pit* portion to be lined other than the subvertical bedrock cliff; this includes a 1.5 m thick layer *In Pit* soil liner overlying the bedrock. These configurations were modeled with the base and high case hydraulic conductivity values listed in Table 2.

Table 3: Soil-Bentonite Liner Systems Assessed as Part of the Focused Seepage Modeling

Configuration	Case	SB Thickness (m)	NMP	EMP	WMP Liner Configurations		
					OVB Slope Liner	In-Pit Liner	BR Pit Wall Slope Liner
1	BC	0.15	Y	Y	Y	N	N
2	BC	0.30	Y	Y	Y	N	N
3	HC	0.15	Y	Y	Y	N	N
4	HC	0.30	Y	Y	Y	N	N
5	BC	0.15	Y	Y	Y	Y	Y
6	HC	0.15	Y	Y	Y	Y	Y
7	BC	0.30	Y	Y	Y	Y	Y
8	HC	0.30	Y	Y	Y	Y	Y

Notes:

[1] BC = Base Case; HC = High Case; MP = Management Pond; BR = Bedrock; OVB = Overburden; SB = Soil-Bentonite

[2] For the High Case, the hydraulic conductivity of the underlying soils has been increased by a factor of 2.7.

[3] The Soil-Bentonite material assumes an optimized hydraulic conductivity of 1E-10 m/s.

5 Seepage Results

Seepage rates were quantified through the surface areas corresponding to the upstream perimeter dam slopes and MP pond bottoms. Results of the preliminary seepage modeling (Design Revision 0) are presented in Section 5.1 and results of the focused seepage modeling (Design Revision 1) are presented in Section 5.2.

5.1 Results of the Preliminary Seepage Modeling (Design Revision 0)

Preliminary seepage modeling was conducted with the geometry shown in Table 1 for *Design Revision 0.* Only Section 1 for the NMP and Section 2 for the EMP were modeled at this stage and the *In Pit* portion of the WMP was not independently assessed. Based on FEFLOW® groundwater modeling, with a scenario considering a 0.5 m thick compacted clay liner, the seepage from the *Ex Pit* portion of the WMP would be 483 m^3/day. This seepage rate was factored into the seepage results calculated for the various liner systems with SEEP/W (2020).

Results of the two-dimensional liner seepage assessment are shown in Table 4 and plotted in Figure 2. Seven liner alternatives provided a seepage rate < 2,800 m^3/day, which corresponds to the maximum allowable seepage rate for the *10 Year Dry* scenario. Four of these alternatives barely met the design criteria. However, the design criteria was easily achieved for bentonite placed to a thickness of 0.15 or

0.30 m covered with a minimum 0.15 m of native soil, and the optimized native soil with bentonite disked into the surface at 0.15 m (soil-bentonite). Each of the liner alternatives listed below provide a seepage rate ≤ 4,260 m^3/day, which corresponds to the *Average Year* scenario.

Table 4: Results from the Two-dimensional Liner Seepage Assessment for the Various Liner Configurations Modeled in SEEP/W

Model	Seepage (m^3/day)	Seepage < 2800 m^3/day (Y/N)
No Liner	6,992	N
0.15m Soil-Bentonite	3,226	N
0.15m Soil-Bentonite (Optimized)	1,606	Y
0.3m Soil-Bentonite	2,779	Y
1m Skilhorn Clay	3,201	N
2m Skilhorn Clay	2,779	Y
1m Skilhorn Clay + 0.15m Clay-Bentonite	2,788	Y
1m Skilhorn Clay + 0.30m Clay-Bentonite	2,580	Y
0.15m Bentonite	1,204	Y
0.30m Bentonite	843	Y

Notes:

[1] Seepage limit based on the 10 Year Dry scenario developed in the site water balance is 2,800 m^3/day.

[2] Seepage limit based on the Average Year scenario developed in the site water balance is 4,260 m^3/day.

Results of the two-dimensional liner seepage assessment are plotted in Figure 2.

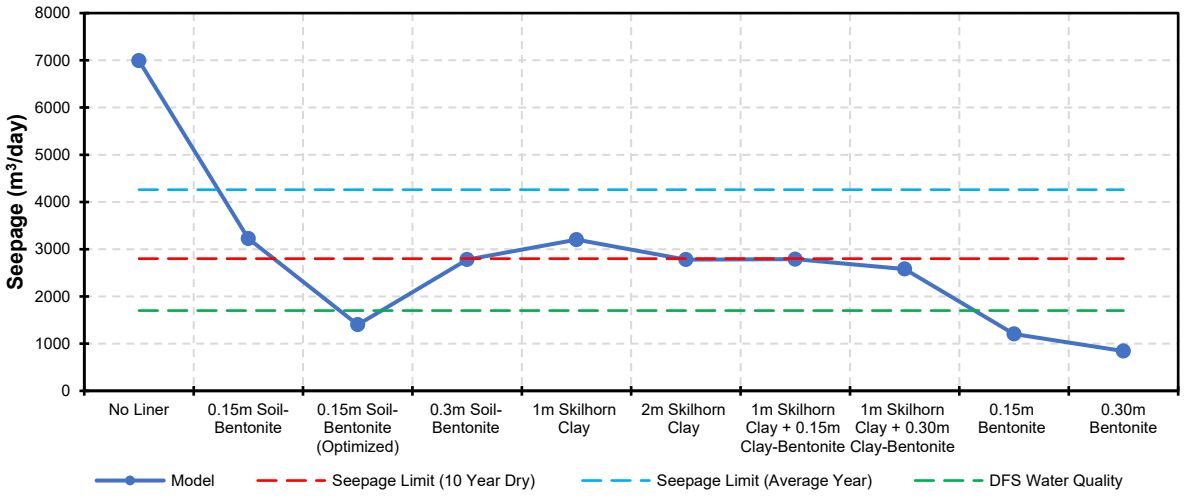

Figure 2: Results of the Preliminary Liner Seepage Assessment (Design Revision 0) for the Various Liner Configurations Modeled in SEEP/W

From these scenarios, the 0.15 m soil-bentonite liner system with the optimized bentonite hydraulic conductivity of 1E-10 m/s was advanced to the focused seepage modeling (Design Revision 1). The alternatives for the 0.15 m and 0.30 m pure bentonite were not advanced due to the costs being significantly higher compared to the other liner systems (see Section 6.3.2).

5.2 Results of the Focused Seepage Modeling (Design Revision 1)

The 0.15 m soil-bentonite liner system with the optimized bentonite hydraulic conductivity of 1E-10 m/s was subjected to a more detailed assessment as part of the focused seepage modeling (Design Revision 1). An additional 0.30 m soil-bentonite liner system with the optimized bentonite hydraulic conductivity of 1E-10 m/s was also incorporated into the focused seepage modeling. These seepage models were developed with the geometry shown in Table 1 for *Design Revision 1*.

5.2.1 WMP Liner Assessment

For the focused seepage modeling, two cross sections were modeled for the WMP (Section 3 and Section 4), in addition to the sections for the NMP and EMP. The new cross sections spanned the WMP *In Pit* and *Ex Pit* portions.

The results of the focused seepage assessment for all MPs with the geometry shown in Table 1 for *Design Revision 1* are listed in Table 5 and shown in Figure 3. The seepage rates for the WMP *In Pit* and *Ex Pit* portions are the average of Sections 3 and 4. As noted in Section 4.4.2, Configurations 1 to 4 consider the overburden pit slope of the WMP *In Pit* portion to be lined. Configurations 5 to 8 consider the entire WMP *In Pit* portion to be lined other than the subvertical bedrock cliff; this includes a 1.5 m thick layer *In Pit* soil liner overlying the bedrock to provide a bedding layer for the liner.

Table 5: Results of the Focused Liner Seepage Assessment for the NMP, EMP, and WMP *In Pit* and *Ex Pit* Conducted using the Geometry from Design Revision 1

Liner	Case	SB Thickness (m)	WMP Liner Configurations			Seepage Rates (m^3/day)				
			OVB Slope Liner	In-Pit Liner	BR Pit Wall Slope Liner	EMP	NMP	WMP (In-Pit)	WMP (Ex-Pit)	Cumulative
1	BC	0.15	Y	N	N	738	371	654	706	2470
2	BC	0.30	Y	N	N	458	198	701	379	1736
3	HC	0.15	Y	N	N	978	408	1441	778	3605
4	HC	0.30	Y	N	N	535	210	1445	404	2594
5	BC	0.15	Y	Y	Y	738	371	368	762	2239
6	HC	0.15	Y	Y	Y	978	408	567	933	2886
7	BC	0.30	Y	Y	Y	458	198	313	400	1369
8	HC	0.30	Y	Y	Y	535	210	447	523	1715

Notes:

[1] BC = Base Case; HC = High Case; MP = Management Pond; BR = Bedrock; OVB = Overburden; SB = Soil-Bentonite

[2] For the High Case, the hydraulic conductivity of the underlying soils has been increased by a factor of 2.7.

[3] The Soil-Bentonite material assumes an optimized hydraulic conductivity of 1E-10 m/s.

The results of the focused seepage assessment for all MPs with the geometry shown in Table 1 for *Design Revision 1* are shown in Figure 3.

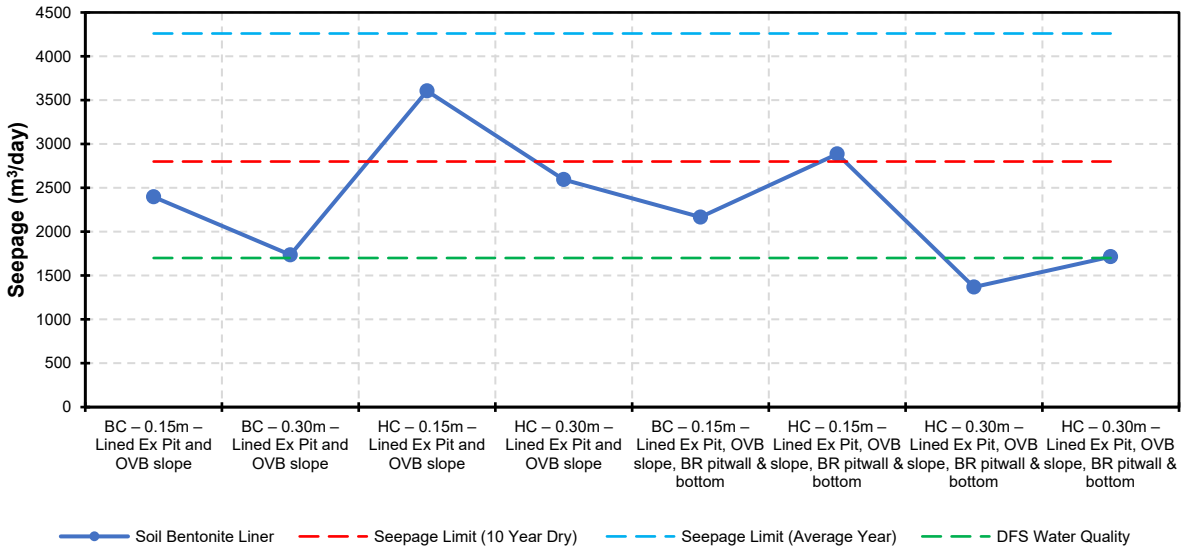

Figure 3: Results of the Focused Liner Seepage Assessment (Design Revision 1) for the Various Soil-bentonite Liner Configurations Modeled in SEEP/W

The 0.30 m soil-bentonite liner systems provide a seepage rate ≤ 2,800 m^3/day for both the base and high cases, which corresponds to the maximum allowable seepage rate for the *10 Year Dry* scenario. Each of the liner alternatives listed above provide a seepage rate ≤ 4,260 m^3/day, which corresponds to the *Average Year* scenario.

6 Cost Estimate

A screening level cost estimate for the various liner configurations was completed for the construction activities using RSMeans (2024) construction cost estimating software. The following subsections detail the assumptions and justifications, methodologies, and results of the cost estimation.

This cost estimate was completed as a high-level screening for liner options and is not detailed enough to provide accurate costs for construction. The liner costs do not include the liner for the *In Pit* portion of the WMP.

6.1 Assumptions

Table 6 lists the lined areas for the various MP that were considered in the cost estimates.

Table 6: Areas considered for the cost estimate for the various liner alternatives.

Design Revision[1]	Management Pond	Area Pond (m^2)	Area Upstream Dam Slopes (m^2)	Cumulative Area (m^2)
1	EMP	961,939	180,136	1,142,075
	WMP[2] (Ex Pit)	361,874	141,148	503,022
	NMP	210,190	83,017	293,207

Notes:
[1] Model geometry for Design Revision 1 provided by Telkwa on November 17, 2020.
[2] Lining of the WMP *In Pit* portion is not being considered in the cost estimate.

Numerous activities have been excluded that will be similar in all options:

- Clearing and grubbing of the MP areas.
- Stripping and stockpiling of topsoil.
- Stockpiling overburden from the pit for application as a 1 m thick soil over-liner.

The following assumptions were made to facilitate the cost estimate:

- Costs for hauling off-site materials to site are based on quoted rates provided by TCL.
- Costs for non-woven geotextile are based on quoted rates provided by TCL.
- Unit costs for construction activities derived using RSMeans (2024).
- Kamloops location assumed for crews, productivity, and contractor overheads and profits.
- Maintenance costs assumed to be 5% of overall costs.
- Quality Assurance / Quality Control assumed to be 10% of overall costs.
- Disking rates based on commercial agricultural rates.
- Bentonite dry density and unit weight derived from laboratory testing.

6.2 Methodologies

The following construction methodologies were considered to facilitate the cost estimation:

Option 1: Soil-bentonite (11% bentonite mixed into native soil)
Construction of the soil-bentonite liner alternative involves pre-disking the soil followed by the spreading and disking of bentonite into the native soil at a thickness of either 0.15 or 0.30 m. The maximum disking depth per pass is 0.15 m. Therefore, in the case of the 0.30 m soil-bentonite liner, a 0.15 m layer of local material will need to be added prior to the second addition of bentonite. Compaction will be accomplished with a smooth drum roller for each lift.

Option 2: Skilhorn clay liner

Construction of the Skilhorn clay liner alternative involves spreading the clay in 0.25 m lifts followed by compaction with a sheepsfoot roller to the target thickness of 1 or 2 m.

Option 3: Skilhorn clay liner + Clay-bentonite (1 m Skilhorn clay with 11% bentonite mixed into Skilhorn clay)
Construction of the Skilhorn clay liner alternative involves spreading the clay in 0.25 m lifts followed by compaction with a sheepsfoot roller to the target thickness of 1 m. Placement and disking of bentonite into the Skilhorn clay would be completed to a thickness of either 0.15 or 0.30 m as per the method described in Option 1.

Option 4: Bentonite (Pure bentonite blanket covered with 0.15 m of native soil)
Construction of the pure bentonite liner alternative involves foundation preparation being first undertaken by stripping and stockpiling of the native soil. Bentonite is spread to the target thickness of 0.15 to 0.30 m followed by compaction with a smooth drum roller. Subsequent placement of a 0.15 m soil over-liner is followed by compaction with a smooth drum roller.

6.2.1 Protective Component

Prior to placement of PAG material, the 0.15 to 0.30 m soil-bentonite or pure bentonite liner systems (Options 1 & 4) will require a protective component to protect the liners from being punctured by large waste rock, which could damage the integrity and functionality of the liner system. Two options were evaluated for this protective layer:

1. Placement of a 1 m thick over-liner layer of locally stockpiled soil followed by compaction with a smooth drum roller.
2. Deployment of a 16 oz. non-woven geotextile.

6.3 Cost Estimate Results for Lined Management Pond Areas

6.3.1 Cost Estimate for Protective Component

The following costs have been estimated for the protective component:

- $13,900,000 for material costs, placement, and compaction of a 0.5 m over-liner layer of locally stockpiled soil.

The cost for these protective components must be applied to the cost 0.15 to 0.30 m soil-bentonite and pure bentonite liner systems listed in Table 7.

6.3.2 Cost Estimate for Liner Systems

The results of the cost estimate for the various liner configurations are listed in Table 7. Note that the cost of the 0.5 m soil over-liner protective component is factored into the cost estimate for the 0.15 and 0.30 m soil-bentonite and pure bentonite liner systems.

Table 7: Cost Estimate for the Various Liner Configurations Assessed as Part of the Liner Seepage Assessment

Model	Cost ($)	Cost ($/m² of Lined Area)
0.15 m Soil-Bentonite	$ 38,600,000	$ 15
0.30 m Soil-Bentonite	$ 65,000,000	$ 30
1.0 m Skilhorn Clay + 0.15 m Clay-Bentonite	$ 95,600,000	$ 38
1.0 m Skilhorn Clay + 0.30 m Clay-Bentonite	$ 114,600,000	$ 45
1.0 m Skilhorn Clay	$ 76,600,000	$ 31
2.0 m Skilhorn Clay	$ 153,100,000	$ 62
0.15 m Bentonite	$ 189,300,000	$ 72
0.30 m Bentonite	$ 372,300,000	$ 142

The results of the cost estimate for the various liner configurations are plotted in Figure 4. Note that the options for 2 m Skilhorn clay and 0.15 to 0.30 m thick bentonite blanket were not included in the figure due to the cost being significantly higher than the other options shown.

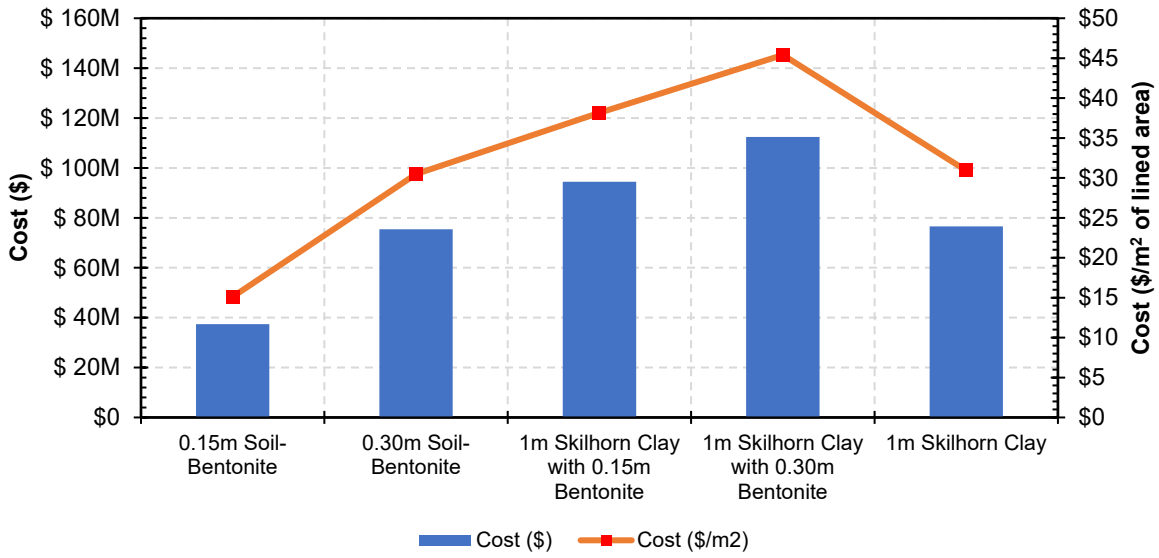

Figure 4: Estimated Costs for a Selection of the Various Liner Systems Assessed in the Liner Seepage Assessment.

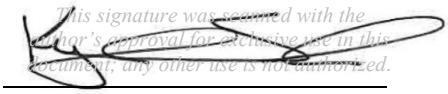
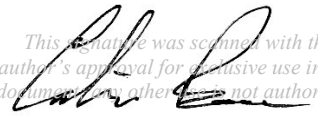
7 Recommendations



- A 0.30 m soil-bentonite liner system with a hydraulic conductivity of 1E-10 m/s would be sufficient to reduce total seepage below the 2,800 m^3/day design criteria target for both the base and high cases.
- A protective layer of 0.5 m of protective soil over-liner should be placed on top of the liner.
- To perform a laboratory study to determine the optimal proportion of bentonite-soil blend to produce a soil-bentonite mixture with a hydraulic conductivity ≤ 1E-10 m/s. This was completed and is documented in SRK (2024).
- Design assumptions at this stage of the project were preliminary and should be revised and updated as required in the next stage of design.

Closure



This memo, “Liner seepage assessment and preliminary cost estimate for Tenas Management Ponds”, was prepared by SRK Consulting (Canada) Inc. to provide recommendations for a liner system that will reduce seepage rates from the Tenas Management Ponds to below allowable thresholds defined in SRK’s site water balance (SRK, 2020a).

We trust the information included meets your present requirements. If you have any questions regarding the analyses or if you require additional information, please do not hesitate to contact the undersigned.

Notes:

(1) Lined areas utilized in the cost estimate for the various liner alternatives provided in Table 6 in the memo *Liner seepage assessment and preliminary cost estimate for Tenas Management Ponds*

(2) Tonneage of bentonite calculated by multiplying the lined area by the percentage of bentonite, thickness of bentonite layer, and dry density.

Executive Summary

As part of the Tenas Project Environmental Assessment, SRK Consulting (Canada) Inc. (SRK) was retained by Telkwa Mining Ltd (TCM) to complete a hydrometeorological analysis for the Tenas Project (the Project).

The Project is located approximately 25 km southwest of the town of Smithers, BC within the Telkwa River watershed and is composed of an open pit, backfill, external stockpiles, water management ponds, control ponds, process plant and rail load out.

This report presents the hydrometeorological baseline of the Project. The key objective of this report is to to develop inputs to the Project water management plan and water and load balance model.

Site hydrometeorological conditions are monitored via a site weather station and five (5) hydrometric stations located on each of the major watercourses (Goathorn-Hydro, Telkwa-Hydro, Tenas-Hydro/Tenas-Hydro B, and Four-Hydro). The weather station was operated from 2017 to 2022. Hydrometric stations have two to three complete hydrologic years of data recorded within the 2017 to 2022 period. For this assessment, the relatively short site datasets are supplemented with regional datasets and climate re-analysis models.

Synthetic long-term Project climate datasets were developed based on transposing the regional datasets at Smithers Airport to the site and adjusting for observed orographic effects. These datasets were used to derive Project design parameters and water and load balance inputs, as well as to support development of a rainfall-runoff model. This model was developed and calibrated for each of the local hydrometric stations. A combination of the calibrated models from Goathorn Creek and Tenas Creek were applied to the Tenas Project area.

Selected climate parameters are summarized in Table 0-1 to Table 0-3.

Table 0-1: Derived Monthly and Annual Project Climate Normals

Parameter	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
Average Temperature (°C)[1]	-9.2	-6.1	-2.7	2.1	6.8	10.7	13.0	12.5	8.4	2.6	-3.8	-7.9	2.2

Mean annual runoff for the Project was determined to be 219 mm/year with an annual runoff coefficient of 0.36 with the highest flows occurring in May and June due to freshet, and low flows occurring during the winter.

Climate change scenarios for RCP4.5, RCP6.5 and RCP8.5 were evaluated for the Project Area. The effects of the RCP4.5 scenario were used to generate mean annual and monthly temperature and precipitation correction factors, which also affect runoff and evaporation rates, as summarized in Table 0-4.

Table 0-4: Projected Climate Change Impacts on Selected Climate Parameters

Timeframe	Mean Annual Temperature (°C)	Mean Annual Precipitation (mm)	Mean Annual Evaporation (mm)
2011-2040	1.2°C	+5%	+2%
2041-2070	2.4°C	+12%	+4%
2071-2100	3.0°C	+15%	+5%

Source: Compiled in text from R code \\srk.ad\dfs\na\van\Projects\01_SITES\Telkwa Coal\1CT027.003_2020 EA Water Management\200_Meteorology_Update\Rwork\Climate_Change_rev03.Rmd

Extreme precipitation magnitudes are expected to increase. Monthly streamflow is expected to experience an overall increase in flow magnitude and a shift to an earlier spring freshet. No significant trend in peak flows is projected.

The short duration of the Project meteorological and hydrometric datasets is a limitation of this hydrometeorological baseline report. SRK recommends ongoing monitoring of Project meteorologic conditions, and continued hydrometric station monitoring at Four-Hydro and Tenas-Hydro B as a minimum.This report should be updated when additional data become available. In particular, the Four-Hydro discharge record requires additional flow measurements to characterize baseline conditions for effects assessments and to support predictive modelling.

1 Introduction

SRK Consulting (Canada) Inc. has been tasked with updating the meteorological and hydrological characterization to develop inputs required for the Tenas Project (the Project) in support of the Environmental Assessment (EA).

The following report provides an updated summary of baseline meteorology and hydrology data collected between 2017 and 2022. Regional records were used to extend the local records in order to develop statistical climate and hydrologic parameters that will be used to support various technical studies for the EA, including water management designs, groundwater modeling, and the water and load balance model. The main changes pertain to the updating of the synthetic climate record based on additional data from the local station since the development of the EA baseline report (SRK 2022) and the hydrological parameters based on new calibration to the available data.

1.1 Project Setting

The Tenas Coal Project is a proposed coal mine located in the Coast Mountains of the Cordilleran Region near the Town of Telkwa approximately 25 km southwest of Smithers, British Columbia. The coal preparation plant, maintenance facilities and service facilities would be located approximately 6 km southwest of Telkwa. The Project footprint elevation ranges from 750 to 1050 meters above sea level (masl) with a median elevation of 800 masl. The Ministry of Environment and Climate Change Strategy (MECCS) have published hydrological zones that represent areas of homogeneous hydrologic and geomorphic characteristics. The Tenas Project is within Zone 8 – Nechako Plateau.

The Project encompasses the lower reaches of the Telkwa River, Tenas Creek, Goathorn Creek and Four Creek. The Telkwa River is a major tributary to the Bulkley River near the village of Telkwa, British Columbia, which ultimately flows into the Skeena River. Four Creek is a tributary of Goathorn Creek, and Goathorn Creek and Tenas Creek are tributaries of the Telkwa River.

Figure 1-1 shows the Project location.

1.2 Scope of Report

Meteorology and hydrology studies conducted as part of the Telkwa Coal Project Prefeasibility studies (SRK 2017a, 2017b) identified gaps in the existing meteorological and hydrological datasets. Site specific hydrometeorological data started being collected in 2017. The first years of records (2017-2019) were used by SRK to develop a hydrometeorological baseline for the site (SRK, 2022). Project data collection continued between 2020 and 2022. These new records were incorporated into the hydrometeorological analysis to support Project advancement in 2022 and are documented in this report.

This report is an update to the the baseline Project climate and hydrology previously developed by SRK (SRK, 2022) and generates projections of future climate conditions. This update includes available data up to October 2023.

- Section 2 presents the available meteorological datasets (2017-2022)
- Section 3 presents the available hydrometric datasets (2017-2022)
- Section 4 describes how available datasets were used to develop the Project Area meteorology and hydrometric synthetic time series
- Section 5 outlines how climate change impacts on Project air temperature, precipitation, lake evaporation and streamflow were evaluated from 2022 onwards.

2 Baseline Meteorology

2.1 Section Overview

Meteorological characteristics are typically assessed by integrating Project-specific and regional meteorology records as well as comparing previous studies related to the Project and regional indices. Placing the Project-specific parameters in context using regional analyses is important to be able to provide meteorological inputs to the Project based on extended periods of record.

2.2 Available Meteorological Data

Baseline meteorological monitoring was initiated at the Telkwa Coal Project site in September 2017 by ERM Consultants.

This section summarizes the available monitoring data for the Telkwa Coal Project. Regional climate data from the surrounding area has also been assessed to place the Telkwa Coal Project climate into context.

2.2.1 Project Data

Baseline climate data for the Project Area was collected at the Tenas Deposit automatic weather station (54.59° N, 127.19° W), installed on 29 September 2017 and operated through September 2022. Figure 2-1 illustrates the location of the Tenas Deposit Station and Table 2-1 provides the metadata.

The monitoring record from the Tenas Deposit Station was compiled, reviewed, and validated by ERM (ERM 2019). The following data is recorded at the weather station:

- Hourly average wind speed
- Hourly wind direction and standard deviation of wind direction for 2017
- Hourly average air temperature
- Hourly average relative humidity
- Hourly average solar radiation
- Hourly average barometric pressure
- Hourly sampled snow depth
- 5-minute and hourly accumulated total precipitation

Details concerning the meteorological station configuration, data collection and preliminary gap-filling procedures are outlined in Section 4 of The Tenas Project 2017 to 2019 Baseline Report (ERM 2019).

2.2.2 Regional Data

Regional meteorological data for British Columbia is available from private as well as provincial and federal government sources. Regional re-analysis products for historical climate and future scenarios are available as gridded products developed by third parties based on government

datasets. Within the Nechako Plateau hydrological zone, there are over 90 regional meteorological stations monitored by the Meteorological Service of Canada (MSC). This division of Environment and Climate Change Canada provides public historical meteorological data and information.

Figure 2-1 illustrates the locations of selected regional meteorological stations with respect to the Project. Three stations have historically operated in the town of Smithers. Smithers Airport Auto and Smithers A are understood to be the same station, after an upgrade in 2018. Table 2-1 presents the metadata for the selected regional stations.

Table 2-1: Regional Meteorological Station Selections

Station Name	Climate Identifier	Latitude [° N]	Longitude [° W]	Elevation [masl]	Record Start	Record End	Distance from Project [km]
QUICK	1076638	54.62	126.90	533	1962	1995	19.1

Note: Smithers A and Smithers Airport Auto are located at the same geographic location.

2.2.3 Missing Data

The meteorological records from the Tenas Deposit Station have low amount of absent records with nearly 100% of records available for precipitation and air temperature (maximum, minimum, and daily averages). Higher quantity of missing records were found for solar radiation - mostly during the winter, presumably because of snow cover – and pan evaporation. The missing records and data availability are provided in Figure 2-2 for all measured variables.

Figure 2-2: Site meteorological records availability

Source: compiled from R code SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html

Note: Total data availability is presented after the variable name in parenthesis. Abbreviations have the following measing, ir row-wise order: evap = Pan Evaporation, gust = Wind Gust, prcp = Precipitation, rain = Rainfall, rh = Relative Humidity, snow = Snowfall, snowpack = Snowpack, ssrd = Shortwave Solar Radiation, tavg = Average Daily Temperature, tmax = Maximum Daily Temperature, tmin = Minimum Daily Temperature, ws = Wind Speed.

In terms of regional datasets, most stations also present some gaps in their records. Based on the correlations between stations these gaps could be patched appropriately as described in the sections below. Figure 2-3 and Figure 2-4 present the number of days with mean temperature and precipitation records respectively available at each regional station from 1942 to 2023. The color ramp on the right-hand side indicates 0 days of data (white) to a full 366 days (dark blue).

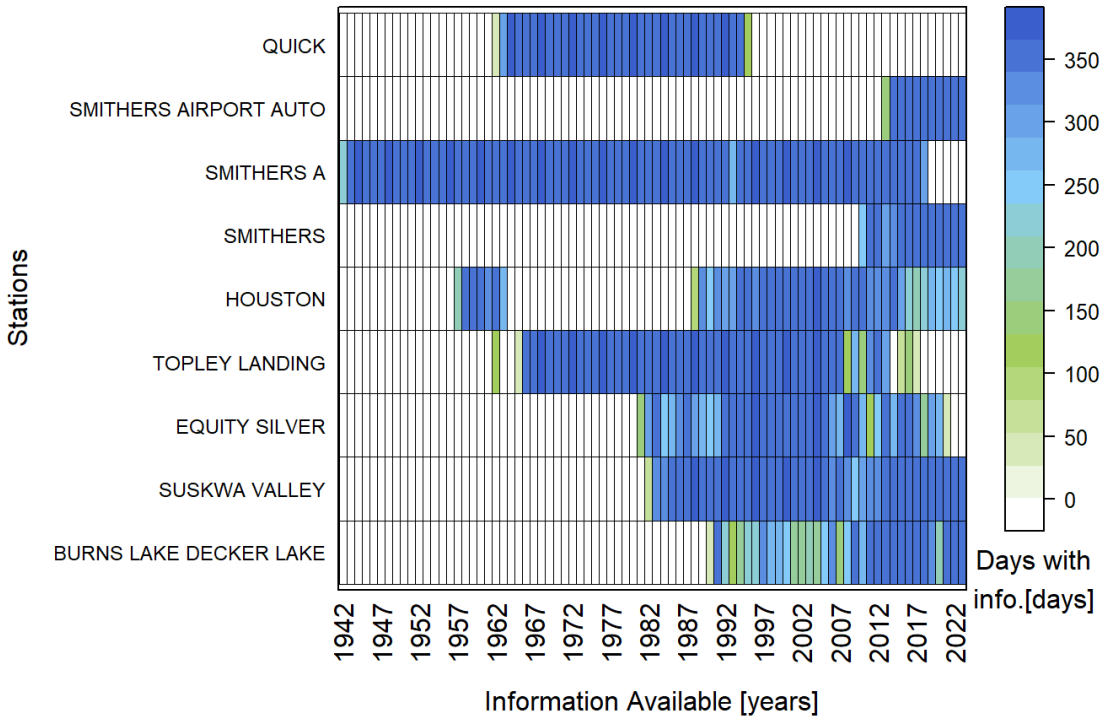

Figure 2-3: Number of Days with Mean Temperature Data Available Every Year from Regional Stations

2.2.4 Regional Snow Datasets

The British Columbia Snow Survey Data includes datasets from two regional networks:

The Automated Snow Weather Station (ASWS) network is comprised of stations operated by the Ministry of Environment, BC Hydro and others. These stations collect hourly snow water equivalent, snow depth, air temperature, and precipitation. Data is available in near-real-time. Tsai Creek Station is the closest station of this type to the Project and is published by the Ministry of Environment and Climate Change Strategy (MECCS, 2020).

The Manual Snow Survey Sites network is operated by the province of British Columbia and manually measures snow depth and snow water equivalent. Measurements are taken monthly when snow is present, providing a record of snowpack across the province. Hudson Bay is the closest manual survey site to the Project. This data is also published by MECCS (2019).

Figure 2-5 illustrates the locations of Tsai Creek and Hudson Bay snow survey stations, and Table 2-2 presents details pertaining to these stations.

Table 2-2: Regional Snow Survey Stations

Station Name	Station Identifier	Latitude [°]	Longitude [°]	Elevation [masl]	Record Start	Record End	Distance from Project [km]
Tsai Creek	4B17P	54.64	-127.68	1360	2003	Current	31.8
Hudson Bay	4B03A	54.76	-127.27	1480	1972	Current	19.4

2.2.5 Reanalysis Meteorological Datasets

Reanalysis products were used to calculate regional orographic trends for precipitation and temperature. The regional stations could not account for these orographic trends, particularly in winter due to inversions present at some stations, and Project data did not produce a meaningful relationship to regional stations due to its relatively short duration of record.

Climate reanalysis combines gridded global models with observed historical data to produce historical climate and to incorporate adjustments based on developed relationships. Multiple reanalysis datasets are available in different spatiotemporal resolutions. Table 2-3 presents the three reanalysis datasets examined for this study.

Table 2-3: Overview of Reanalysis Datasets Examined in this Study

Reanalysis	Institution	Period of Record
ERA-5 (ECMWF 2020)	European Centre for Medium-Range Weather Forecast (ECMWF)	1979-current
MERRA-2 Modern-Era Retrospective Analysis for research and applications (NASA, 2017)	US National Aeronautics and Space Administration (NASA)	1980- current
PRISM (PCIC 2014)	Pacific Climate Impact Consortium (PCIC)	1950-2007

Source: Compiled in text.

ERA-5 and MERRA-2 are global datasets that provide sub-daily values for multiple meteorological parameters. PRISM is a climate-elevation regression model, used to generate a reanalysis dataset that provides precipitation and maximum and minimum temperature averages on a monthly timestep for the Pacific Region of Canada and the northwestern USA.

2.3 Summary of Available Data

This section presents a summary of the Project Area and regional meteorological datasets.

Meteorological parameters were summarized for the three years of Project data using monthly averages of daily minimum, mean and maximum air temperatures. Monthly average sums of the minimum, mean and maximum total precipitation were calculated. Annual maximum snow water equivalent (SWE) was computed for the Project based on regional snow survey data, transposed to the Project Area.

Other parameters measured at the Tenas Deposit Station include: Wind speed and direction, solar radiation, relative humidity, and barometric/atmospheric pressure. Evaporation rates were calculated based on thes parameters. Measured and calculated parameters are summarized for the Project Area and the long-term regional records in the following sections.

2.3.1 Air Temperature

Project

Temperature is used to estimate snowmelt, evaporation, evapotranspiration, and other inputs such as pond freeze depths. Air temperatures recorded at the Tenas Deposit Station ranged from -31.7°C (January 15, 2020) to 34.5°C (June 27, 2021). Figure 2-6 presents the daily maximum,

average and minimum temperature at the Tenas Deposit Station. During the period of record, the coldest month was the month of December 2021 with a mean temperature of -14.0°C, and the hottest month was the month of July 2018 at 15.5°C. The summary of monthly maximum, average and minimum daily temperatures is presented in Table 2-4.

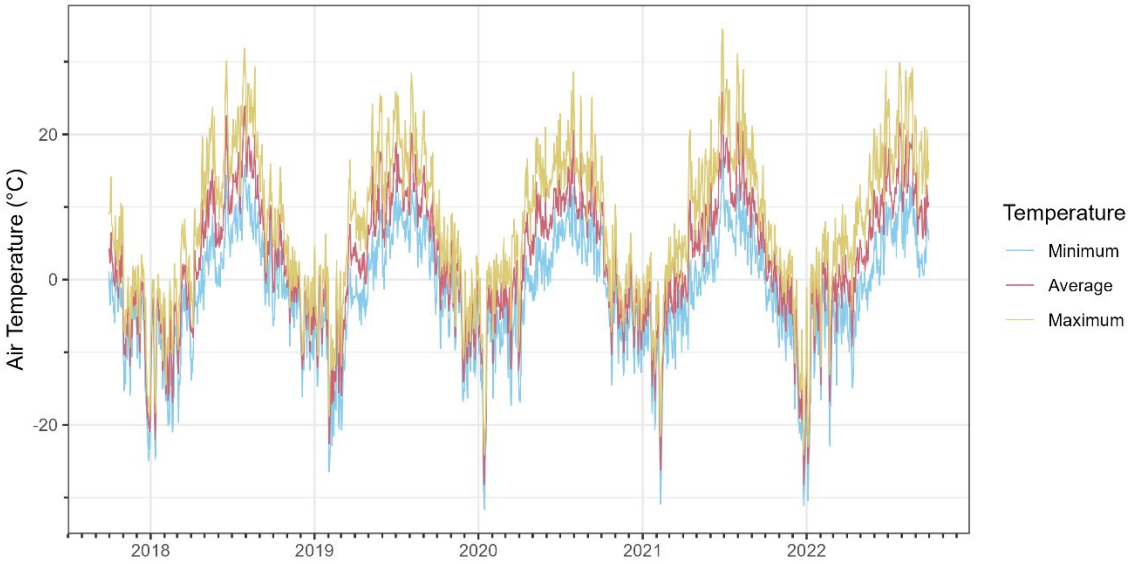

Figure 2-6: Tenas Deposit Meteorological Station Temperature Record

Regional

Temperature records for the Smithers Airport station were extended and patched using data from the Houston station. Figure 2-7 shows the annual distribution of regional temperatures, where the coldest and warmest months are typically January and July, respectively. Regional stations show similar temperature behaviour throughout the year except for Tsai Creek and Equity Silver. These two regional stations appear to show milder winters suggesting a temperature inversion for higher elevations. This suggests monthly correction factors are more appropriate to account for the potential of temperature inversions during the winter months.

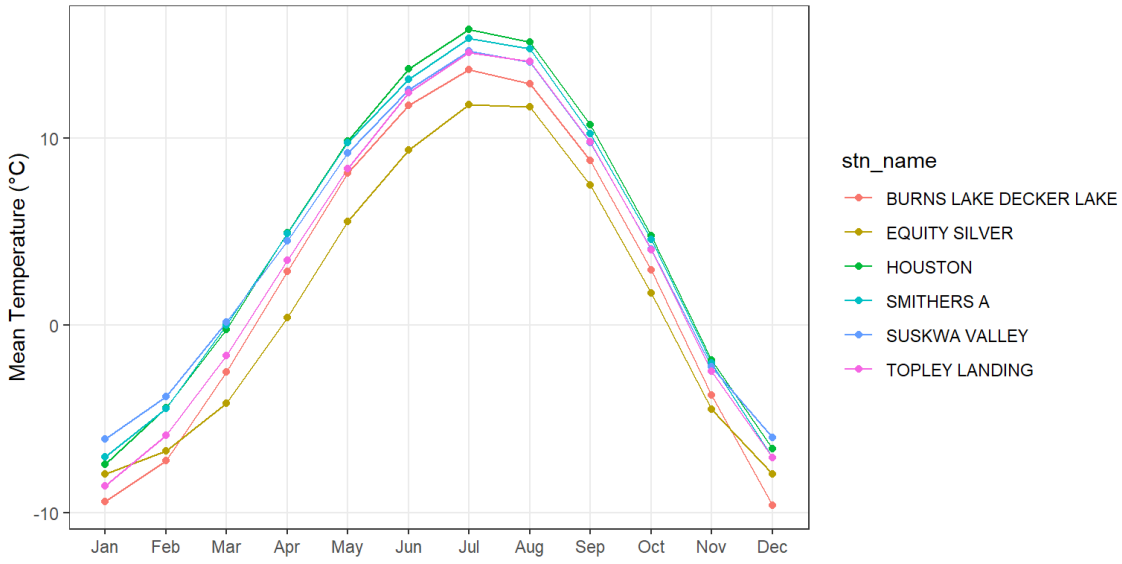

Figure 2-7: Monthly Average Temperatures at Regional Meteorological Stations

Source: \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html

Regionally, mean annual temperature decreases with increasing elevation. For a Project site elevation of 993 m (corresponding to the location of the Tenas Deposit Station), the mean annual temperature is approximately 2.5°C colder than temperatures recorded at the Smithers Airport Station (Figure 2-8).

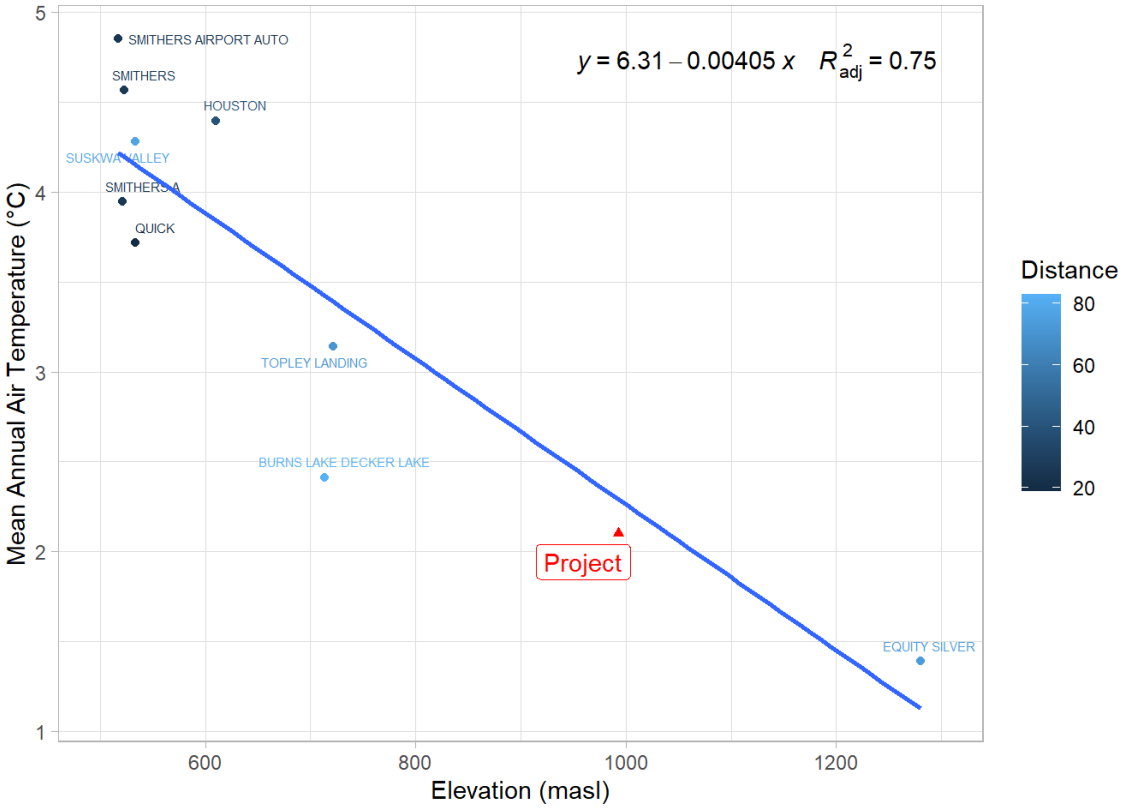

Figure 2-8: Regional Mean Annual Temperature – Elevation Trend

Source: \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html

2.3.2 Precipitation

Project

The Tenas Deposit Station recorded annual precipitation from 502 mm to 719 mm in 2018 – 2021. Figure 2-9 presents the recorded daily precipitation from October 2017 to September 2022. The largest single-day precipitation events occurred on 24 October 2017 for rainfall (73 mm) and on 7 February 2018 for snowfall (65 mm). The 24 October 2017 event corresponds to an exceptional runoff event that exceeded historical streamflow records for regional stations in the area (ERM 2019).

The recorded total precipitation at the Tenas Deposit Station (Figure 2-9) was divided into rainfall (mm) and snowfall (mm SWE) components if the Project air temperature record was less than 0 degrees Celsius. Using this estimation, snow ranged from 34% to 71% of total annual precipitation (see Table 2-8 for regional comparison). Monthly cumulative values of measured total precipitation and estimated rainfall and snowfall are summarized in Table 2-5.

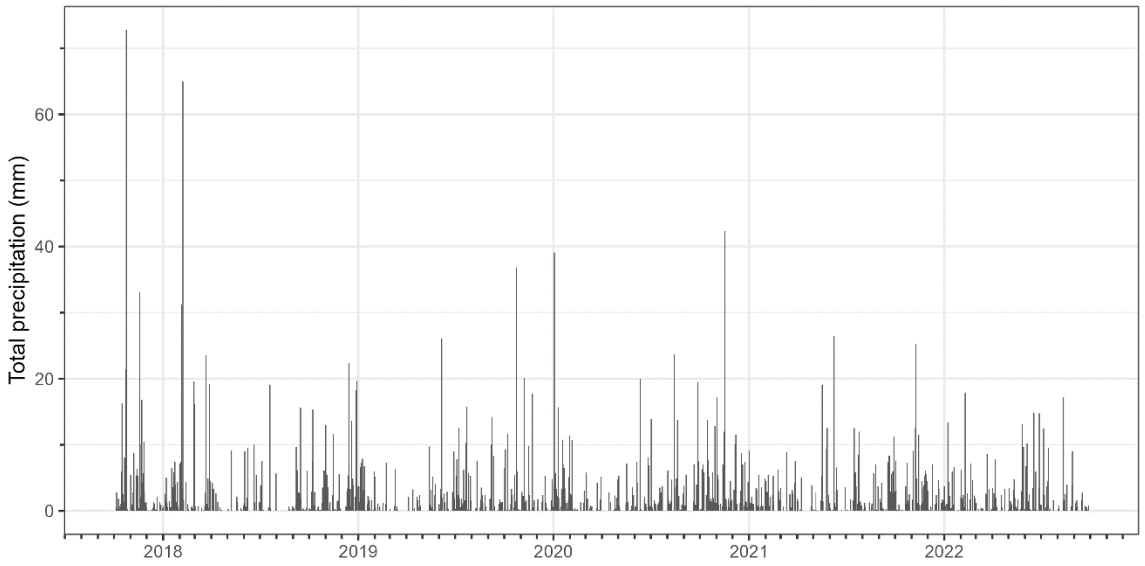

Figure 2-9: Tenas Deposit Meteorological Station Measured Total Precipitation for October 2017-2019

Source: compiled from R code \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html

Table 2-5: Tenas Deposit Meteorological Station Total Precipitation (measured), Rain (estimated), Snow (estimated)

Year	Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual Total
2017	Total Precipitation [mm]										147	134	10	--
	Rainfall [mm]										114	0	0	--
	Snowfall [mm SWE]										33	134	10	--

Regional

A regional precipitation analysis was carried out to identify trends and elevation correlations. The Smithers Airport Auto and Smithers A stations (10775001 and 1077500) were merged to generate a long-term record. Remaining gaps in this record were patched with Quick as well as ERA-5, using quantile mapping methods. The resulting patched Smithers A record provides 73 years of complete data.

Average yearly precipitation, rainfall and snowfall for regional stations are presented in Table 2-6 for their corresponding period of record. Regional stations present varying mean annual precipitation (MAP) in the range of 415 mm to 760 mm with precipitation occurring mainly as rainfall except for Equity Silver where almost half of the precipitation falls as snow due to its higher elevation.

Table 2-6: Regional Stations Annual Precipitation, Rain, Snow and Corresponding Proportions

Station	Mean Annual Precipitation [mm]	Mean Annual Rainfall [mm]	Mean Annual Rainfall [%]	Mean Annual Snowfall [SWE mm]	Mean Annual Snowfall [%]
SMITHERS A (patched)	511	344	67%	166	33%
QUICK	469	308	66%	161	34%
HOUSTON	425	293	69%	132	31%
TOPLEY LANDING	539	310	58%	229	42%
EQUITY SILVER	661	348	53%	314	47%
SUSKWA VALLEY	756	552	73%	204	27%
BURNS LAKE DECKER LAKE	415	249	60%	166	40%

Notes:
1. Rainfall and snowfall proportions as percentages of the mean annual precipitation.
2. Smithers A patched with Smithers Airport Auto, Quick and ERA-5.
3. Mean annual values calculated based only on years with snow and rain measurements

Source: compiled in text from R code \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html and Canadian Climate Normals https://climate.weather.gc.ca/climate_normals/index_e.html

Figure 2-10 illustrates the regional correlation between MAP and elevation. A negative value for the determination coefficient (R^2 presented in Figure 2-10) indicates the correlation between elevation and MAP using only the regional meteorological datasets is poor.

The relationship between MAP and elevation is likely less significant at this location due to the more dominant effects of topography and the Pacific Ocean as a moisture source. The west-east gradient and proximity to mountain range with rain shadow effects are the most important factors affecting precipitation in this area. Orographic gradients were further evaluated using Reanalysis datasets and are discussed in Section 4.1.2.

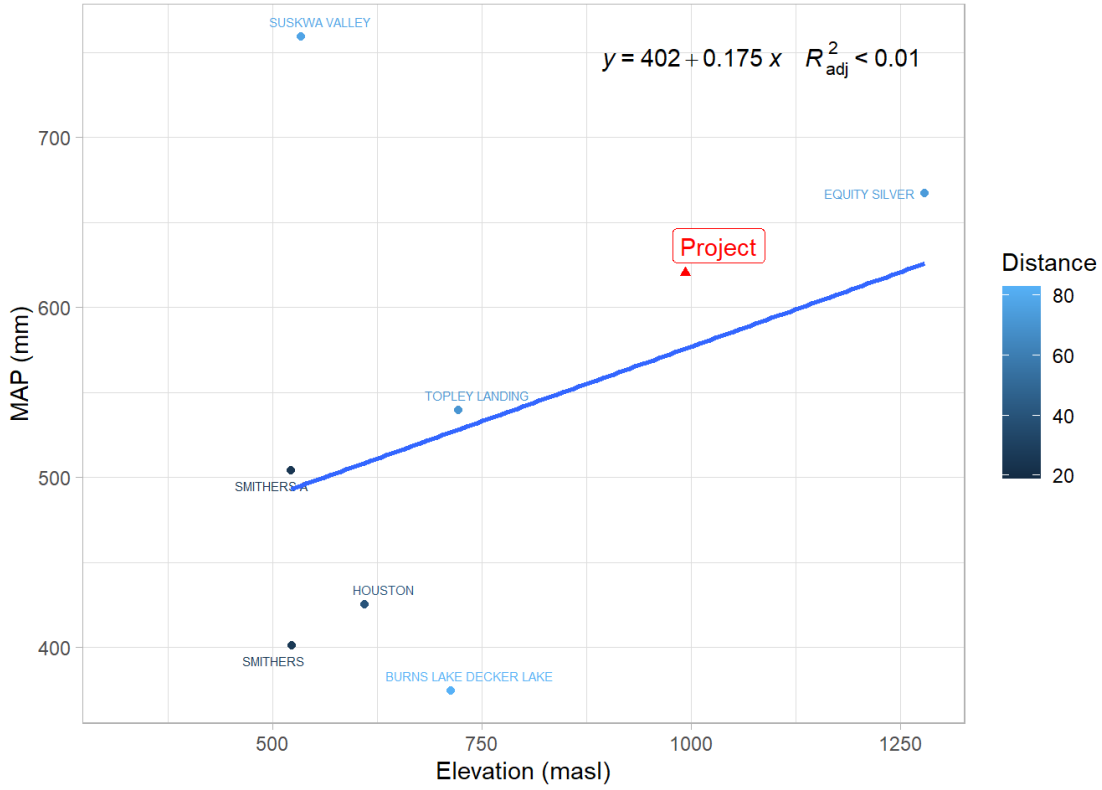

Figure 2-10: Regional Mean Annual Precipitation – Elevation Trend

Note: Quick station data not included due to differing timelines
Source: compiled in text from R code \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html

Monthly precipitation was also reviewed and compared to site data over the concurrent period of record. Monthly precipitation data for the regional stations is presented in Table 2-7.

2.3.3 Snow Depth

Project

Table 2-8 presents the daily mean snow depth data recorded at the Tenas Deposit Station. Snowpack at the Project does not have a large potential of being redistributed by wind as the general surrounding area is heavily forested and recorded wind speeds are low (see Section 2.3.4). Snow depth measurements recorded at the Tenas Deposit Station are believed to be representative of the Project (ERM 2019). Snow depths are measured continuously at the Project while snowpack snow water equivalent measurements are not available.

Table 2-8: Snow Depth Summary at Tenas Deposit Station for October 2017 to 2022

Year	Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
2017	Maximum Snow Depth [cm]										16	60	51

Regional

The Tenas Deposit Station records total precipitation and snow depth but does not measure the snow water equivalent. The automated regional snow pillow station operated by environment Canada at Tsai Creek measures precipitation, temperature, snow depth and hourly snow water equivalent. The snow depth record at Tsai Creek is much higher than the snow depth record at the Tenas Deposit Station although the accumulation pattern is similar. However, melt timing occurs later at Tsai Creek due to the elevation difference between the two stations as well as

other physiographic characteristics such as aspect. At Tsai Creek, snowmelt typically begins in April, peaks in May and then is finished by early June.

Hudson Bay manual survey station also offers records near the Project. Figure 2-11 illustrates snow depth records at these regional stations compared to the project records, and Table 2-9 presents monthly average snow depth at Tsai Creek together with monthly survey results carried out at Hudson Bay.

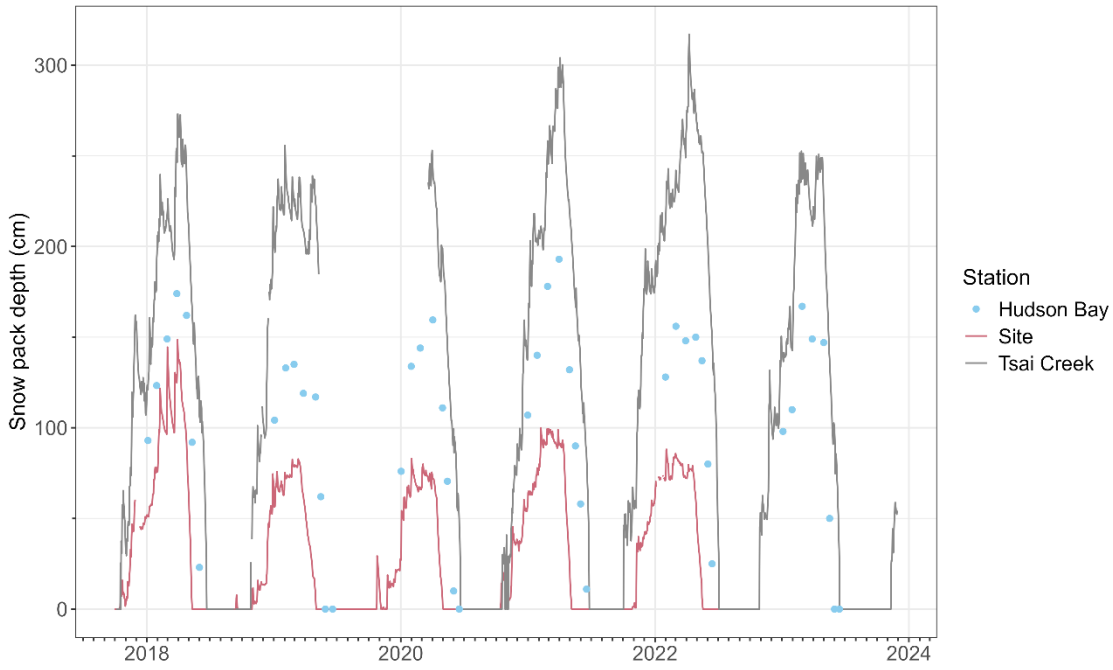

Figure 2-11: Snow Depth Records at Tsai Creek, Hudson Bay and Tenas Deposit

2.3.4 Wind

Project

Wind speeds at the Project are generally low (less than 2 m/s) and are predominantly from the southwest (i.e., travelling down the Tenas Creek watershed). Figure 2-12 illustrates the wind rose representing wind speed data for the hydrologic year from October 2017 to September 2022. Table 2-10 presents the monthly average wind speed for each year of record from the Project station. The maximum hourly mean wind speed recorded at the Tenas Deposit Station between October 2017 to September 2022 was 6.7 m/s and the maximum wind gust speed was 15.9 m/s.

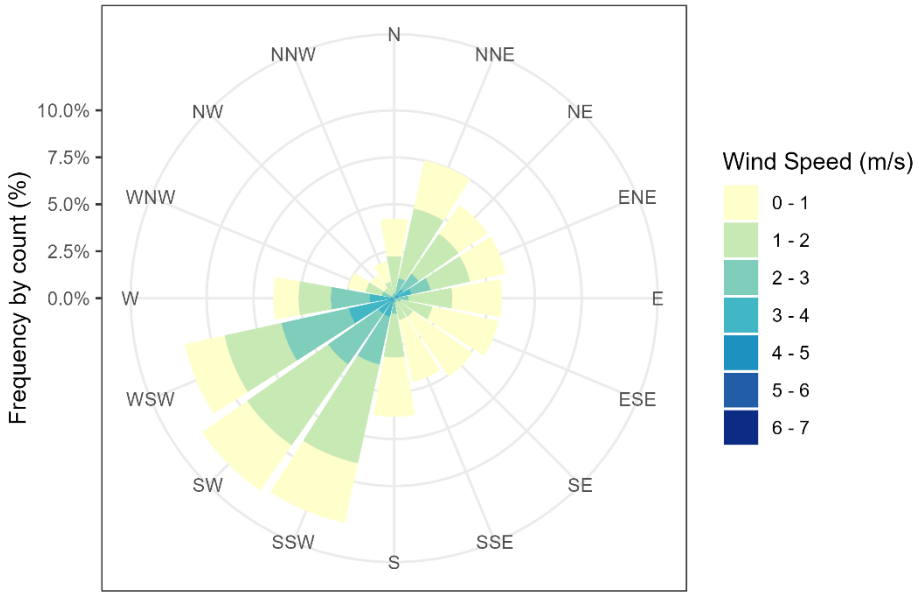

Figure 2-12: Wind Rose at Project for 2017-2022

Source: compiled from R code \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html

Table 2-10: Project Monthly Average Wind Speed Summary [m/s]

Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
2017										1.2	1.1	0.9
2018	0.7	1.2	1.5	2.0	2.5	2.9	3.3	2.3	1.4	1.1	0.9	1.1
2019	1.0	1.4	1.3	1.6	1.8	1.7	1.4	1.5	1.3	1.1	1.2	0.7
2020	1.2	1.5	1.8	1.7	1.9	1.8	1.7	1.6	1.1	1.2	1.2	1.0

Regional

Winds at the Smithers Airport station were found to be predominantly from the southeast and slightly higher than the Project Area. Wind speeds are typically used to evaluate evaporation and wave run-up and setup for freeboard estimates. Given the short period of record overlap, it was determined that higher wind speed measured at the Smithers Airport station is conservative and appropriate for application to the Project.

Figure 2-13 illustrates the wind roses based on wind speeds recorded from October 2017 to November 2023 at Smithers Airport station.

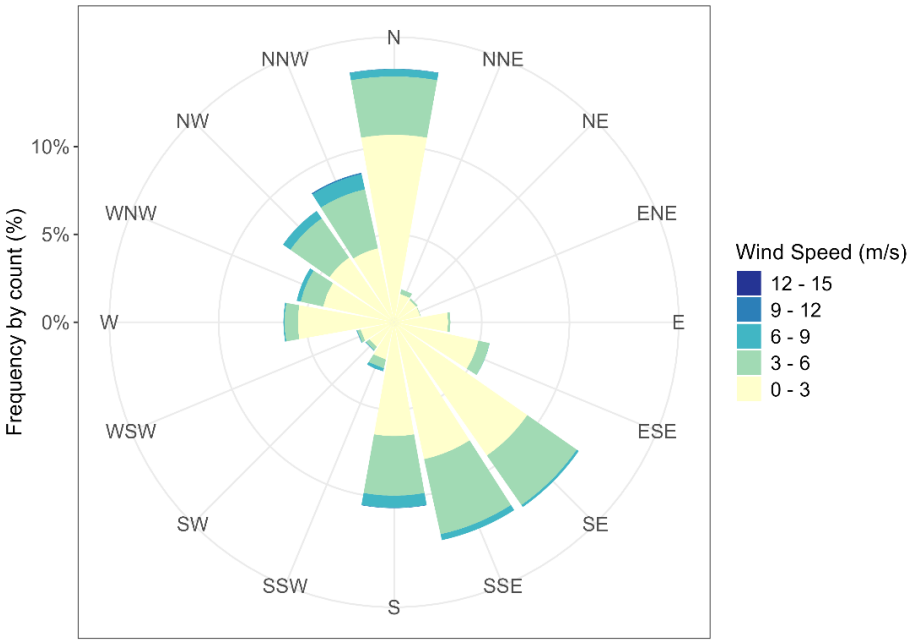

Figure 2-13: Wind Rose for Smithers A – October 2017 to November 2023

Source: compiled in text from R code \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html

Smithers A values have been adapted to the Project for design purposes but should be replaced with Project-specific data when it becomes available. Wind speeds are typically not transposable across large distances and due to physiographic characteristics unique to each location. Table 2-11 summarizes the monthly average wind speeds and Table 2-12 presents the frequency analysis for sustained wind speeds adopted for the Project.

Table 2-11: Average Monthly Wind Speed [m/s] at Smithers A Regional Station

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual

2.3.5 Solar Radiation

Project

The amount and intensity of solar radiation is a function of elevation, latitude, catchment orientation (slope and aspect) and shadows cast by topographic features and the atmosphere (i.e., cloud cover). Solar radiation at the Tenas Deposit Station is measured in power density units of W/m^2. Many periods of erroneous data were removed from the dataset due to snow accumulation on top of the sensor. Figure 2-14 illustrates daily solar radiation measured at the Tenas Deposit Station from October 2017 to September 2022.

Average daily solar radiation ranged from 1.5 W/m^2 to 376 W/m^2. As illustrated, incoming solar radiation has both seasonal and annual cycles. Diurnal variation in the sub-daily record (not shown) demonstrate typically higher values at midday and during summer while lower values typically occur between late evening to morning, and in winter. Table 2-13 presents the average monthly solar radiation at the Tenas Deposit Station.

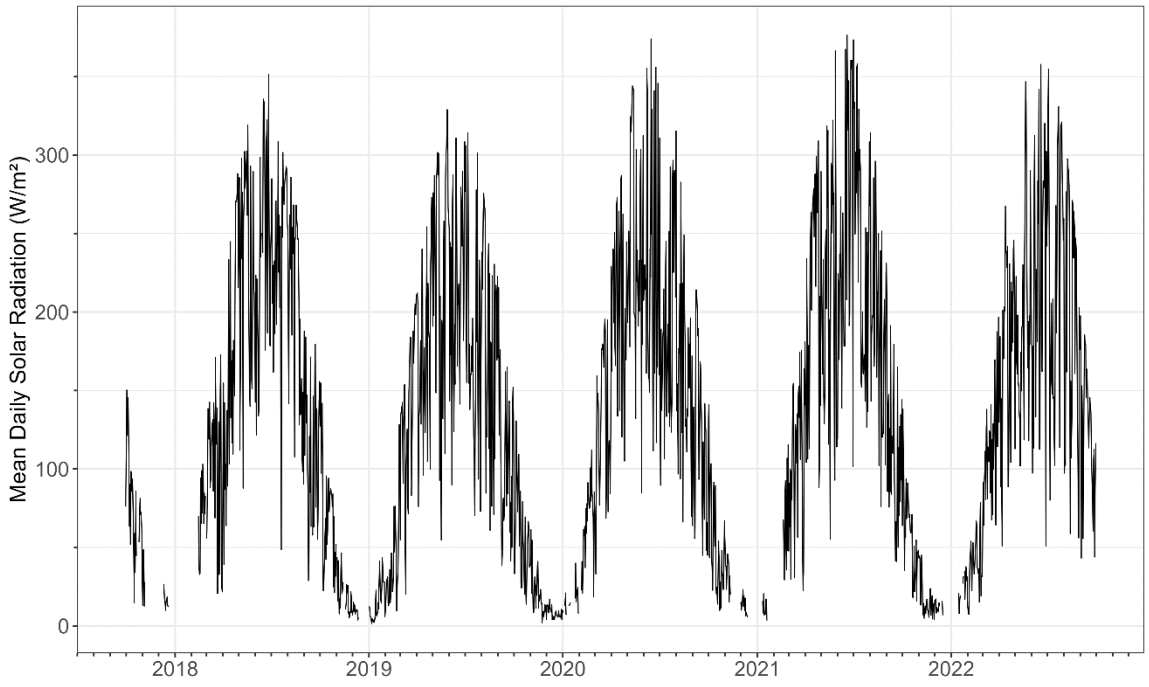

Figure 2-14: Average Daily Solar Radiation at the Tenas Deposit Station for October 2017 to 2019

Source: compiled from R code \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html

Table 2-13: Average Monthly Solar Radiation at the Tenas Deposit Station for October 2017 to 2022 [W/m^2]

*Light grey denotes no measurements.

Source: compiled in text from R code \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html

Regional

The Smithers Airport Station does not record solar radiation. The Canadian Weather Energy and Engineering Dataset (CWEEDS) dataset is available for the location of Smithers Airport and was compared to incoming solar radiation recorded at the Tenas Deposit Station. Table 2-14 presents the average monthly solar radiation at the Smithers Airport station from the CWEEDS dataset.

Table 2-14: Average Monthly Solar Radiation [W/m^2] at Smithers Airport Location

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
Average	67	133	249	366	465	485	425	327	232	147	77	48	196

Source: compiled in text from R code \\srk.ad\dfs\na\van\Projects\01_SITES\Telkwa Coal\1CT027.003_2020 EA Water Management\200_Meteorology_Update\R work\Telkwa_EA_Evaporation_1CT027.003_rev01.Rmd

Based on available data, incoming solar radiation at the Project was found to be lower than the solar radiation from the CWEEDS dataset for the Smithers Airport location, understood to be due to the former being located in the north face of a mountain while the latter is located in an open, flat location and receives greater insolation.

2.3.6 Relative Humidity

Relative humidity refers to the ratio of the amount of moisture in the air to the relative maximum potential amount that air could hold at a given temperature and atmospheric pressure. As relative humidity approaches 100%, the likelihood of precipitation increases. On a monthly basis, the average relative humidity was typically greatest from November to January, remaining consistently above 85%, and was the lowest overall during the months of July and August (Figure 2-16). The monthly maximum, average and minimum daily relative humidity values are summarized in Table 2-15.

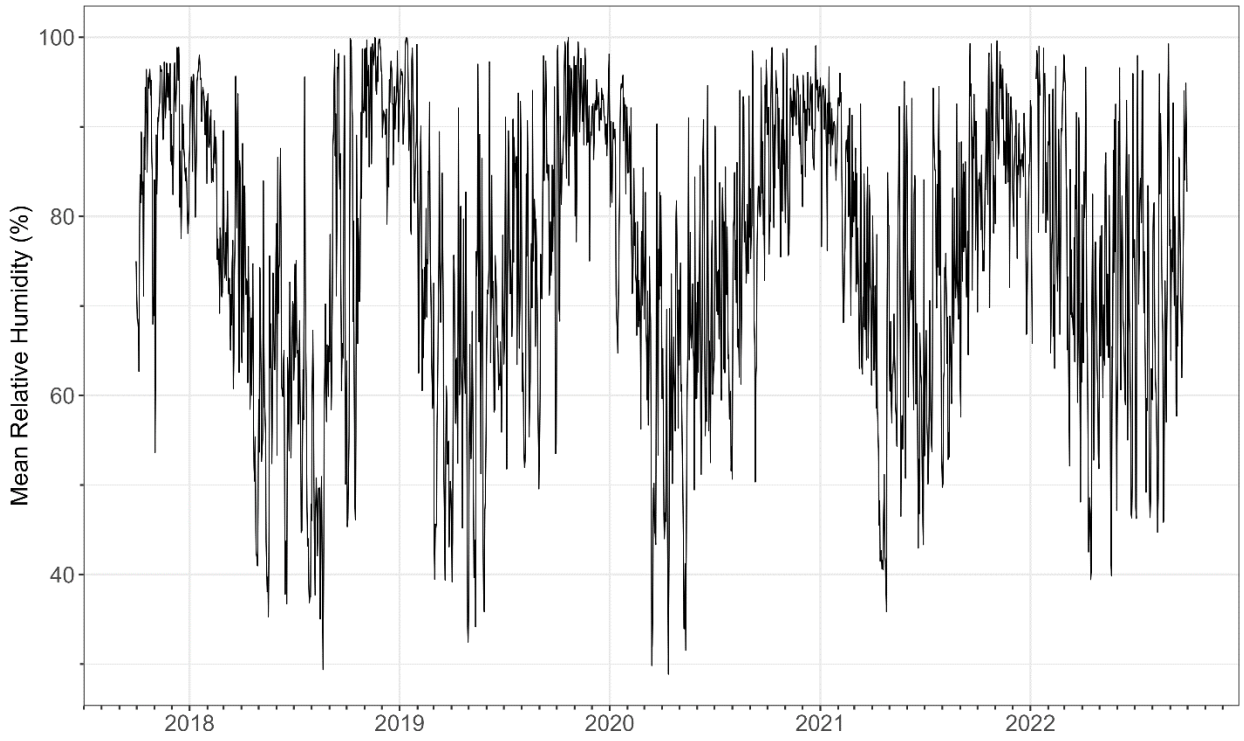

Figure 2-15: Average Daily Relative Humidity at the Tenas Deposit Station for October 2017 to September 2022

Regional

Hourly relative humidity recorded at the Smithers Airport station was evaluated for the period of record (1953-2023) and the monthly average values are presented in Table 2-16. Patterns in relative humidity were similar to what was observed at the Tenas Deposit Station.

Table 2-16: Average Monthly Relative Humidity [%] at Smithers A Location

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
Average (%)	83.3	79.3	71.6	63.8	62.2	66.4	69.8	73.4	80.2	82.2	85.8	85.0	75.2

Source: compiled in text from R code \\srk.ad\dfs\na\van\Projects\01_SITES\Telkwa Coal\1CT027.003_2020 EA Water Management\200_Meteorology_Update\R work\Telkwa_EA_Evaporation_1CT027.003_rev01.Rmd

Monthly relative humidity values were compared between October 2017 and September 2022 and are shown in Figure 2-16, where the red line represents the identity function. Based on these records, the Smithers Airport station relative humidity is generally lower than at the Tenas Deposit Station.

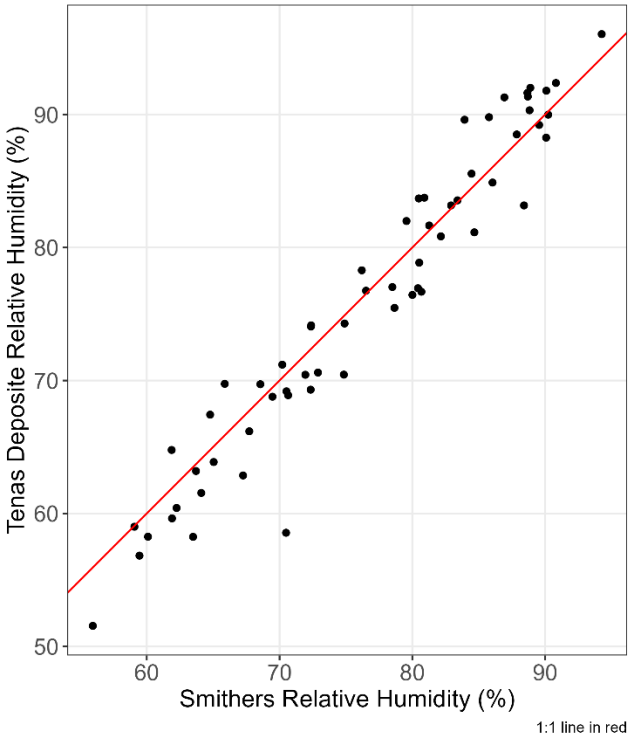

Figure 2-16: Monthly Average Relative Humidity at Smithers Airport Station and Tenas Deposit Station for October 2017 to September 2022

2.3.7 Evaporation

Project

Open water evaporation is an important component of the water balance for the Project area. Since the initial EAC application (Aug 2022), new pan evaporation data from site has become available from 2019 and 2022 readings. Daily records are illustrated in Figure 2-17. The monthly total evaporation values are summarized in Table 2-17 showing only complete months of data (August 2019 and June-September 2022).

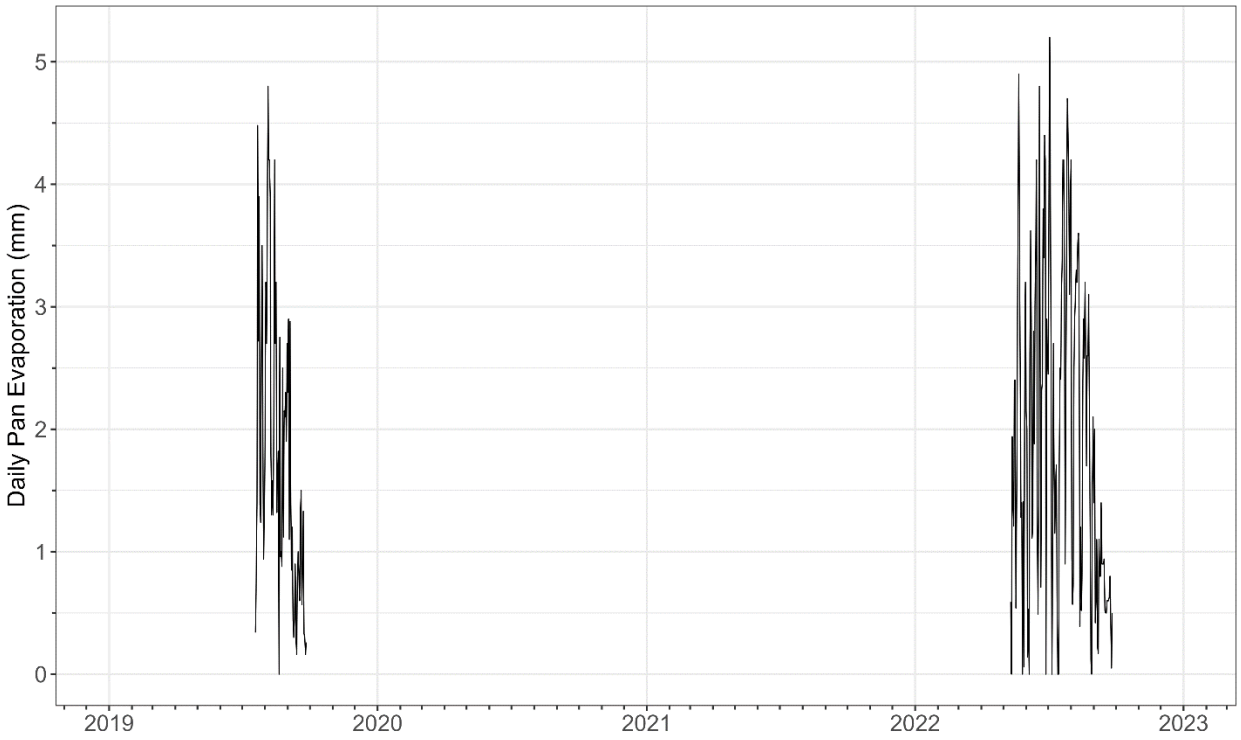

Figure 2-17: Daily Pan Evaporation at the Tenas Deposit Station for July 2019 to September 2022

Regional

Two approaches were used in order to evaluate open water evaporation: (1) Penman (Penman, 1948) and (2) Morton CRWE (Morton, 1983) approaches. The Penman and Morton CRWE approaches were applied to three datasets to estimate mean daily potential evaporation and then subsequently compared to the Topley Landing pan evaporation measurements (adjusted to represent lake evaporation). The three datasets are: (1) patched regional data (Smithers Airport Station), (2) patched Project data (Tenas Deposit Station) and (3) derived Project data based on reanalysis and regional datasets. Monthly average lake evaporation results are presented in Figure 2-18.

The Penman formula is a semi-empirical equation that incorporates energy budget and mass transfer approaches to estimate daily potential evapotranspiration or open water evaporation. Open water evaporation E_0 (in mm/day) is calculated according to the formula:

$$E_o = \frac{\left(\frac{\Delta}{\gamma} H + E_a\right)}{\frac{\Delta}{\gamma} + 1}$$

Where $\frac{\Delta}{\gamma}$ is an empirical parameter dependent on temperature, H is calculated based on incoming solar radiation, outgoing radiation, albedo of the open water surface and the proportion of cloudiness.

E_a is calculated semi-empirically as well using windspeed, and vapour pressure.

The Morton CRWE formula generates an estimate of monthly potential evaporation using the input parameters in Table 2-18.

Table 2-18: Morton CRWE Evaporation Formulation Input Parameters

Parameter	Description	Value
T_{max}, T_{min}	Timeseries of daily maximum and minimum project temperatures	See Section 2.3.1, 4.2.2
RH_{max}, RH_{min}	Timeseries of daily maximum and minimum project relative humidity	See Section 2.3.6, 4.1
T_{dew}	Timeseries of daily project dew point temperature.	Computed with the Magnus Formula (Magnus, 1844)
Rs	Timeseries of daily project solar irradiance	See Section 2.3.5, 4.2.5
epsilon	Surface emissivity (Morton, 1986)	0.92

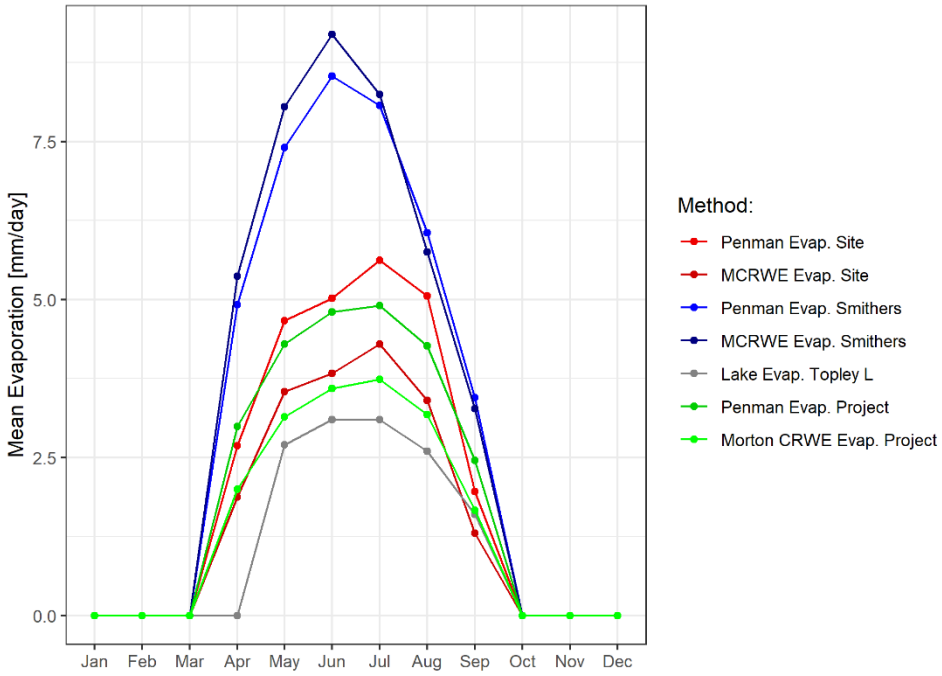

Figure 2-18: Estimated Monthly Average Lake Evaporation

The only regional station with evaporation measurements is Topley Landing, located 71 km northeast of the Project at an elevation of 722 masl. Mean annual lake evaporation at Topley Landing was 401 mm based on the 1981-2010 Canadian Climate Normals published by Environment Canada. Note that relative humidity and solar radiation are not measured at Topley Landing so the methods listed above could not be directly compared for Topley Landing.

3 Baseline Hydrology

3.1 Section Overview

The baseline characterization incorporates historical flow records from selected long-term Water Survey of Canada (WSC) stations as well as available data from local Project hydrometric stations.

Local data has been collected as part of the Tenas Project baseline monitoring program. Information from September 2017 to September 2018 is synthesized in the Tenas Project 2017 to 2018 Baseline Report (ERM 2019) with more recent information provided by ERM in the form of field reports. New hydrologic data has also been collected at Tenas-Hydro, and Four-Hydro stations between 2021 and 2022. Additional data collected by AGRA Earth and Environmental Ltd in 1997-1998 is presented in Attachment C.

Hydrometric records generated for the Project Area spanning 2017 to 2022 are shown in Section 3.2 for the open water period. Regional data for each Water Survey of Canada station are discussed in Section 3.2 and summarized in Section 3.3.

3.2 Available Hydrometric Data

3.2.1 Project Data

Catchment Delineations

Catchment areas were defined by ERM (ERM 2019) and verified by SRK. Project Area hydrometric stations as well as regional Water Survey of Canada stations are shown in Figure 3-1.

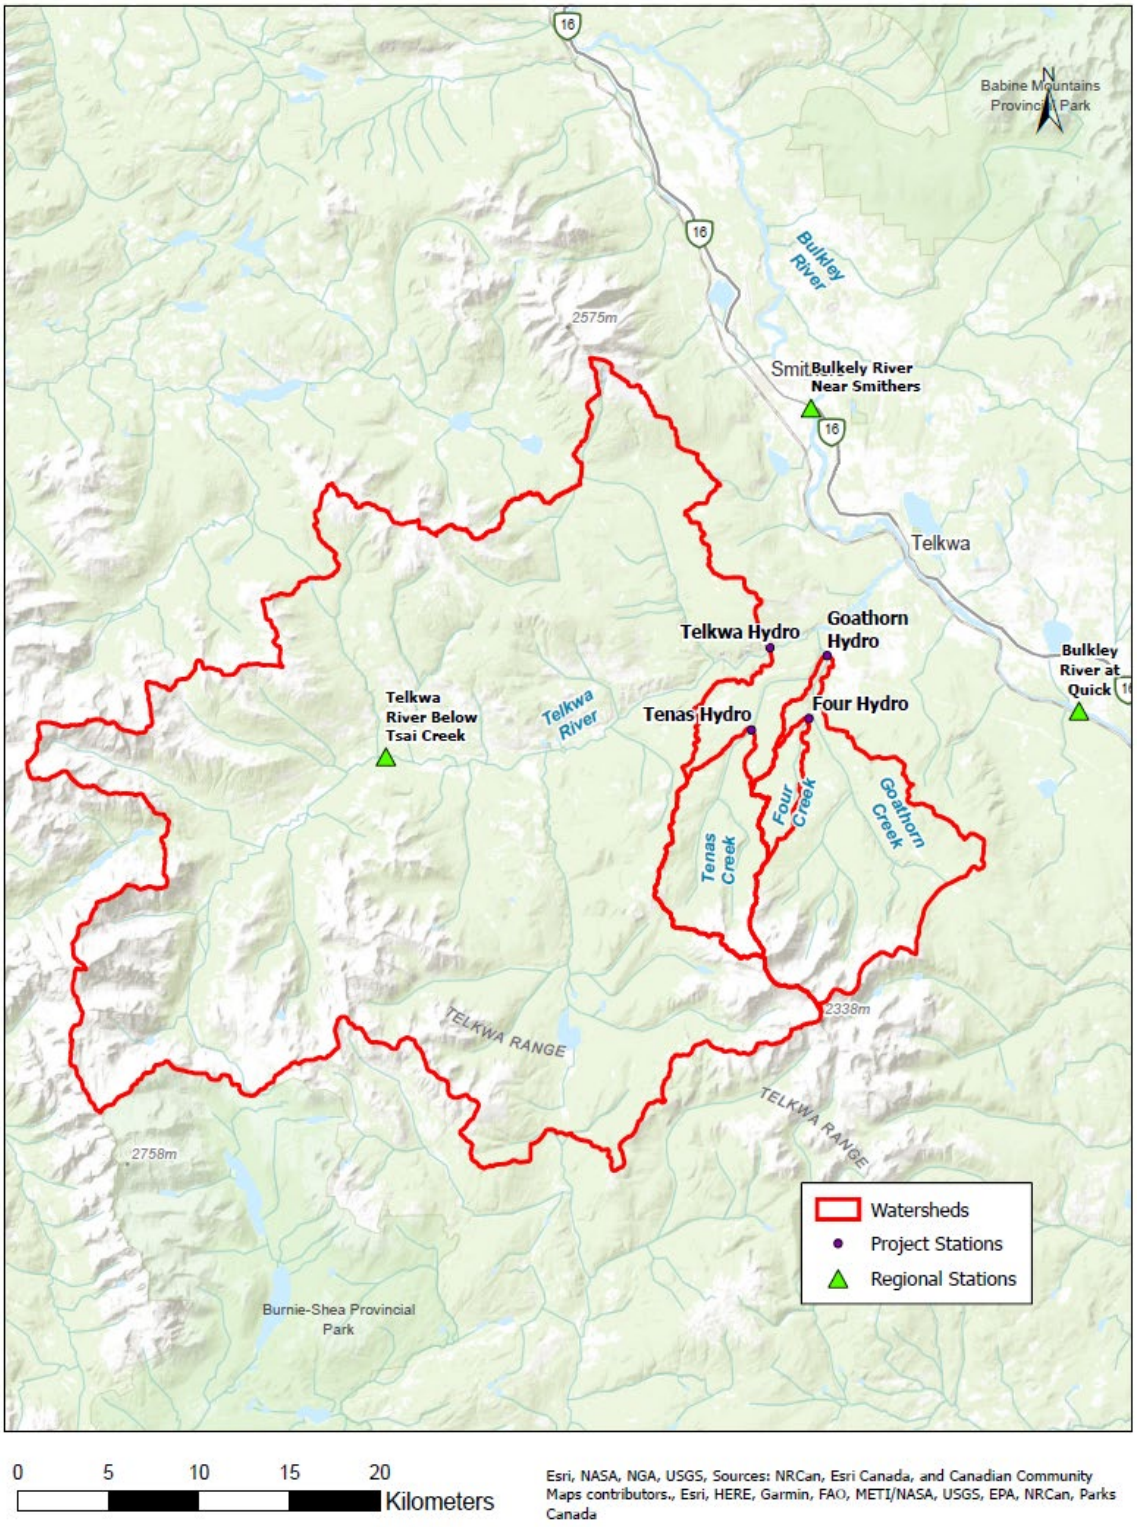

Figure 3-1: Map of Project Area With Project Hydrometric Station Catchments Delineated

Hydrometric Data

Historical hydrometric data was collected in 1997-1998 by AGRA Earth and Environmental Ltd for development of the Project Area by Luscar Ltd. Hydrometric spot measurements were collected at Four Creek and Tenas Creek and converted to continuous discharge for a subset of each open-water season. Four Creek data from this period was assessed in more detail than Tenas Creek records due to the short duration of data collected in 2020 by ERM.

Table 3-1 summarizes relevant information for each Project hydrometric station.

Recent rating curves and continuous discharge were developed for each hydrometric station by ERM (Figure 3-2). Additional details on the instrumentation and rating curve development is summarized in the 2017-2018 Baseline Report (ERM 2019). The Tenas-Hydro station was moved approximately 200 m upstream in 2018. Additional monitoring, rating curve development and analysis for 2019 hydrometric data was completed by ERM.

The Four-Hydro station was installed in April 2020. Monitoring of other local hydrometric stations in 2020 was not completed. Additional streamflow data were collected in Four Creek and Tenas Creek in 2021 and 2022.

Table 3-1: Summary of Project Area Hydrometric Stations Location and Measurement Information

3.2.2 Regional Data

Water Survey of Canada (WSC) is the national authority responsible for the collection, interpretation and dissemination of standardized water resource data in Canada. Stations within the same BC hydrological zone were evaluated and additional selection criteria were subsequently applied.

Figure 3-1 illustrates the four regional WSC stations selected based on proximity to the Project hydrometric stations as well as for having similar flow regimes. These stations have more than 10 years of data and catchment areas ranging between 125 km^2 to 8,940 km^2. Table 3-2 summaries the metadata for these stations and the length of published historical record.

Table 3-2: Summary of Regional Hydrometric Stations

Station ID	Station Name	Longitude [°]	Latitude [°]	Area [km^2]	First Year	Last Year
08EE008	Goathorn Creek near Telkwa	54.65	-127.12	125	1960	2024[1]
08EE020	Telkwa River below Tsai Creek	54.61	-127.50	367	1975	2024
08EE004	Bulkley River at Quick	54.62	-126.90	7,340	1930	2020
08EE005	Bulkley River near Smithers	54.77	-127.13	8,940	1945	2023

Source: compiled in text from R code \\srk.ad\dfs\na\van\Projects\01_SITES\Telkwa Coal\1CT027.002 2017-18 permitting Support (Phase 2)\0200_SurfaceWater\Hydrology\R files\Flows_update_rev02.Rmd

Notes:
1. Goathorn Creek near Telkwa (08EE008) was decommissioned in January 2018 and re-installed in October 2019.

Discharge from all four Water Survey of Canada regional stations (Table 3-2) followed a nival regime with an initial increase in discharge observed in April followed by annual maximum in response to snowmelt typically during May. Discharge responded to rainfall events throughout the summer and a recession to annual low flows was observable in the late fall and winter. The time series of each regional hydrometric station are shown in Figure 3-3, Figure 3-4 , Figure 3-5, Figure 3-6.

3.3 Summary of Available Data

3.3.1 Project Hydrometric Monitoring Data

Discharge

Historical Four Creek discharge data for 1997-1998 will not be presented in this section but is summarized in Attachment C. Continuous discharge was generated from water level measurements and rating curves developed for each Project Area hydrometric station for the open water period. Average monthly discharge are presented for each station in Table 3-3 and unit discharge values are presented in Table 3-4 by dividing monthly average flow by the associated catchment area (Table 3-1).

Table 3-3: Average Monthly Discharge for the Open-Water Period (m^3/s)

Low Flows

Low flows are critically important parameters due to their low dilution capacity as well as the implications for biological organisms. Low flow statistics are based on available records to estimate the lowest flow within a watercourse over some period of time. Low flow statistics are expressed as an averaging period (e.g., 7 day average) over a recurrence interval where 10 years is common for hydrologically-based flows (7Q10). A low flow calculation requires several years of record as a distribution model (i.e, Log Pearson Type III) is applied to the collected lowest flow event from each year of record. The short length of the Project Area hydrometric records does not allow for a 7Q10 calculation. Low flows were therefore conservatively estimated as the minimum daily average flow for each month for each station (Table 3-5).

Table 3-5: Minimum Instantaneous Discharge (m^3/s)

Station Name	Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual

3.3.2 Regional Hydrometric Records

Discharge

Discharge data from Water Survey of Canada compiled for each station was summarized as average monthly and annual discharge for the four regional hydrometric stations (Table 3-6).

Table 3-6: Average Monthly and Mean Annual Discharge (m^3/s)

Station Name	Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Ann.

Unit Discharge

The monthly average discharge for each regional station was converted to unit discharge, which normalizes discharge per unit area of the catchment (Table 3-7).

Table 3-7: Average Monthly and Annual Unit Discharge (L/s/km^2)

Station Name	Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Ann.

4 Derived Project Parameters

4.1 Derived Meteorological Parameters

Due the the relatively short record of Tenas Deposit Station data, meteorological parameters for the Project are derived by adjusting the patched long-term datasets at Smithers Airport to the site, based on spatial and orographic gradients. Adjustment factors are derived based on trends in regional stations, or when these are not adequate, reanalysis datasets, as described in the following sections.

4.1.1 Air Temperature

Historical Smithers Airport monthly temperatures were compared to the reanalysis datasets for the same location. Of the reanalysis datasets investigated, the PRISM model was determined to provide the best fit for precipitation as described in Section 4.1.2. Figure 4-1 illustrates the monthly temperature regression between measured and modelled PRISM temperatures at the Smithers Airport Station. Given the good correlation, PRISM data for the Project at the Tenas Deposit Station was obtained and monthly correction factors relative to the Smithers Airport station were developed to account for orographic gradients and temperature inversion effects (Table 4-1).

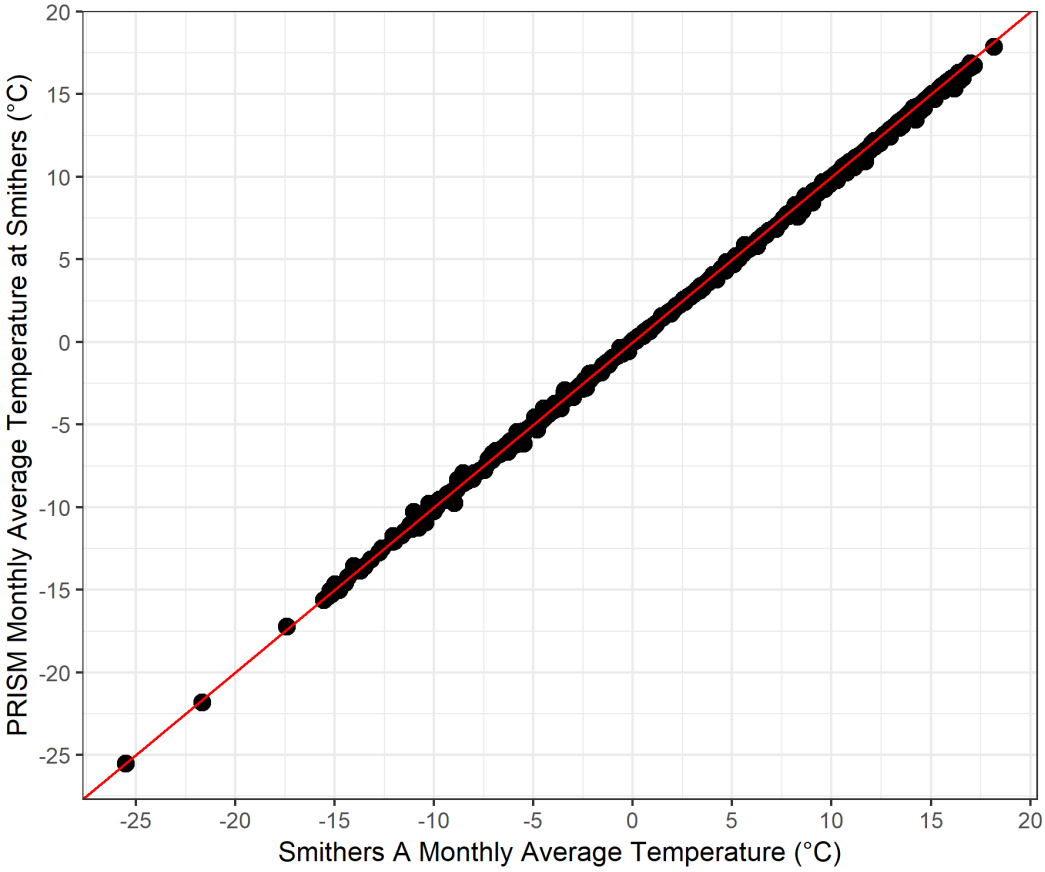

Figure 4-1: Smithers Airport vs PRISM Reanalysis

Source: compiled in text from R code \\srk.ad\dfs\na\van\Projects\01_SITES\Telkwa Coal\1CT027.003_2020 EA Water Management\200_Meteorology_Update\Rwork\Telkwa_EA_Temperature_1CT027.003_rev01.Rmd

Correction Factors and Expected Project Air Temperature

The correction factors presented in Table 4-1 were applied to the patched Smithers Airport Station temperature record to create a Project-adjusted long-term temperature record for design and modelling.

Table 4-1: Temperature Correction Factors

Month	Minimum Temperature			Average Temperature			Maximum Temperature		
	Smithers Airport (°C)	PRISM at Project (°C)	Absolute Temp. Ratio	Smithers Airport (°C)	PRISM at Project (°C)	Absolute Temp. Ratio	Smithers Airport (°C)	PRISM at Project (°C)	Absolute Temp. Ratio
January	-13.6	-13.5	1.000	-9.5	-9.9	0.998	-5.5	-6.3	0.997

Source: compiled in text from R code \\srk.ad\dfs\na\van\Projects\01_SITES\Telkwa Coal\1CT027.003_2020 EA Water Management\200_Meteorology_Update\R work\Telkwa_EA_Temperature_1CT027.003_rev01.Rmd

4.1.2 Precipitation

Figure 4-3 illustrates the monthly precipitation correlation between the 60 months of measured Project precipitation and patched precipitation records at Smithers for the overlapping period from October 2017 to September 2022. The total measured precipitation at the Tenas Deposit Station was approximately 34% greater than that at Smithers A over this period. The monthly precipitation difference ranged between -15 mm to +91 mm for Project data over the 60 months and suggests monthly correction factors are more appropriate to account for seasonality.

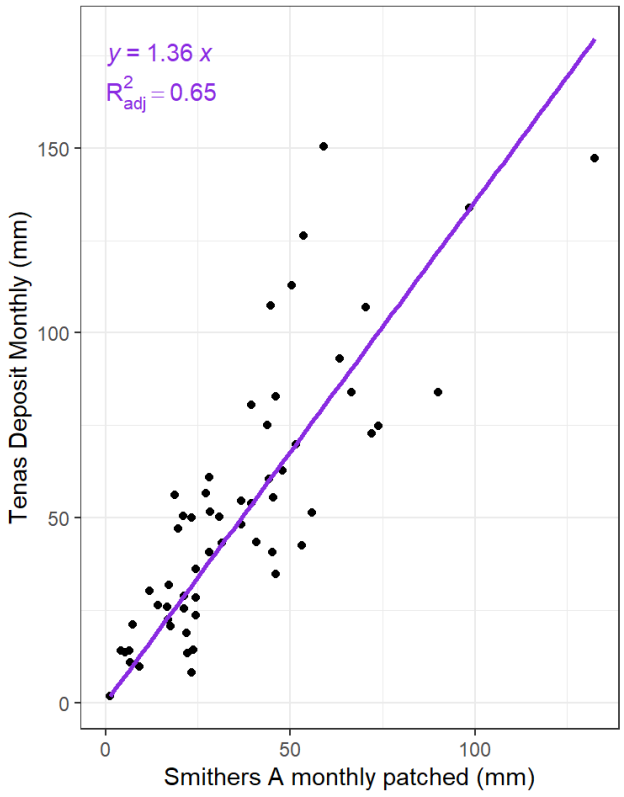

Figure 4-3: Comparison between Observed Total Precipitation at Tenas Deposit Station and Smithers A

Source: \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html

Typically, precipitation depths are expected to be greater at higher elevations. However, as previously demonstrated in Figure 2-10, there is a poor regional correlation between mean annual precipitation and elevation at the regional stations. Therefore, reanalysis datasets were evaluated against the patched Smithers A record to develop transposition factors to adjust the longer-term dataset to site (Table 4-3).

Table 4-3: Smithers A and Reanalysis Mean Monthly and Annual Precipitation Comparison [mm]

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Total
Smithers A (patched)	51	28	22	22	35	46	45	41	51	62	54	50	508
ERA 5	62	41	45	45	59	79	70	65	69	86	79	59	760
Merra 2	92	60	76	60	72	101	97	94	94	117	105	92	1059
PRISM	48	23	24	24	34	55	46	46	49	66	54	49	517

Source: compiled in text from R code \\srk.ad\dfs\na\van\Projects\01_SITES\Telkwa Coal\1CT027.003_2020 EA Water Management\200_Meteorology_Update\R work\Telkwa_EA_Precipitation_1CT027.003_rev01.Rmd

The PRISM reanalysis data was found to best represent the spatial precipitation distribution across elevations. The PRISM mean annual precipitation for the region surrounding the Project, shown in Figure 4-4, demonstrates the spatial and orographic variability of precipitation in the region.

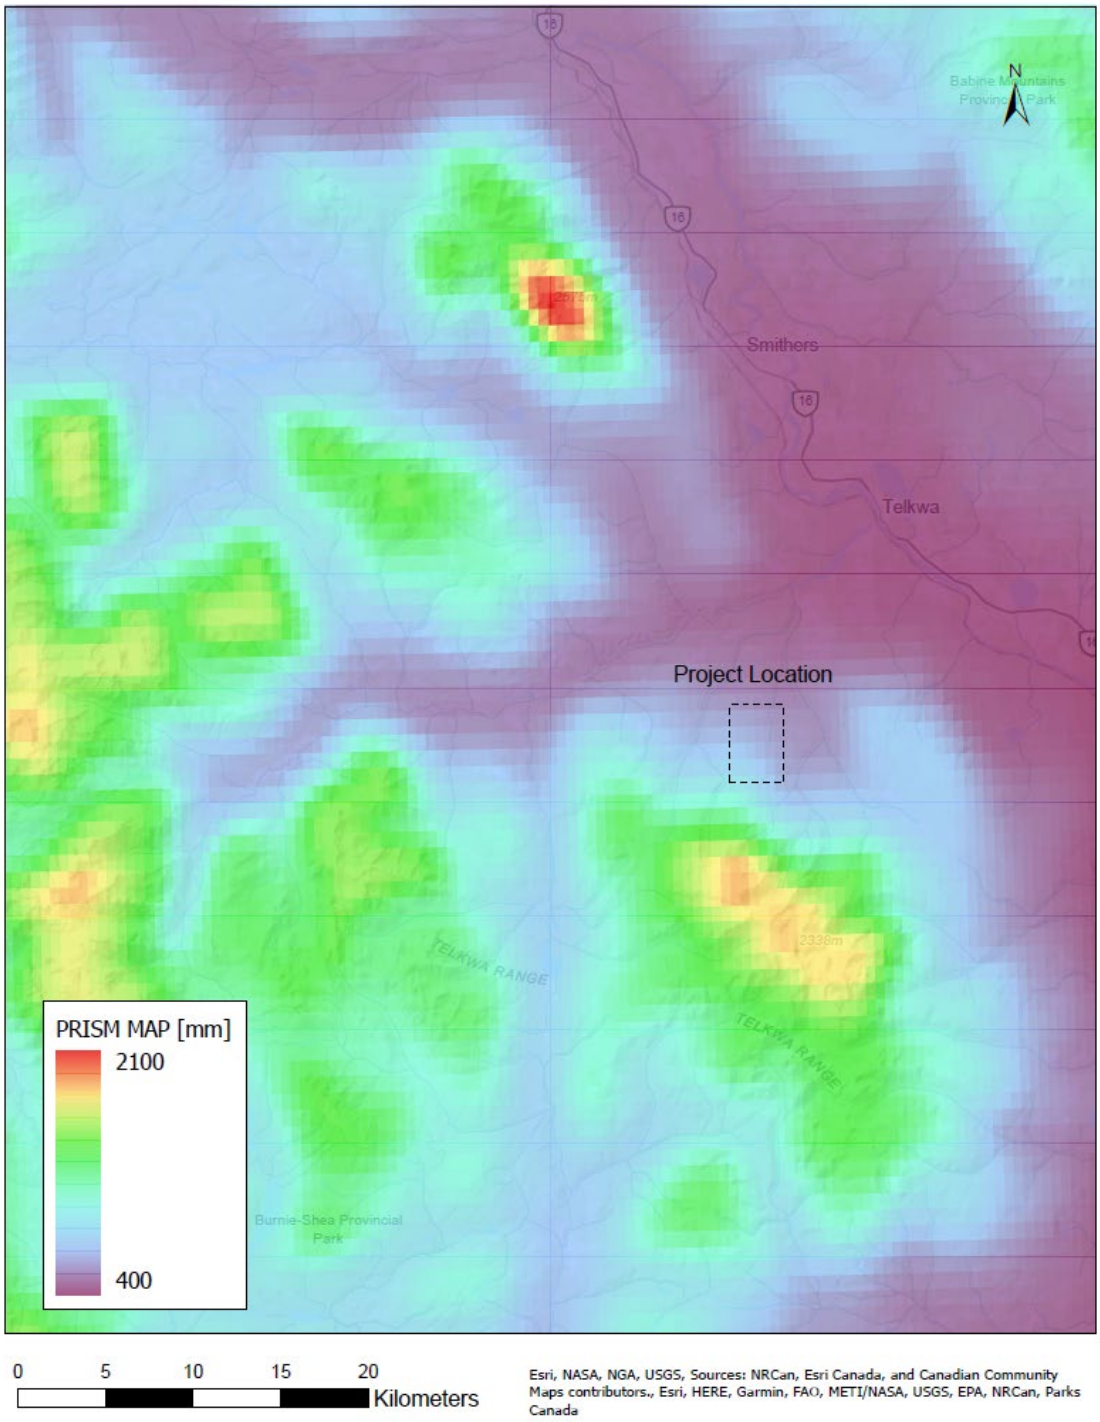

Figure 4-4: PRISM Mean Annual Precipitation in the project Area

Source: \\srk.ad\dfs\na\van\Projects\01_SITES\Telkwa Coal\1CT027.003_2020 EA Water Management\!080_Deliverables\Hydromet Baseline Update\040_Figures\Figure4.4_PRISM_MAP.pdf

4.1.3 Synthetic Extended Project Precipitation

The Smithers A station record was gap-filled using the Smithers Airport Auto station. The Smithers A station was subsequently gap-filled using the Quick station and then a quantile-mapped ERA5 reanalysis product for the Smithers A location to generate a complete time series spanning 1946-2023. The 2017-2022 Tenas Deposit station records were assessed in relation to regional station records on a monthly and daily basis. This assessment was done for hourly, daily, and monthly precipitation totals as well as seasonally by lumping multiple months together. Ultimately, the gap-filled regional time series at Smithers A was adjusted to the Project area using the linear regression provided in Figure 4-3 developed from the monthly precipitation totals (R2 of 0.65). No bias correction was undertaken to avoid overfitting the data due to the length of the overlapping period.

Table 4-4 presents the monthly precipitation measured at the Tenas Deposit station relative to the monthly modelled precipitation using the linear regression with Smithers A.

Table 4-4: Total Precipitation Measured at Tenas Deposit Station and Modelled Precipitation using Linear Regression from Smithers Airport

Year	Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual Total
2017	Total Measured Precipitation [mm]	M	M	M	M	M	M	M	M	M	147	134	10	291[1]
	Total Modelled Precipitation [mm]	-	-	-	-	-	-	-	-	112	180	134	12	439[1]
2018	Total Measured Precipitation [mm]	50	150	81	14	14	42	50	2	50	54	51	113	672
	Total Modelled Precipitation [mm]	42	81	54	7	32	72	28	2	32	54	76	69	549
2019	Total Measured Precipitation [mm]	60	19	8	13	26	57	83	21	47	93	73	22	522
	Total Modelled Precipitation [mm]	61	30	32	30	19	37	63	24	27	86	98	23	529
2020	Total Measured Precipitation [mm]	126	26	30	14	25	63	35	84	55	84	107	M	647[1]
	Total Modelled Precipitation [mm]	73	23	16	9	29	65	63	122	62	90	61	-	612[1]
2021	Total Measured Precipitation [mm]	M	M	12	14	56	51	61	24	75	31	107	29	460[1]
	Total Modelled Precipitation [mm]	-	-	33	6	26	39	38	33	100	23	96	29	423[1]
2022	Total Measured Precipitation [mm]	17	55	21	28	48	75	41	41	11	M	M	M	337[1]
	Total Modelled Precipitation [mm]	55	49	10	33	49	59	61	37	9	-	-	-	361[1]

Notes:
M denotes a month with greater than 10 (typically 20-25) days of missing data. – indicates that the synthetic data was removed over this period for meaningful comparison with measured Tenas Deposit data.

[1] Indicates that calculated annual total precipitation is for a partial year as one or more months had >10 days of missing data.

Source: compiled in text from \NA CAPR002055 Telkwa Project General EA Support - Internal\Surface Water IR Responses\Updated Responses_20230906\1CT027.003_Telkwa_ITT_SW_IRs_Round2_WaterBalanceOnly_20240603_njs_ccm df.docx

Finally, PRISM correction factors were applied to account for the elevation distribution across the Project Area. The correction factors are presented in section 4.2.5.

Table 4-5 summarizes expected average monthly precipitation at the Project based on the modelled time series. The mean annual precipitation (MAP) is estimated to be 675.9 mm which is approximately 19% greater than average precipitation recorded in the valley at the Smithers Airport station.

Table 4-5: Project Precipitation Summary [mm]

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Year
Rainfall	4.3	2.6	3.1	15.1	41.7	70.7	58.1	55.8	63.8	42.8	10.2	2.0	370.2
Snowfall	56.6	32.8	24.0	17.5	8.9	0.2	0.0	0.3	4.6	42.7	63.6	54.4	305.6
Total	60.9	35.4	27.2	32.6	50.5	70.9	58.1	56.1	68.4	85.6	73.8	56.4	675.9

4.1.4 Extreme Precipitation

4.1.5 Annual Frequency Analysis

A frequency analysis was performed using annual precipitation estimates derived from the long-term Project precipitation time series, developed using adjustments to Smithers Airport Station. The frequency analysis tested a range of probability distributions and found that a normal distribution provides the best fit to the long-term annual precipitation data for the Project.

The results of the annual frequency precipitation analysis are presented in Table 4-6 for extreme conditions ranging from a 1,000-year dry to a 1,000-year wet return periods.

Table 4-6: Annual Precipitation Frequency Analysis

Hydrological Condition	Return Period [years]	Annual Precipitation [mm]
Wet	1000	970.1
	500	950
	200	921.2
	100	897.4
	50	871.5
	25	842.6
	20	832.5
	10	798
	5	756.1
Mean Annual Precipitation (MAP)		676
Dry	5	595.8
	10	553.9
	20	519.4
	25	509.3
	50	480.4
	100	454.5
	200	430.7
	500	401.9
	1000	381.8

Source: compiled from R code \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html

4.1.6 Short-Duration Extreme Precipitation

The annual maximum daily and 3-day precipitation depths were calculated following the Regional Frequency Analysis framework proposed by Hosking & Wallis (1997). This is a refined approach compared to local frequency analysis (one station) aimed to increase the accuracy of low probability events (e.g., 1,000-year precipitation), fundamental for engineering design and risk assessment. The RFA considered as homogeneous group the following stations:

Within the RFA framework, a range of probability distributions were tested and it was found that a Generalized Extreme Value distribution provided the best fit to both the 24-hour and 72-hour datasets.

Annual maximum 1-day and 3-day precipitations were converted to maximum 24-hour and 72-hour precipitation using a factor of 1.13 and 1.04, respectively (WMO, 2009).

Table 4-7 presents the 24-hour and 72-hour precipitation depths for a range of return periods based on the RFA of the long-term Project precipitation record.

Table 4-7: Extreme Project Precipitation for 24-hour and 72-hour Events

Return Period	24-hour Precipitation [mm]	72-hour Precipitation [mm]
2	41.7	56.2
5	54.8	73.8
10	64.9	87.4
25	79.4	107.0
50	91.7	123.6
100	105.3	141.9
200	120.5	162.4
500	143.2	193.0
1000	162.7	219.3

Source: compiled from R code \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html

For durations less than 24-hours, the depth-duration-frequency curve data from the Smithers Airport station were obtained and modified to account for the 24-hour results presented in Table 4-7. Sub-daily annual maximum records from Smithers A stations were obtained from the IDF_CC Tool (Version 7.5). An IDF based on GEV distribution (Koutsoyiannis, Kozonis, & Manetas, 1998) was fitted to these records with the same shape parameter estimated in the regional approach described above for consistency. Frequency and duration factors were calculated based on the 24-hour precipitation depths for Smithers Airport, and were applied to the Project 24-hour depths presented in Table 4-7. Table 4-8 summarizes the baseline depth-duration-frequency curve for the Project.

Table 4-8: Project Baseline Precipitation-Duration-Frequency Curve

Storm Duration		Precipitation (mm)						
		Return Period (years)						
min	hours	2	5	10	25	50	100	200
5	0.08	3.5	4.7	5.5	6.7	7.8	9.0	10.2
10	0.17	4.8	6.3	7.5	9.1	10.5	12.1	13.8
15	0.25	5.7	7.5	8.9	10.9	12.6	14.4	16.5
30	0.5	7.7	10.2	12.0	14.7	17.0	19.5	22.3

4.1.7 Probable Maximum Precipitation

The probable maximum precipitation (PMP) was calculated using the Hershfield methodology (WMO 2009), and the Project-adjusted precipitation record. The Canadian Dam Association Guidelines (2007) recommends evaluating two Probable Maximum Floods (PMF):

Summer/autumn PMF, which is generated by the summer/autumn PMP

Spring PMF is defined as the maximum of two cases:

1. PMF computed with Spring PMP and snow accumulation with frequency of 100 year (Rainfall Dominated)
2. PMF computed with the Probable Maximum Snow Accumulation (PMSA) and a rainstorm with a frequency of 100 year (Snowmelt Dominated)

Two separate PMFs are estimated for the Spring season as it is not reasonable to assume that the PMSA and a Spring PMP, which are two independent phenomena, would occur simultaneously.

Based on the typical hydrograph for the Project (see Section , snow at the Project is expected to be present until as late as June.

Table 4-9 presents the Spring and Summer/Autumn PMPs for the Project where Spring was defined as April to June and summer was defined as July through October.

Table 4-9: Project 24-hour Probable Maximum Precipitation

Season	PMP (mm)
Spring	234
Summer/Autumn	283

Source: compiled in text from R code \\srk.ad\dfs\na\van\Projects\01_SITES\Telkwa Coal\1CT027.003_2020 EA Water Management\200_Meteorology_Update\R work\Telkwa_EA_Precipitation_1CT027.003_rev01.Rmd

Results were verified using the British Columbia MetStorm Probable Maximum Precipitation webtool (DTN, 2020), which was developed in support of the BC Extreme Flood Project. This web-based tool provides an indication of potential precipititaion depths based on regionally available datasets at select points across the province. The maximum point PMP estimated from the webtool within the Project vicinity is 218 mm. The results in Table 4-9 are based on Project-specific precipitation datasets and present a more conservative PMP estimate. For this reason, the Project data were used for the purpose of infrastructure design.

4.1.8 Snow Depth and Snowmelt

The SNOW-17 snow accumulation and ablation model developed by the National Weather Service River Forecast System (NWSRFS) was implemented to model snowmelt for the Project. The main processes included in this model are dividing precipitation into rain or snow, accumulation of snowpack, energy exchange, heat deficit in the snowpack, ground melt and snowmelt as a snow water equivalent (Anderson 2006). Model inputs are average temperature and precipitation and input parameters to model a column of snow. The Project weather station recorded an accumulated depth of snow. Data collection at the Project did not include snow courses or snow density to convert snow depth to snow water equivalent (SWE) but regional estimates were used to check the SNOW-17 model accuracy.

Table 4-10 summarizes the model input parameters based on guidelines of initial estimates (Anderson 2002) and validation against the snow water equivalent records at Tsai Creek. Temperature and precipitation time series for the Tsai Creek elevation were developed using PRISM corrections. Figure 4 illustrates the measured and modelled snow water equivalent snow depths at Tsai Creek.

Table 4-10: SNOW-17 Model Input Parameters

Parameter	Description	Value
PXTEMP	Temperature threshold	Linearly interpolated between: 100% snowfall (and 0% rainfall) at 1.5 °C 0% snowfall (and 100% rainfall) at 5 °C
SCF	Loss coefficient during period of snow (i.e. sublimation)	1
UADJ	Average wind function during rain-on-snow events	0.04 mm/mbar/hr
MBASE	Temperature above which melt occurs	0 °C
MFMAX	Maximum melt factor	0.51 mm·°C·6hr^{-1}
MFMIN	Minimum melt factor	0.10 mm·°C·6hr^{-1}

The validation with Tsai Creek suggests the snowmelt timing is well captured, with some understimations of maximum snowpack. This may be a result of inaccuracies in the precipitation record estimated for Tsai Creek. For the purpose of water management planning and design and water balance modeling, the SNOW-17 model and inputs were applied to the Project. Figure 4-7 illustrates the average snow water equivalent depths for the Project based on the adjusted precipitation and temperature records from 1942 to 2020.

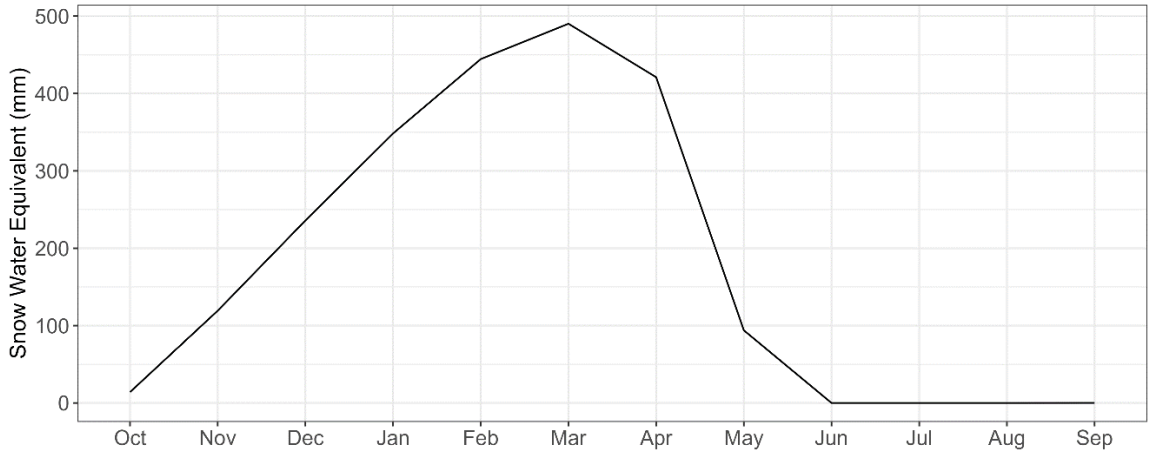

Figure 4-7: Project Snow Water Equivalent

Source: Compiled from R code \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html

In addition to snow-water-equivalent, the snowmelt model produces a daily excess water term, which represents the sum of rainfall and snowmelt and can be interpreted as the daily depth of water available to generate runoff. Table 4-11 presents the monthly average excess water results for the Project, along with the monthly average distribution.

Table 4-11: Project Excess Water Monthly Average Summary [mm]

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Ann
Total Excess Water	2	3	18	145	184	70	58	54	67	60	9	2	672

4.1.9 Solar Radiation

Given the short period of record at the Tenas Deposit Station and large differences to Smithers Airport Station, the FAO model (Allen et al. 1998) was adopted to calculate historical baseline averages of solar radiation using the corrected temperature timeseries developed for the Project (Table 4-13). The appropriateness of the FAO model to approximate incoming solar radiation at the Tenas Deposit Station was illustrated from October 2017 to September 2022 in Figure 4-8.

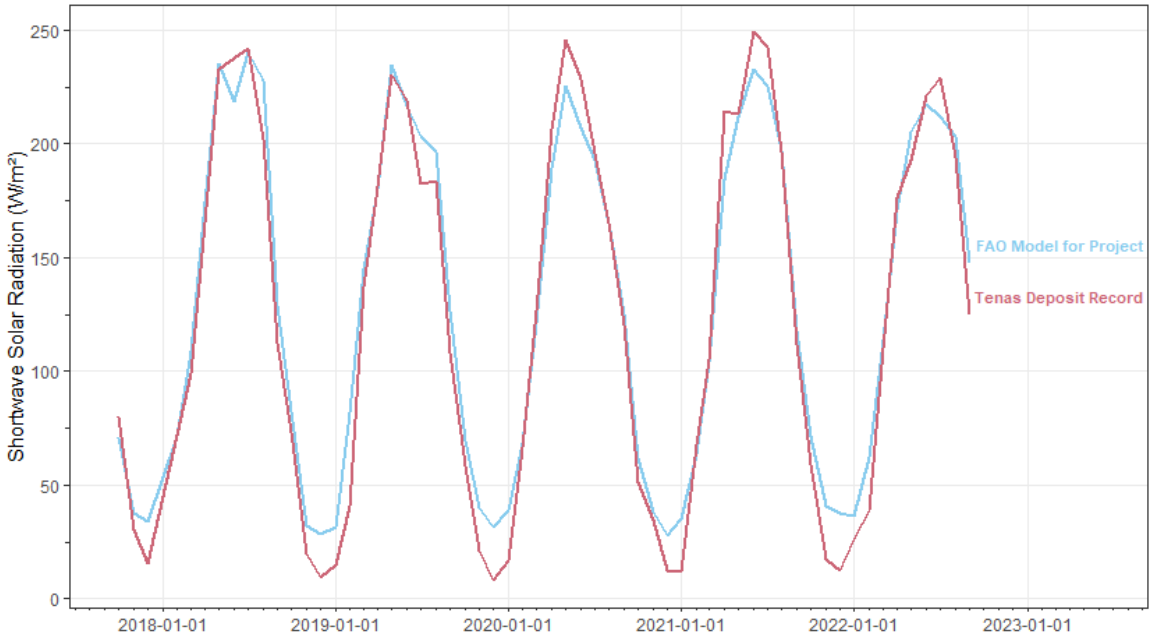

Figure 4-8: Solar Radiation – Modelled versus Measured (October 2017 to September 2022)

Source: Compiled from R code \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\02 - Climate Review.html

4.1.10 Relative Humidity

Given the short period of record at the Tenas Deposit Station and the similarities observed between Smithers Airport Station records presented in Section 2.3.6, Smithers Airport station relative humidity was applied to the Project. Table 4-14 presents the monthly average relative humidity for the Project.

Table 4-14: Average Monthly Relative Humidity [%] at Project

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
Average (%)	83.6	79.3	71.2	63.3	61.3	65.7	68.8	72.1	79.5	82.1	85.9	85.4	74.8

4.1.11 Evaporation

Large and shallow water bodies can experience direct water losses from evaporation. Lake surface evaporation for the Project was estimated using the Morton CRWE shallow lake evaporation method (Morton 1983). Table 2-18 summarizes the input parameters required for this method including the Project-specific solar radiation generated using the FAO model.

Based on the adjusted temperature record, modelled solar radiation and relative humidity and wind speeds from the Smithers Airport station, the estimated mean annual evaporation for the Project is 529 mm. Table 4-15 and Figure 4-9 demonstrate the mean open water evaporation rates for the Project. The potential evaporation estimates generated using the Morton CRWE results for the derived Project timeseries were closest to the Topley Landing Normals.

Table 4-15: Project Monthly Total Lake Evaporation [mm]

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Year

4.2 Derived Hydrological Parameters

4.2.1 Time Series Comparison

Comparisons of the unit discharge at each Project hydrometric station with regional station data records led to pairing of the Project record with the most appropriate regional analogue (Table 4).

Regression approaches were used for the periods of overlap between each of the Project hydrometric stations and their respective regional analogue. In the case of Goathorn-Hydro, a catchment area scaling approach was used instead of regression methods. Time series of Project Area and regional station unit discharge records for Goathorn-Hydro and Goathorn Creek (08EE008), Telkwa-Hydro and Telkwa River (08EE020) Tenas-Hydro B and Goathorn Creek (08EE008), and Four-Hydro and Goathorn Creek (08EE008) are shown in Figure 4-10, Figure 4-11, Figure 4-12, and Figure 4-13, respectively. Additional comparisons for Four Creek based on 1999 baseline data are also described.

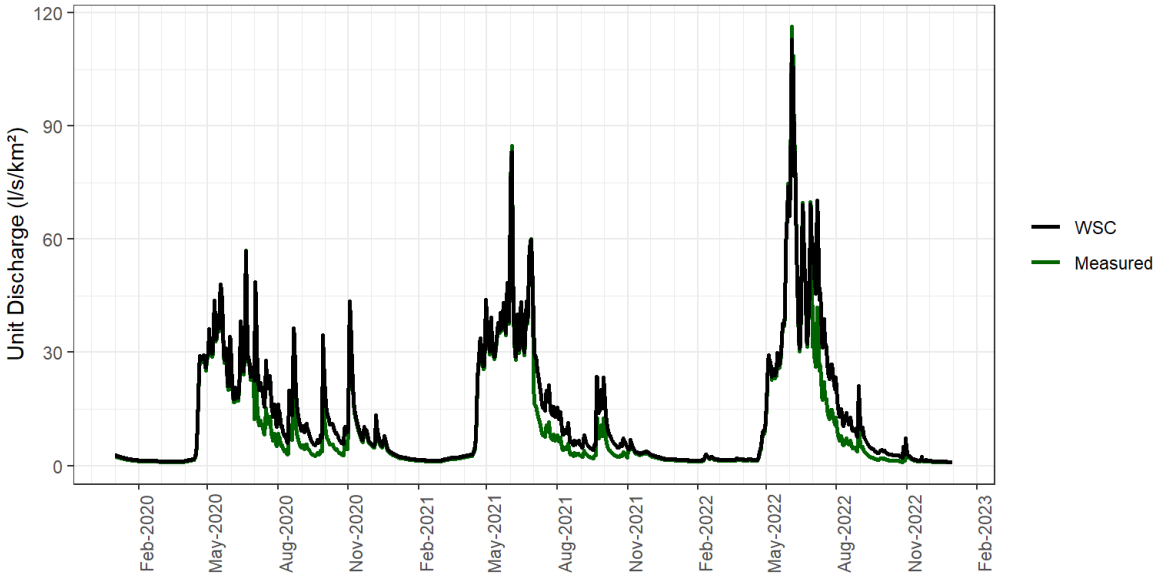

Figure 4-13: Project Hydrometric Station Four-Hydro (green-Measured) and Water Survey of Canada Goathorn Creek Near Telkwa (08EE008) (black-WSC)

Source: \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\01 - Flow Review.html

A previous investigation into the hydrology of Four Creek was completed in 1997 (October to November) to 1998 (June to November) to support the Telkwa Coal Project 1999 Baseline Surface Flow and Water Quality Final Data Report (AGRA, 1999; Attachment A). The precise location of the AGRA hydrometric stations are not known, which limits the transferability of analyses using historical data. Based on the station descriptions in AGRA 1999, approximate locations were estimated and catchment areas were calculated.

Unit flows and monthly runoff rates were calculated based on assumed catchment areas and compared between Tenas, Four and Goathorn creeks, presented in Table 4-16 and Figure 4 and described in Attachment A and in tabular form in Attachment C. Runoff rates by month show a lower yield in Four Creek than in Tenas Creek, and higher rates in Goathorn Creek than in Tenas Creek during summer months of August and September. Unit flows in October 1997 show a storm response peak flow in all three streams, while 1998 records show a consistently lower yield in Four Creek than in Goathorn Creek.

Table 4-16: Comparison of Monthly Runoff Rates based on Hydrometric Data from AGRA 1999 at Goathorn, Tenas and Four Creeks (Attachment A, C)

Stream	Year	Runoff (mm/month)											
		Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Tenas Creek	1997	ND	ND	ND	ND	ND	ND	ND	22	12	47	ND	ND
	1998	ND	ND	ND	ND	40	ND	ND	5	8	11	ND	ND
Four Creek	1997	ND	ND	ND	ND	ND	ND	ND	ND	ND	9	4	ND
	1998	ND	ND	ND	ND	ND	ND	3	1	1	2	ND	ND
Goathorn Creek	1997	4	5	5	49	166	142	88	54	32	46	16	6
	1998	3	3	4	28	145	68	50	25	16	27	12	6

Notes:
1. Monthly runoff is calculated for months containing greater than 25 days of runoff data
2. ND: No Data or less than 25 days with data in a month

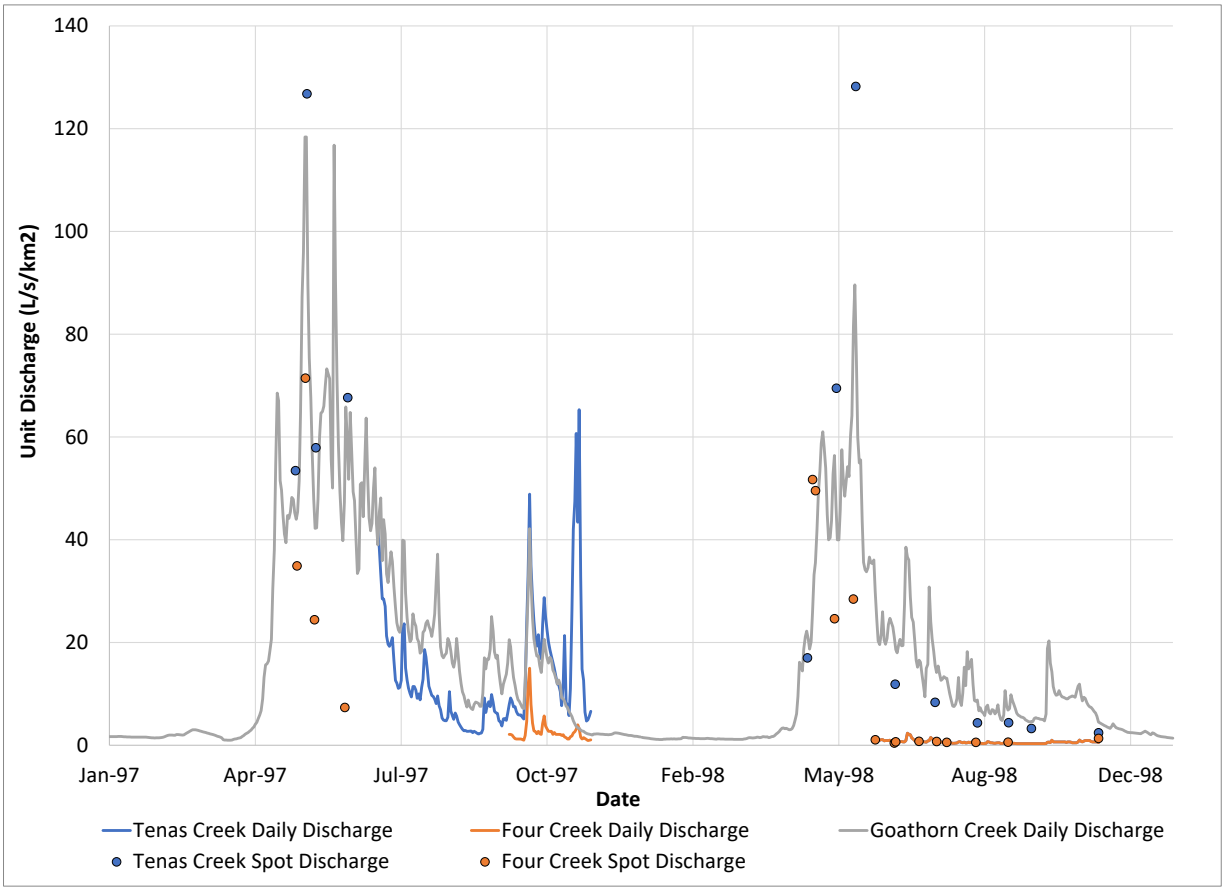

Figure 4-14: Comparison of Unit Flows based on Hydrometric Data from AGRA 1999 at Goathorn, Tenas and Four Creeks (Attachment A, C)

AGRA 1999 describes runoff ratios, based on annual runoff yield and annual precipitation data from Smithers Airport. The runoff ratios for WSC's Goathorn Creek station were calculated as 0.65 and 0.83 in 1997 and 1998, respectively, and 0.28 in both years for Four Creek. Note that results from Section 4.1.2 show that precipitation data from Smithers Airport is expected to be distinct from precipitation that falls near the Telkwa Project Area or within each stream's

catchment, limiting the applicability of these ratios. This discrepancy is also noted in AGRA 1999. AGRA 1999 stated that the difference in runoff ratios between Goathorn and Four Creek could be attributed to potential orographic gradients in precipitation and the difference in the altitude range between Goathorn Creek (1745 m, from 550 to 2295 masl) versus Four Creek (670 m from 700 to 1370 masl). The Four Creek basin generally faces the northeast, where as the Goathorn Creek basin faces northeast and northwest, which is expected to cause differences in snowpack accumulation and ablation (AGRA 1999). AGRA also concluded that groundwater baseflows would be more pronounced in Goathorn Creek as it extends lower in the basin than Four Creek, which may result in an increased occurrence of springs surfacing from fractures.

4.2.2 Model Development

The regression approach ultimately selected to develop regressions between measured, Project hydrometric records and regional analogues was chosen based on: (1) The simplicity of the regression, (2) the Nash-Sutcliffe Efficiency (NSE) between the estimated flows and the measured flows for the period of overlap and (3) the ability of the regression to approximate both high and low flows based on flow duration curves. The regressions were then used to generate synthetic flow records for each Project hydrometric stations using the long-term, regional records from Water Survey of Canada as a foundation. The time series generated from the developed regression equations for each hydrometric station were compared to the measured unit discharges at each station using tables.

In the previous version of the Tenas Project hydrology baseline, provisional data from Goathorn Creek Water Survey of Canada (WSC) (Station ID: 08EE008) had been used to develop regressions between site data and WSC Goathorn data and ultematly generate the site synthetic records. Provisional data previously used in the baseline study has been updated and published data is now available online through December 2021 while the 2018 record has been removed.

Table 4 summarizes the pairings between Project hydrometric stations and the most suitable regional analogue, catchment areas for each station and the NSE from the model. A catchment area scaling approach was used for Goathorn-Hydro instead of regression methods due to both stations measuring the same water course with similar catchment areas.

Table 4-17: Project and WSC Regional Prediction Type and Fit Parameter

Project Station ID	Project Station Catchment Area (km^2)	Regional Station ID	Regional Catchment Area (km^2)	Model	NSE
Goathorn-Hydro	123.5	Goathorn (08EE008)	125	Catchment area scaling	0.94
Tenas-Hydro B	46.8	Goathorn (08EE008)	125	Linear Regression, Chronological Pairing	0.85
Telkwa-Hydro	997.2	TelkwaBTC (08EE020)	367	Ranked Regression, Time-independent	0.96
Four-Hydro	11.0	Goathorn (08EE008)	46.8	Ranked Regression, Time-independent	0.54

Source: Compiled in text.

Goathorn-Hydro

A catchment area scaling approach was pursued to adjust the streamflow from WSC Goathorn station to Goathorn-Hydro station. The catchment area of WSC Goathorn station (125 km²) is 1.2% larger than the catchment area of the site station (123.5 km²), so its flows were reduced by 1.2%. The site data was extended with the adjusted WSC Goathorn data. The event recorded at Goathorn-Hydro on 25 October 2017 event was removed from the dataset as its occurrence was not supported by any similarly large discharge event recorded at the Water Survey of Canada Goathorn station. During the period when both stations had overlapping records, the recorded daily average unit flow at Goathorn-Hydro was 17.1 L/s/km^2 while the WSC Goathorn station recorded 18.5 L/s/km^2. Figure 4-15 shows the regression of the unit discharge between the two Goathorn stations.

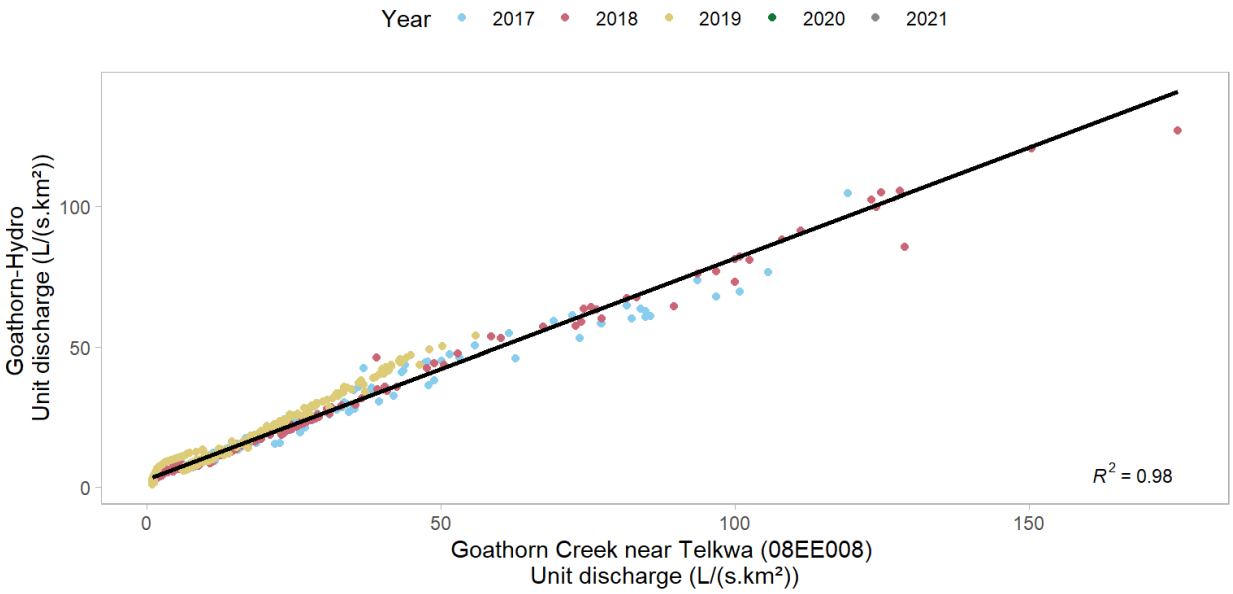

Figure 4-15: Linear regression showing measured Goathorn-Hydro unit discharge relative to WSC Goathorn Creek Near Telkwa (08EE008) unit discharge

Source: \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\01 - Flow Review.html

Table 4-18 shows the unit discharge measured at Goathorn Hydro compared to the unit discharge calculated from the area scaling model for the same time period each year. The measured unit discharge and the estimated values are very similar with slight overestimation in 2017 and 2018 and some underestimation in 2019.

Exceedance probabilities of the measured and estimated unit discharge are presented in Figure 4-16, which shows that estimated flows are very similar in magnitude for average and high flows. The estimated unit discharge for high exceedace probabilities (low flows) is lower than the measured values.

Table 4-18: Measured and Estimated Unit Discharge Values at Goathorn-Hydro

Year	Month	Goathorn-Hydro Unit Discharge (L/s/km^2)	Annual Average (L/s/km^2)	Estimated Unit Discharge (L/s/km^2)	Annual Average (L/s/km^2)

Tenas-Hydro B

The Tenas-Hydro B station was paired with Goathorn Creek Near Telkwa (08EE008) for developing a regression to develop a synthetic time series. The linear regression was separated into two periods, based on the month, as shown in Figure 4-17.

Table 4-19 shows the unit discharge measured at Tenas Hydro compared to the unit discharge calculated from the regression equations for the same time period each year. Each year presents similar annual average flows.

Exceedance probabilities of the measured and regressed unit discharge are presented in Figure 4 which shows that estimate flows are very similar in magnitude for low and high flows, with extreme low flows being slightly overestimated in the synthetic dataset.

Table 4-19: Measured and Regressed Unit Discharge Values at Tenas-Hydro B

Telkwa-Hydro

The Telkwa-Hydro hydrometric data was regressed against Water Survey of Canada Telkwa River Below Tsai Creek (08EE020) using ranked regressions, which uses paired discharge records independent of chronological order. Monthly ranked regression results are presented in Figure 4-19, and regression equations with goodness of fit indicators are presented in Table 4-20.

Table 4-21 presents the unit discharge measured at Telkwa Hydro compared to the unit discharge calculated from the monthly regressions with Telkwa River Below Tsai Creek for the same time period each year. The regressed values underestimated flow in 2017 but provided similar results for 2018 and 2019.

Exceedance probabilities of the measured and regressed unit discharge are presented in Figure 4-19 which shows that estimated flows are very similar in magnitude for average and high flows, but less accurate for low flows (higher exceedance probability results), where the estimated results are lower than the measured values.

Four-Hydro

The Four-Hydro hydrometric data was regressed against Water Survey of Canada Goathorn Creek Near Telkwa (08EE008) flows using ranked regressions (Figure 4-21), which uses paired discharge records independent of chronological order.

Linear chronological pairing was assessed, but a good relationship with regional stations was not obtained. A ranked regression was then developed without grouping the data by month, as done for Telkwa-Hydro. In fact, the low availability of flow records in some months hindered this more refined type of regression for Four-Hydro station. Despite this, the regression undertaken provides valuable insight that the unit flows measured in Four-Hydro are smaller than the other stations, so assuming other station as analog without a bias correction may impose an overestimation of flows in Four-Hydro.

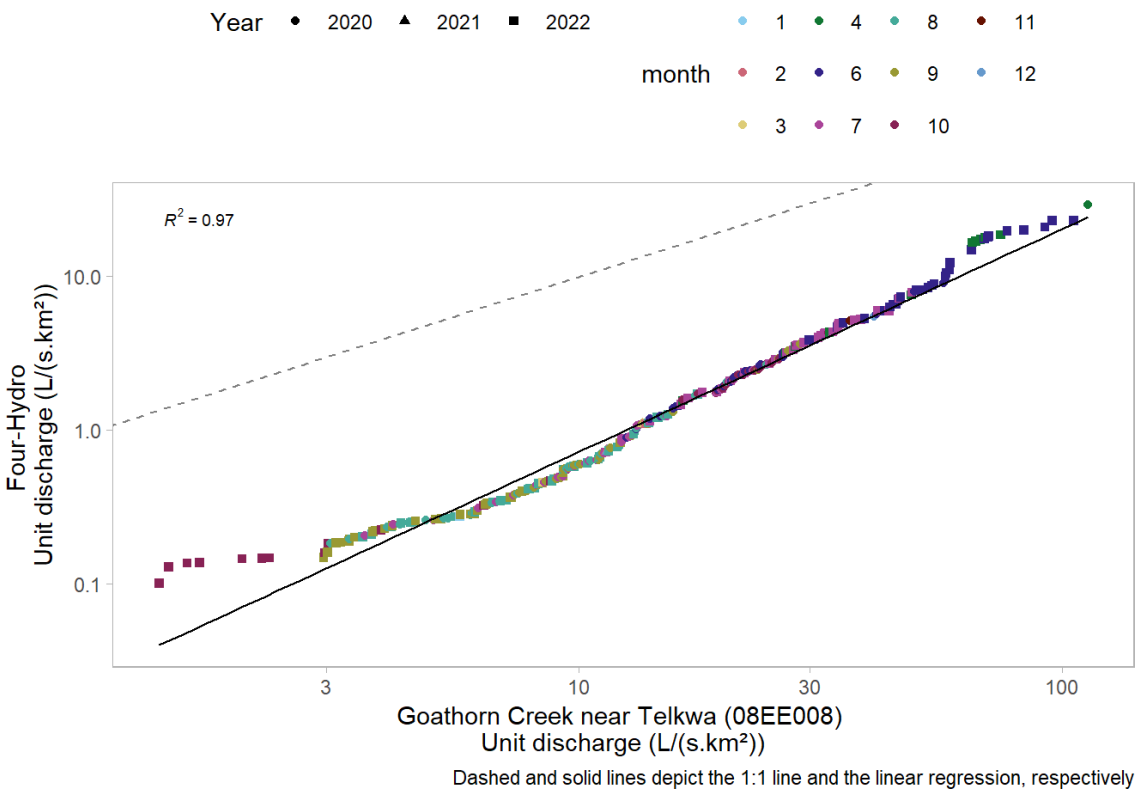

Figure 4-21: Ranked regression between WSC Goathorn Creek Near Telkwa (08EE008) station and Four-Hydro station

Source: Compiled from R code \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\01 - Flow Review.html

Exceedance probabilities of the measured and regressed unit discharge at Four-Hydro are presented in Figure 4-22, which shows that estimated flows are representing well medium flows, but underpredicting high and low flows.

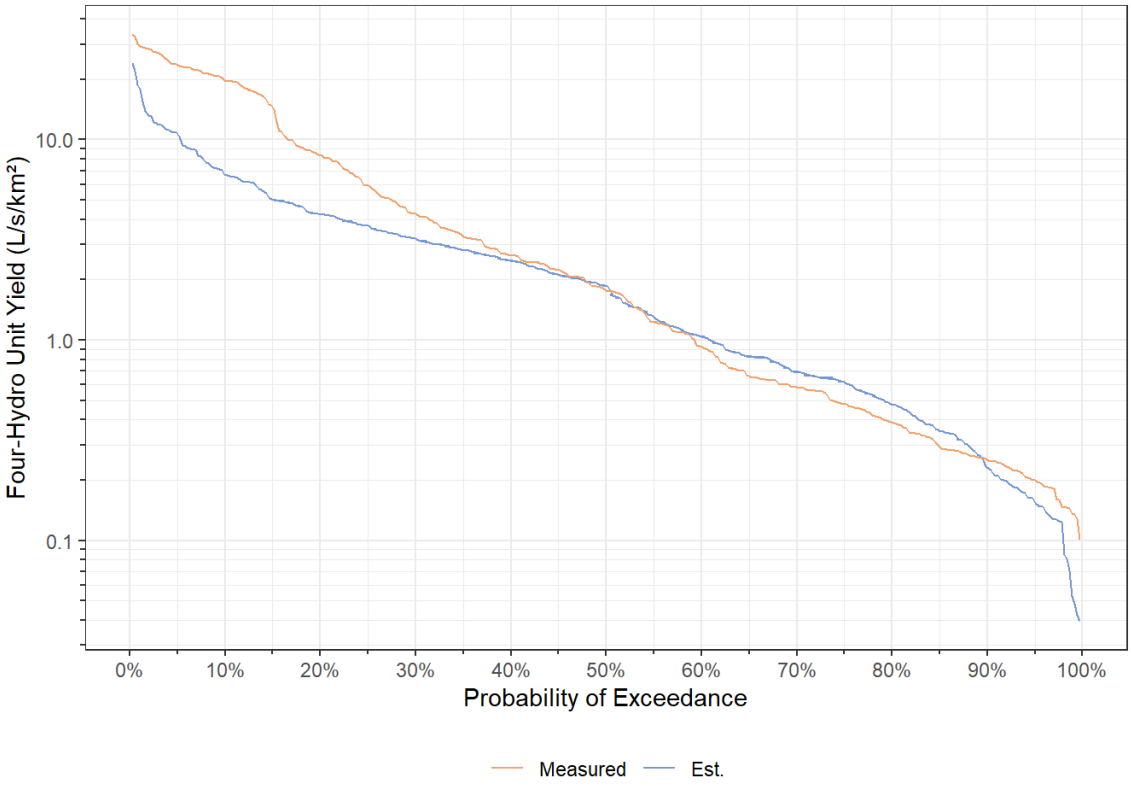

Figure 4-22: Probability Exceedance of Unit Discharge (L/s/km²) at Four-Hydro

Source: Compiled from R code \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\01 - Flow Review.html

Table 4-22 presents the unit discharge measured at Four Hydro compared to the unit discharge calculated from the regression with WSC Goathorn Creek (08EE008) for the same time period each year. The regressed values underestimated average and high flows, but remained close to the measured low flows.

4.2.3 Extended (Synthetic) Time Series for Project Hydrometric Stations

The regressions developed for Goathorn-Hydro, Telkwa-Hydro, Tenas-Hydro and Four-Hydro were used to generate a long-term, extended (synthetic) time series based on the Water Survey of Canada regional records. The synthetic unit discharge time series are shown in Figure 4-23 for Goathorn-Hydro, Figure 4-24 for Telkwa-Hydro, Figure 4-25 for Tenas-Hydro B and Figure 4-26 for Four-Hydro.

Table 4-23, Table 4-24, and Table 4-25 present the monthly average streamflow, unit flow, and runoff yield for each hydrometric station based on the extended time series results. These averages are based on a 30-year record, frin 1993 to 2022, consistent with best practice.

4.2.4 Baseflow separation

The rate at which groundwater discharges into surface streams was characterized using a recursive digital filter to separate baseflow from surface runoff. A single filter parameter, typically ranging from 0.9 to 0.99 based on visual observations was incorporated to separate total streamflow into a baseflow component and surface runoff component for each of the local and regional hydrometric stations. In this method, the filter is passed over the data 1 to 3 times, where the more passes processed results in a more consistent seasonal baseflow value. Flow records from 2000 to 2019 were used in the separation model, and an upper range of filter parameters were incorporated to simulate a uniform baseflow regime with reduced peaks. A series of parameter combinations were tested, and select results are presented in Attachment B, showing baseflow and total flow from 2010 to 2015. A filter parameter of 0.99 was selected with three passes (n=3).

Monthly average baseflows were calculated over the 19-year modelled period for Four-Hydro, Tenas Hydro, Telkwa Hydro, Goathorn Hydro and Bulkley River at Quick (WSC) based on the selected filter parameter inputs. Unit baseflows were calculated by dividing by respective catchment areas and are presented in Table 4-26.

Table 4-26: Unit Baseflows (L/s/km^2) for Each Major Stream within Project Area

Month	Bulkley	Telkwa	Goathorn	Tenas	Four

4.2.5 Rainfall-Runoff Model Configuration

Surface runoff is defined as the total amount of surface water discharged from a watershed and is frequently presented as the depth of water distributed evenly throughout the watershed area. The Project is located within the Goathorn Creek, Tenas Creek and Four Creek watersheds.

A daily rainfall-runoff model was generated to support streamflow estimations in the water and load balance model and to provide Project-specific runoff rates. The runoff model for the Project Area was developed using a snowmelt model (see Section 4.2.4), a minimum baseflow function, a lag time, recession coefficient and monthly runoff coefficients for each of the main catchments. Monthly runoff coefficients were calibrated automatically within GoldSim by optimizing the Nash Sutcliffe Efficiency, based on the difference between observed and modelled daily flow.

The model required long-term precipitation and temperature inputs for the same period as the synthetic streamflow datasets. The long-term Project temperature and precipitation records were adjusted using PRISM datasets to estimate climate parameters for each of the hydrometric stations. An average monthly precipitation for each hydrometric station watershed was derived from the gridded PRISM monthly precipitation model. These monthly precipitation values were compared against the monthly precipitation estimates for the Project, and a ratio was calculated for each month and each station (Table 4-27).

Table 4-27: Monthly Precipitation Correction Factors applied to Project Precipitation based on PRISM

Month	Tenas Hydro	Four-Hydro	Goathorn Hydro	Telkwa Hydro	Bulkley Hydro
Jan	2.26	1.30	1.92	2.07	1.71
Feb	2.05	1.19	1.74	1.89	1.81
Mar	2.45	1.42	2.07	2.29	2.06
Apr	2.15	1.39	1.93	2.05	1.81
May	1.42	1.04	1.25	1.31	1.12

A similar process was employed for temperature. A monthly average temperature for each hydrometric station watershed was derived from the gridded PRISM monthly temperature model. These monthly temperature values were compared against the monthly temperature estimates for the Project, and a correction addend was calculated for each month and each station (Table 4-28).

Table 4-28: Monthly Average Temperature Correction Addends (in degrees Celsius) applied to Project Average Temperature based on PRISM

Source: SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\Runoff Models\Rev2_Nov 2023\Summary_Models_20241105_rev0_jls.xlsx

Using the daily temperature and precipitation time series adjusted for each streamflow station, the remaining runoff model inputs were calibrated in order to mimic the long-term synthetic streamflow records. Calibrated inputs included monthly runoff coefficients, baseflow, lag time and recession value.

Figure 4-27 illustrates the observed and modelled flows at the Goathorn-Hydro station from August 1990 to December 2021. Results produced an average Nash Sutcliffe Efficiency (NSE) of approximately 0.42 . The modelled flow resembles the synthetic record derived from the Water Survey of Canada station flows, however, peaks in modelled flows occasionally exceed the peaks observed in the synthetic and Water Survey of Canada observed flow record.

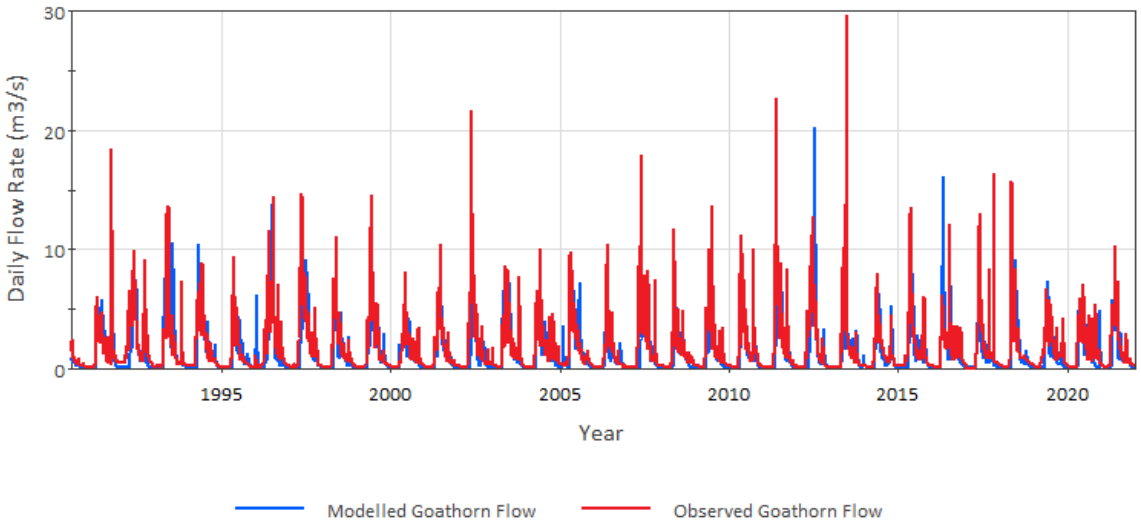

Figure 4-27: Rainfall-Runoff Model Calibration for Goathorn Creek

Source: \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\Runoff Models\Rev2_Nov 2023\Telkwa_FlowCalibrationModel_Goathorn_v6_20231124

This process was repeated for Tenas Creek. Monthly runoff coefficients were calibrated automatically within GoldSim by optimizing the Nash Sutcliffe Efficiency, based on the difference between observed and modelled daily flow.

Figure 4-28 illustrates the measured and modelled flows at the Tenas-Hydro B station from 2017 to November 2022. Results produced an average Nash Sutcliffe Efficiency (NSE) of approximately 0.47. At this location, observed data is superimposed atop modelled flow with records from Tenas-Hydro and Tenas-Hydro B. The modelled flow record shows an underestimation of synthetic and measured flow at the Tenas-Hydro B location along Tenas Creek. Derivation of runoff coefficients was tested over multiple periods to ensure that the rainfall-runoff model flow results were as representative as possible. The rainfall-runoff model currently underestimates flows and should be revisited once more flow data is available from the Tenas-Hydro station.

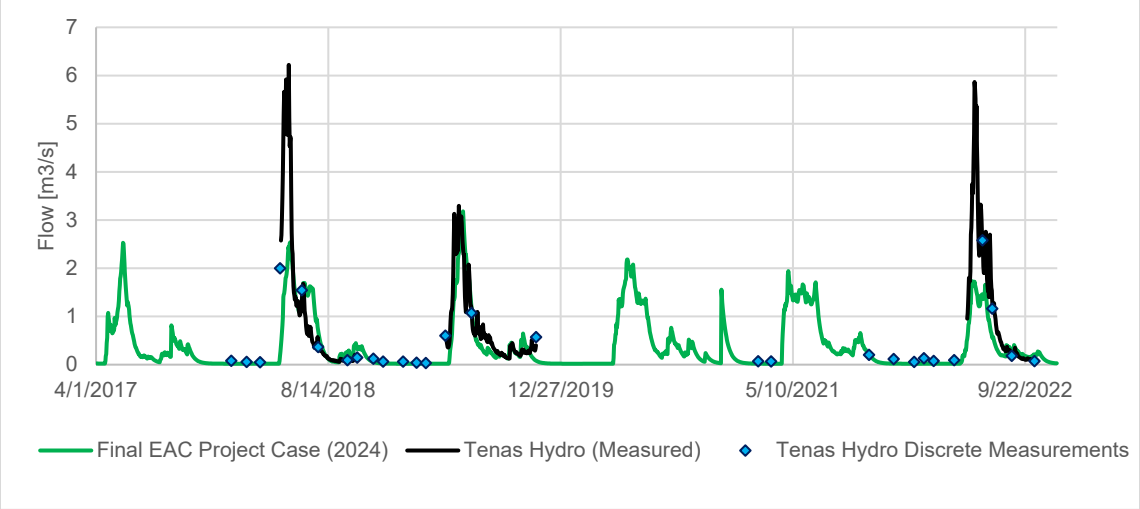

Figure 4-28: Rainfall-Runoff Model Calibration for Tenas-Hydro B

Source: \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\Runoff Models\Rev2_Nov 2023\Updated RainfallRunoff Results_20231124_rev01_njs.xlsx

The Bulkley River rainfall-runoff model for 2000 to 2018 resulted in a NSE value of 0.74 (Figure 4-29). The flows produced by the Bulkley River rainfall-runoff model show good correspondence with the observed flows at the Water Survey of Canada hydrometric station. For most of the observed flow record spanning 2000 to 2018, the modelled flows match or exceed peak flows. In some years, the model underestimates peak flows although the hydrograph shape remains similar despite the difference in magnitudes.

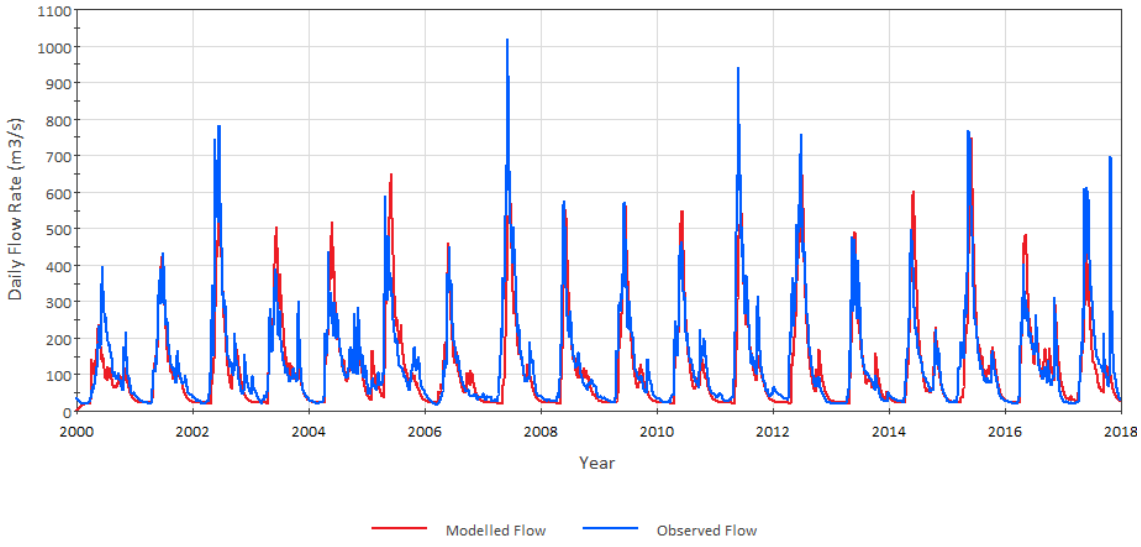

Figure 4-29: Rainfall-Runoff Model Calibration for Bulkley River

Source: \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\Runoff Models\Rev2_Nov 2023\Telkwa_FlowCalibrationModel_Bulkley_v2_2000-2018_20200421.gsm

The Telkwa-Hydro rainfall-runoff model is shown in Figure 4-30 for 2016 to 2022 with a NSE of 0.55. The modelled flows correspond well with the observed flow record generated for the Telkwa-Hydro station. The observed and modelled flows are typically similar in both magnitude and shape although the modelled flow can recede more quickly post-freshet than the synthetic record leading to lower flows in early summer.

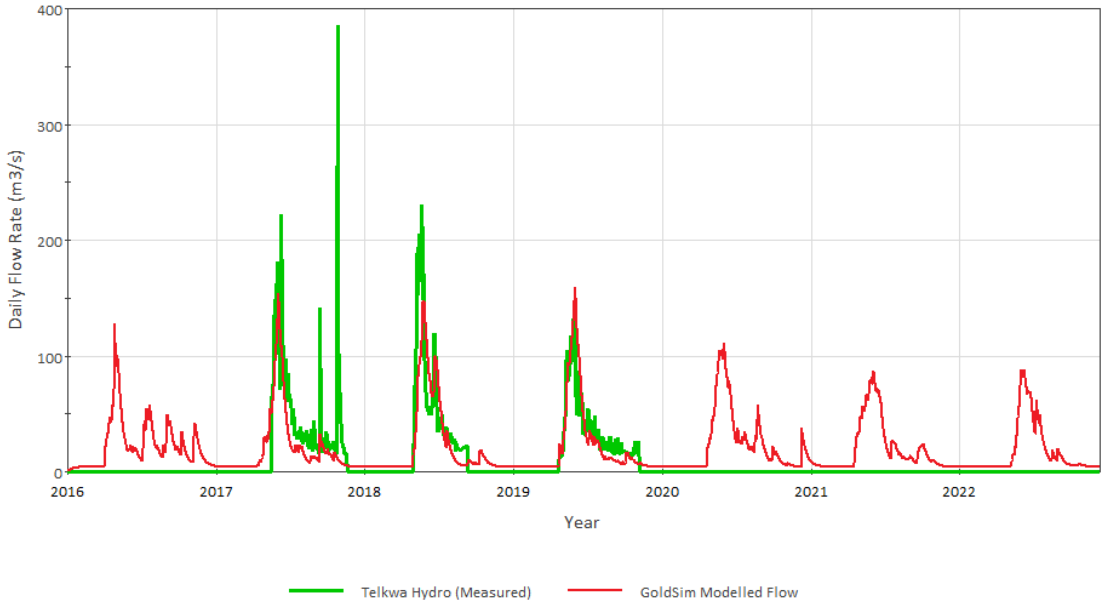

Figure 4-30: Rainfall-Runoff Model Calibration for Telkwa River

Source: \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\Runoff Models\Rev2_Nov 2023\Telkwa_FlowCalibrationModel_Telkwa-Hydro_v3_20200430_20240211.gsm

Calibration of Four-Hydro was conducted using the available 2020 and 2022 records. The continuous flow record in Four Creek from 1997 and 1998 did not include spring freshet (October and November 1997 and July through October 1998). For this reason, the data was not used in the model calibration. With only few flow records available, the monthly runoff coefficients are specific to the period used for calibration. Figure 4-31 presents the modelled and measured Four-Hydro flows. The calibration resulted in a NSE value of 0.64.

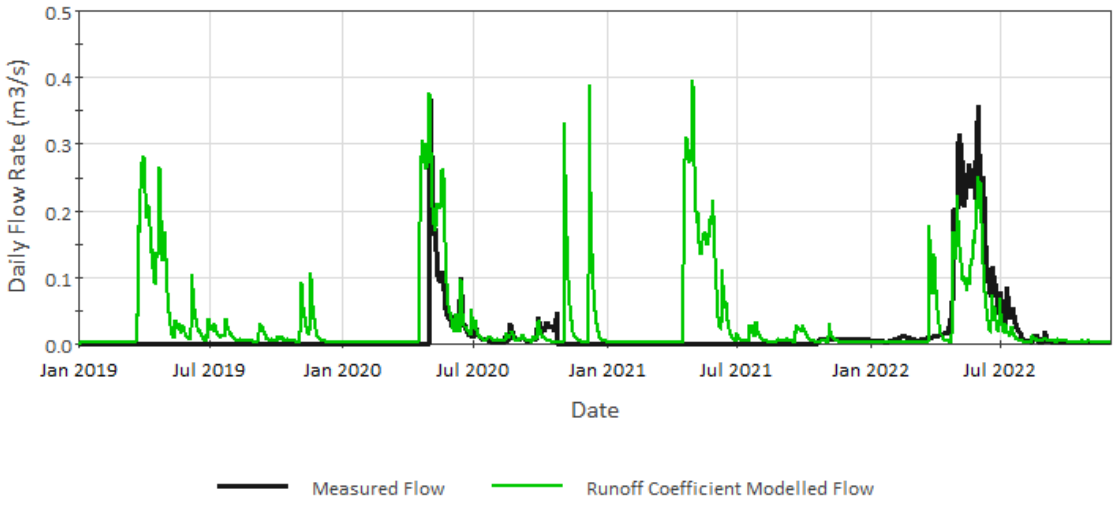

Figure 4-31: Rainfall-Runoff Model Calibration for Four Creek

The synthetic long-term Project precipitation and temperature records were incorporated to the snowmelt and runoff model to generate Project-specific runoff rates using the calibrated values from Tenas, Four and Goathorn Creek. Figure 4-32 presents the monthly average runoff distribution based on the 41-year synthetic record (1981-2021), which produced a mean annual runoff (MAR) of 242 mm. Based on the mean annual precipitation calculated for the Project, the annual runoff coefficient is equal to 0.36.

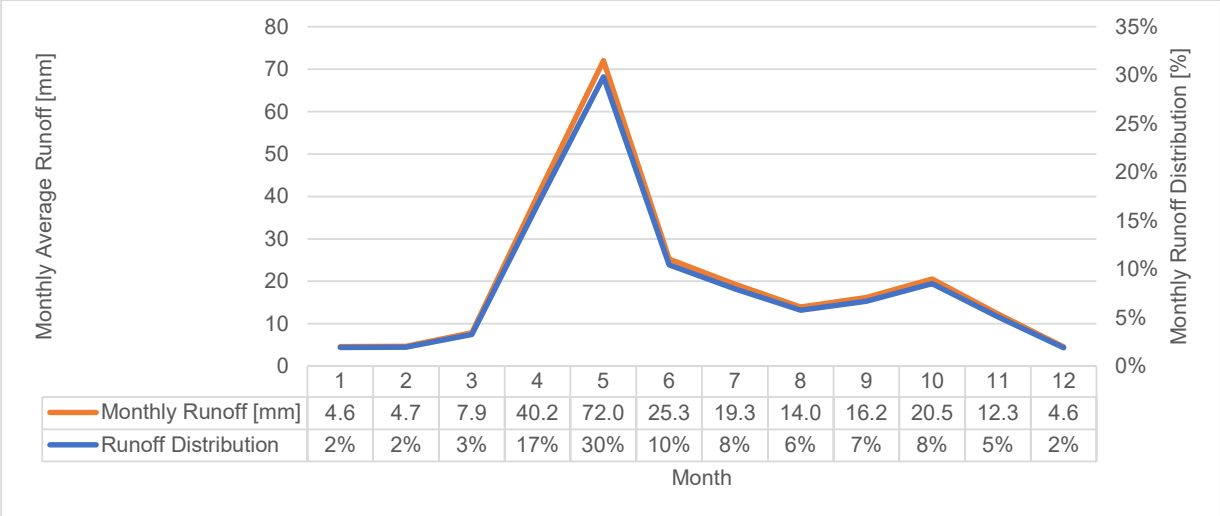

Figure 4-32: Project Area Monthly Average Runoff Depth [mm] and Distribution

Source: \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\Runoff Models\Rev2_Nov 2023\Summary_Models_20241105_rev0_jls.xlsx

A frequency analysis was performed using the time series of annual runoff rates generated from the model, producing annual runoff rates associated with a range of exceedance probabilities. Multiple distributions were tested against the historical data, including the Normal, Log Normal, Gumbel, Gamma, Pearson III, Log Pearson III, and GEV distributions, and the Gamma distribution was selected as the best statistical fit to observed data. Results of annual runoff for a range of return periods are presented in Table 4-30.

4.2.6 Baseflow Review

The calibrated rainfall-runoff model incorporates a constant baseflow value for each stream. Results of the calibration were compared against the monthly baseflow estimates calculated from the baseflow separation technique described in Section 4.2.4 and are presented in Figure 4-33.

Points on the plot represent the constant and calibrated unit baseflow estimates for each stream, while lines show the monthly results from the baseflow separation model.

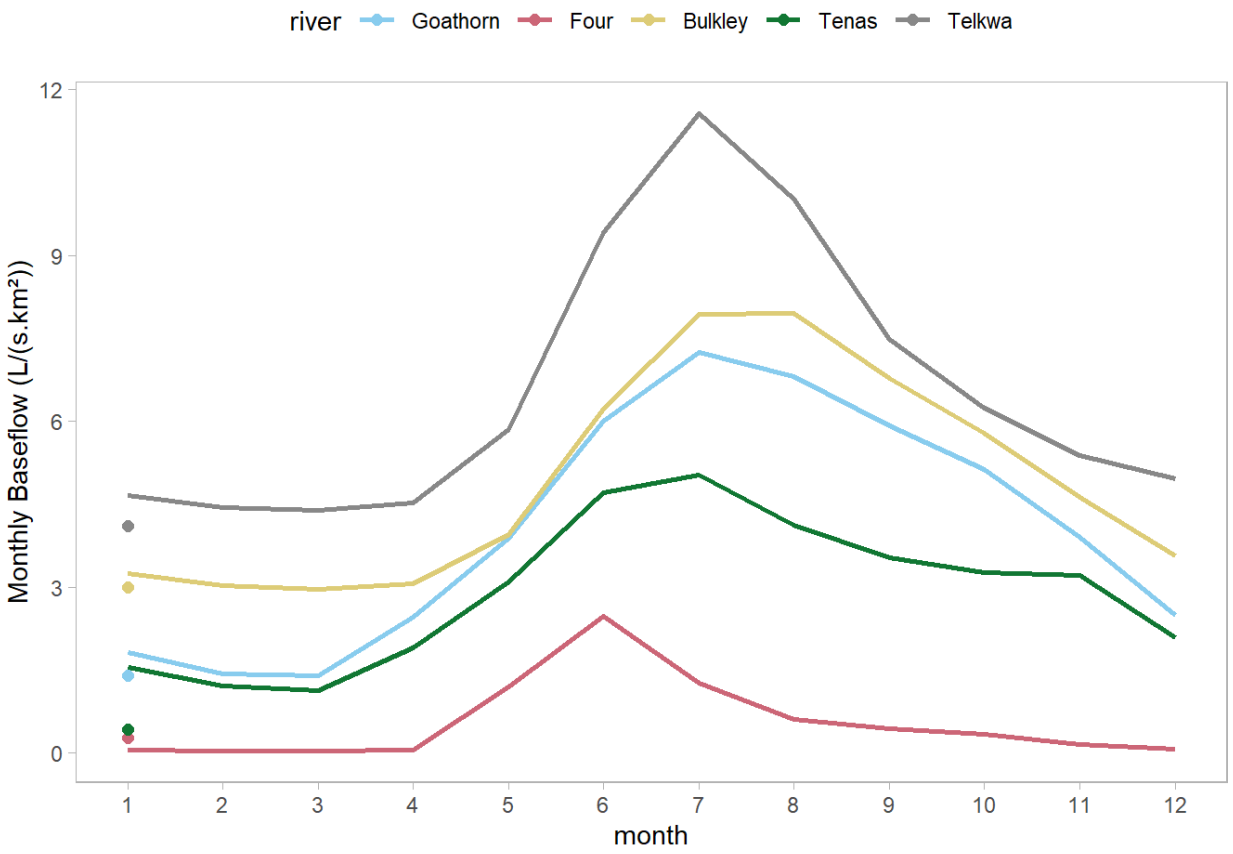

Figure 4-33: Comparison of Calibrated Unit Baseflows and Monthly Baseflow Separation Results

Source: \SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\200_Review New Climate and Streamflow Data\R_work\reports\01 - Flow Review.html

The constant calibrated baseflow estimates are representative of the winter and low flow monthly baseflow results from the baseflow separation. Based on the rainfall-runoff model used, the only time of year where the constant baseflow input is used is during winter months without rainfall or snowmelt. This is reasonable since the monthly runoff coefficients are calibrated to match flows in the open water season, and therefore account for baseflow contributions in their development.

The calibrated constant baseflow selected for Four-Hydro was compared against the available low-flow manual measurements collected since 2020 and presented in AGRA 1999, in the development of station rating curves. Measurement statistics are presented in Table 4-31 and show that the selected model baseflow for Four Creek, selected as 0.30 L/s/km^2, is approximately the minimum of winter baseflow measurements collected from Four Creek in 2020-2022.

Table 4-31: Four Creek Baseflow and Available Measurements Comparison

Type	Date	Statistic	Unit Flow [L/s/km^2]
Manual Measurement	All year	Minimum	0.18
Manual Measurement	All year	25th percentile	0.59
Manual Measurement	All year	50th percentile	1.08
Manual Measurement	All year	Average	1.71
Manual Measurement	Winter	Minimum	0.27
Manual Measurement	Winter	25th percentile	0.73
Manual Measurement	Winter	50th percentile	1.18
Manual Measurement	Winter	Average	1.94

The calibrated constant unit baseflows were used in groundwater modeling calibration to develop base case estimates of baseflow.

4.2.7 Peak Flows

A peak flow analysis was performed for Tenas Creek, Goathorn Creek, Telkwa River and Four Creek based on the synthetic records detailed in section 4.2.3. The Bulkley River peak flow analysis was based on the extended records from WSC Bulkley River at Quick 08EE004 hydrometric station. Table 4-32 presents the unit peak-flows for each identified stream.

Table 4-32: Unit Peak Flows from Extended Records [L/s/km^2]

Return Period [years]	Goathorn-Hydro (Synthetic)	Telkwa-Hydro (Synthetic)	Tenas-Hydro B (Synthetic)	Four-Hydro (Synthetic)	WSC Bulkley River at Quick 08EE004
1000	388	620	506	173	165

4.2.8 Low Flows

A low flow analysis was performed for Tenas Creek, Goathorn Creek, Telkwa River and Four Creek based on the synthetic records detailed in section 4.2.8. The Bulkley River low flow analysis was based on the extended records from WSC Bulkley River at Quick 08EE004 station. Table 4-33 presents the day low-flows for each identified stream.

Table 4-33: 7-Day Low Flows from Extended Records [L/s]

Return Period [years]	Goathorn-Hydro (Synthetic)	Tenas-Hydro B (Synthetic)	Telkwa-Hydro (Synthetic)	Four-Hydro (Synthetic)	WSC Bulkley River at Quick 08EE004

5 Climate Change

Climate change is considered one of human civilization's many challenges as it has the potential to impact current social and ecological systems. Estimating potential variation in future climate conditions to identify vulnerability, assess risk and develop adaptive management strategies is in the best interest of mine developers and operators.

The section below discusses climate change trends and effects that may impact the Project. This analysis was completed for temperature and precipitation, and incorporated into the evaporation and streamflow models discussed in Section 4.

5.1 Contextual Framework

While observed historical datasets have traditionally been used to investigate climate patterns and trends, global circulation models (GCMs, aka climate change models) are better suited to generate synthetic datasets with which to investigate the potential range of impacts of climate change into the future on a global or continental scale. GCM results can be scaled to local weather station datasets or gridded climate datasets to provide localized, site-specific projections.

The Coupled Model Intercomparison Project (CMIP) is organized under the support of the World Climate Research Program's (WCRP) working group on coupled modelling. It coordinates experiments on coupling computer-based models of the Earth's climate such as GCMs. The objective of CMIP is to better understand past, present, and future climate change arising from natural unforced variability or in response to changes in radiative forcing in a multi-model context (Eyring 2016). The CMIP is currently in its sixth phase (CMIP6) and its outcomes contribute to the most recent assessments and reports from the International Panel on Climate Change (IPCC, 2023).

CMIP6 includes the most up to date, peer-reviewed models for the simulation and projection of various aspects of climate change. The CMIP6 models include new and better representations of physical, chemical, and biological processes at higher resolution than its previous phases. This has improved the simulation of the recent mean state of most large-scale indicators of climate change and many other aspects across the climate system.

This climate change assessment was based on results from GCMs included in CMIP6 and the corresponding IPCC Sixth Assessment Report (AR6) (IPCC, 2021). The data compilation and subsequent analysis was conducted in the R Software environment.

5.2 Climate Change Methodology

Climate change scenarios were evaluated considering Shared Socioeconomic Pathways (SSP). SSPs are a set of scenarios that describe potential future developments in the absence of climate policy intervention. These pathways are used to explore the possible impacts of different socioeconomic trends on climate change and to assess the challenges associated with mitigation and adaptation strategies. Figure 5-1 shows possible combinations of SSPs with different radiative forcing levels. Four scenarios (Tier 1) are generally recommended for climate change assessments - SSP 1-2.6, SSP 2-4.5, SSP 3-7.0 and SSP 5-8.5 (O'Neill, et al., 2016)-, which span the range of radiative forcing levels and SSPs.

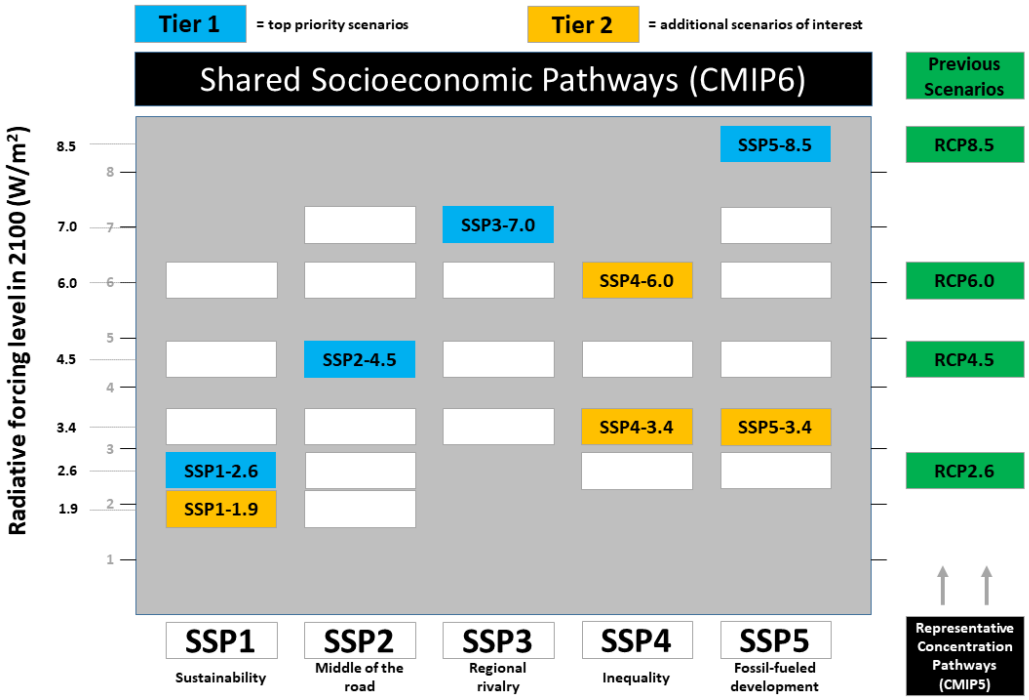

Figure 5-1: Shared Socio-economic Pathways and year 2100 radiative forcing combinations

Source: https://climate-scenarios.canada.ca/?page=cmip6-overview-notes

A short description of these scenarios is provided below.

- SSP5-8.5: With an additional radiative forcing of 8.5 W/m² by the year 2100, this scenario represents the upper boundary of the range of scenarios described in the literature. It can be understood as an update of the CMIP5 scenario RCP8.5, now combined with socioeconomic reasons.
- SSP3-7.0: With 7 W/m² by the year 2100, this scenario is in the upper-middle part of the full range of scenarios. It was newly introduced after the RCP scenarios, closing the gap between RCP6.0 and RCP8.5.
- SSP2-4.5: As an update to scenario RCP4.5, SSP245 with an additional radiative forcing of 4.5 W/m² by the year 2100 represents the medium pathway of future greenhouse gas emissions. This scenario assumes that climate protection measures are being taken.
- SSP1-2.6: This scenario with 2.6 W/m² by the year 2100 is a remake of the optimistic scenario RCP2.6 and was designed with the aim of simulating a development that is compatible with the 2°C target. This scenario, too, assumes climate protection measures being taken.

National Aeronautics and Space Administration (NASA, 2017) provides access to gridded global climate data NEX-GDDP-CMIP6 (Thrasher, et al., 2022), which comprises 26 CMIP6 models for the period of 1950 – 2100, with historical results from 1950 to 2014 and forecast results from 2015 to 2100. Data for the Tenas Project location were obtained and processed by SRK to evaluate predicted trends up to year 2100, deemed the maximum reasonable prediction range (IPCC, 2023).

Once the Global Circulation Models (GCM) are developed in a coarse spatial resolution, a bias correction procedure is required to adjust their estimates to represent local climate conditions of a specific site considering its microclimate. In this work, GCM historical and forecasted data are bias corrected with Quantile Delta Mapping (QDM) referencing the derived historical timeseries introduced in Section 4 as the observed variables. QDM is applied to the meteorological variables grouped by month – i.e., the bias correction preserves month-specific variability.

Each model under each different SSP represents one possible future climate scenario. Summarizing the models' results by the median or average may facilitate the interpretation and provide insights into agreement among models, but it may hinder extreme conditions that are usually of interest to stakeholders for risk assessment. Thus, SRK chose to show the results for four conditions that will encompass extreme cases of high and low water availability, as well as an average case that will represent the midpoint trend of the GCMs.

Projected climate change effects were evaluated relative to a defined baseline period for three consecutive 30-year forecast periods, defined as follows:

- Baseline period from 1985 to 2014 (CMIP6)
- First forecast period from 2015 to 2040 (CMIP6)
- Second forecast period from 2041 to 2070 (CMIP6)
- Third forecast period from 2071 to 2100 (CMIP6)

One model within the GCM/SSP ensamble was selected to represent each of the following four conditions for each forecast period:

- Minimum long term net water balance (precipitation - evaporation) – $min_{(P-E)}$
- Maximum long term net water balance – $max_{(P-E)}$
- Midpoint condition (median precipitation with median evaporation) – $med_P med_E$
- Lowest long term Precipitation – min_P

These conditions were selected based on the critical components of the Project, and aim to cover climate change related uncertainty during the life of the Project.

The following sections present the climate change analysis for mean annual and monthly air temperature as well as mean annual and monthly precipitation. Changes to lake evaporation and streamflow were also assessed based on the climate change forecasts.

5.3 Model Selection

For each time period, the models were assessed by comparing rates of change for precipitation and evaporation in order to identify extreme and average conditions. Figure 5.2 showcases these rates of change envelope for modelled climate outcomes from the GCM's for all scenarios. Models selected by SRK to illustrate the range of climate change outcomes are highlighted (thick circle lines). The selected models are also presented in Table 5-1.

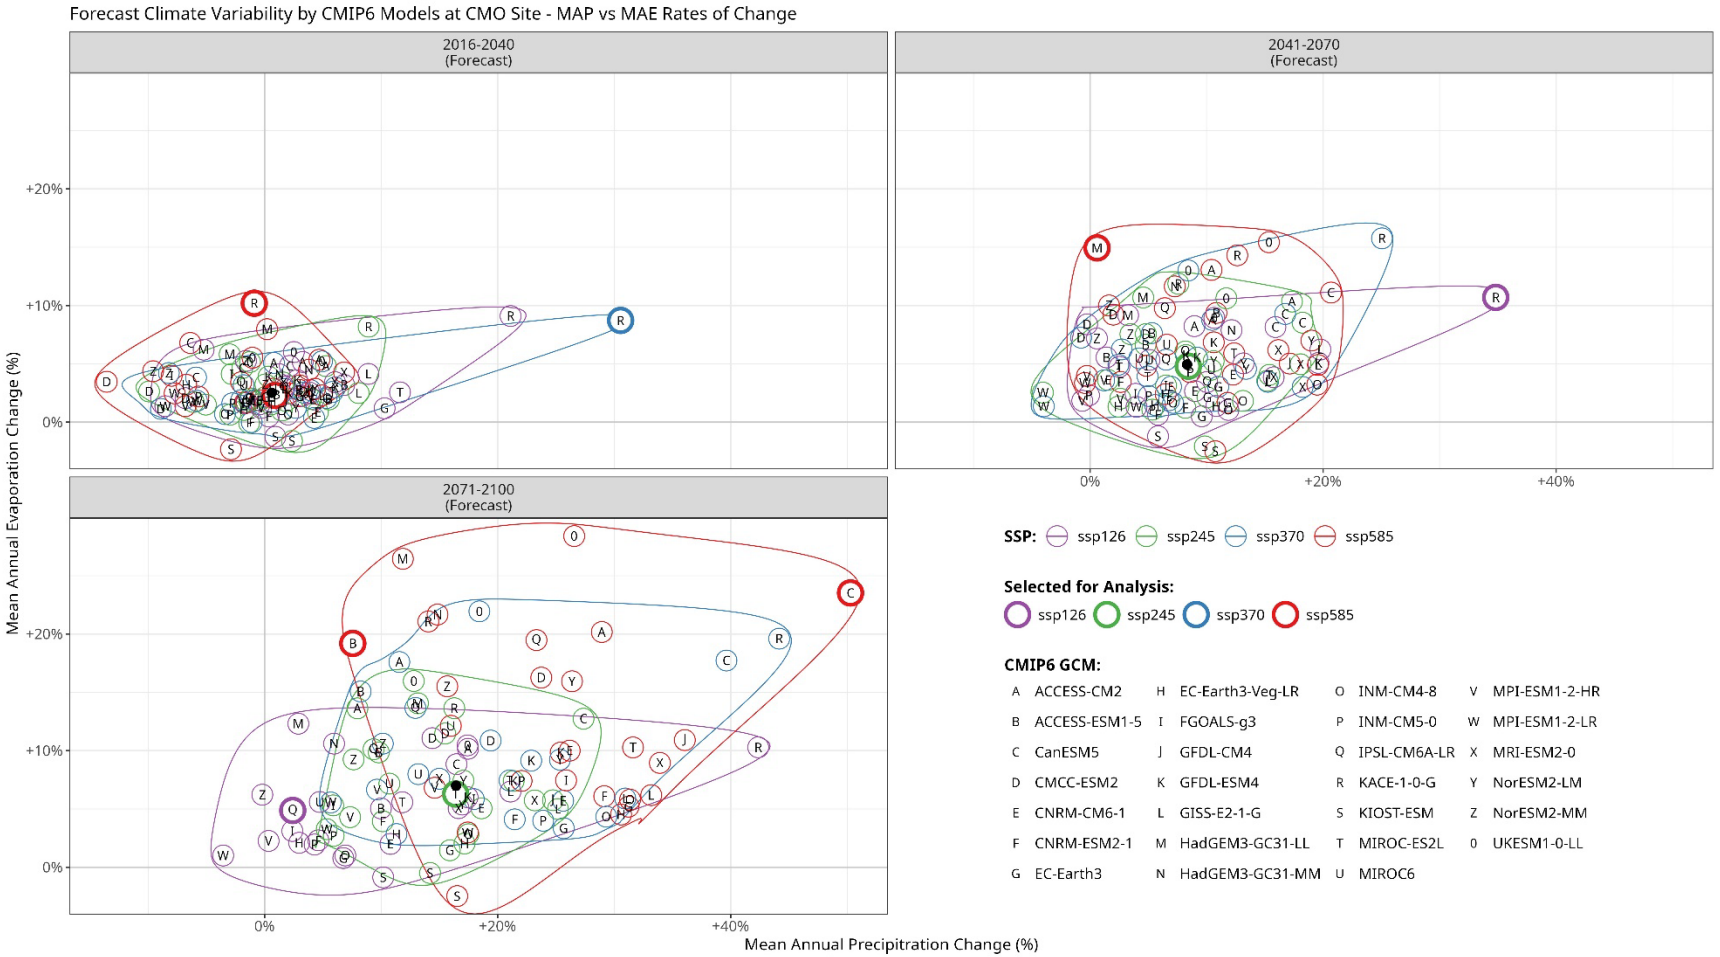

Figure 5.2: Model selection per forecast period

Source: SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\Climate Change Update\figures\cc_model_prcp_evap.tif

Table 5-1: Adopted models for each forecast period

Forecast Period	Condition	Model (SSP)
2015 – 2040	$med_P med_E$	MIROC-ES2L (SSP5-8.5)
	$max_{(P-E)}$	KACE-1-0-G (SSP3-7.0)
	$min_{(P-E)}$	KACE-1-0-G (SSP5-8.5)
	min_P	CMCC-CM2-SR5 (SSP2-4.5)
2051 – 2070	$med_P med_E$	GISS-E2-1-G(SSP2-4.5)
	$max_{(P-E)}$	KACE-1-0-G(SSP1-2.6)
	$min_{(P-E)}$	HadGEM3-GC31-LL(SSP5-8.5)
	min_P	IITM-ESM(SSP3-7.0)
2071 – 2100	$med_P med_E$	MIROC-ES2L(SSP2-4.5)
	$max_{(P-E)}$	CanESM5(SSP5-8.5)
	$min_{(P-E)}$	ACCESS-ESM1-5(SSP5-8.5)
	min_P	IPSL-CM6A-LR(SSP1-2.6)

5.4 Climate Change Effects to Temperature

5.4.1 Annual Temperature Trends

Figure 5-3 presents the mean annual air temperature (MAAT) from the Project record during the baseline period, as well as the historical CMIP6 ensemble results over the same period and the forecasted MAAT for the four different SSPs.

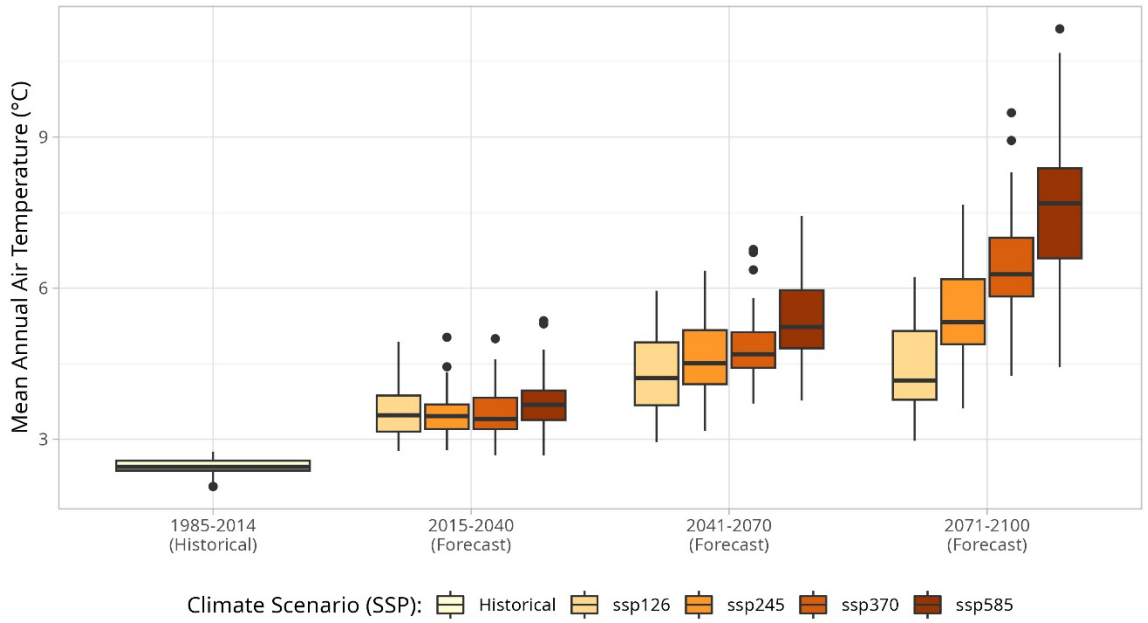

Figure 5-3: Forecast of Climate Change Effect on Mean Annual Air Temperature

Source: SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\Climate Change Update\figures\cc_periods_tavg.tiff

Table 5-2 presents the rates of change relative to the historical results for the four conditions up to year 2100 using CIMP6 data.

Table 5-2: Mean Annual Air Temperature Increase from Baseline (in °C)

Timeframe	$med_P med_E$	$max_{(P-E)}$	$min_{(P-E)}$	min_P
2015-2040	1.0	2.5	2.8	0.4
2041-2070	2.2	3.1	4.1	1.3
2071-2100	2.3	8.2	5.7	1.7

Source: compiled in text from R code SRK Consulting\NA CAPR002055 Telkwa Project General EA Support - Internal\Climate Change Update\report\climate_change_rev0.html

Based on the selected scenarios, the mean annual temperature for the Project is expected to increase by 2°C to 8°C by year 2100.

5.4.2 Monthly Temperature Rates of Change

Monthly impacts to temperature as a result of climate change were evaluated using the same methodology as described above. The projections are shown below in Table 5-3 for the four conditions and three time periods.

Table 5-3: Monthly Average Temperature Increase from Baseline (in °C)

Period	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Ann

5.5.3 Extreme Precipitation with Climate Change

Rates of change for extreme precipitation under climate change conditions were estimated for each time period. Rates of change are expressed by the ratio between future and historical precipitation for a set of return periods. For this, the Generalized Extreme Value (GEV) distribution was fitted using L-moments method (Hosking, 2023) to bias corrected historical and future annual maximum daily rainfall to represent extreme precipitation frequency under historical and projected future conditions. The rates of change are provided in Table 5-6 in terms of percentiles. Depth-Duration-Frequency can be obtained by multiplying the historical quantiles (Table 4-8) by the rates of change presented in this section.

Table 5-6: Rates of change for Project Depth-Duration-Frequency Curves with Climate Change

Percentile	Return Period							
	2	5	10	25	50	100	200	1000
Period 2015 – 2040								
10	−9%	−12%	−12%	−15%	−18%	−21%	−24%	−30%
25	−4%	−2%	−3%	−6%	−7%	−10%	−12%	−15%

5.6 Climate Change Effects to Lake Evaporation

Changes to lake evaporation were assessed by updating the Morton CRWE methodology described in Section 2.3.7 with the temperature changes obtained for RCP 4.5 and presented in Table 5-6. The maximum temperature, minimum temperature and dew temperature Project time series were updated using the same net increase rates. Note that the model did not apply a climate change adjustment to solar radiation. Table 5-7 presents the monthly and annual rates of change relative to the baseline lake evaporation.

Table 5-7: Monthly Lake Evaporation Percentual Variation from Baseline

Notes:
1. Not able to calculate lake evaporation with the selected model. Replaced by the model with second lowest precipitation – CMCC-ESM2 (SSP5-8.5)
2. Not able to calculate lake evaporation with the selected model. Replaced by the model with second lowest precipitation – ACCESS-ESM1-5 (SSP126)

5.7 Climate Change Effects to Streamflow

The calibrated rainfall-runoff model was updated to include the projected rates of change to temperature and precipitation. Calibrated monthly runoff coefficients and baseflow values were incorporated for each major stream. Monthly flows from historic climate were compared against monthly flows projected in 2100 based on the monthly climate change variability.

The runoff model was simulated for 100 realizations under historic conditions and projected climate change conditions (year 2100). The 50th percentile (median), 10th percentile (low flow) and 90th percentile (high flow) statistics were extracted from the realization record, and are compared in each creek for historic conditions versus 2100 climate change conditions.

Historic monthly streamflow for each percentile and both historic and climate change conditions are presented in Figure 5-5 for Goathorn Creek, Figure 5-6 for Tenas Creek, Figure 5-7 for Telkwa River, Figure 5-8 for Bulkley River and Figure 5-9 for Four Creek, where the solid lines represent the median results and dashed lines the 10th and 90th percentiles.

The general tendency when comparing historic and climate change monthly streamflow is an overall increase in flow magnitude and a shift to an earlier spring freshet. These observations coincide with the climate change projections in Table 5-5, showing even a 2% in annual precipitation by 2100, and a 23% increase in precipitation in May under the model with lowest precipitation increase.

Note that the runoff model relies on a constant unit baseflow value for each river, which was not adjusted for climate change in these predictions. Precipitation is anticipated to decrease during the drier summer months (namely July), which, in combination with the higher evaporation rates in Table 5-7, would be expected to decrease streamflow during the low-flow summer period.

In addition, the changes to seasonality and snowmelt timing would also affect the runoff coefficients. The calibrated runoff coefficients were based on the historical flow regime, which coincides with a spring freshet in May. The monthly runoff coefficients could also be affected by climate change and are an additional limitation of this evaluation approach.

5.7.1 Peak Flow Trends

A trend analysis was carried out by SRK to identify trends and significance of trends for the peak flows from historical records. Ordinary least squares method, and quantile regression method were employed for statistical evaluation of the data. The non-parametric Mann-Kendall (MK) (1945) and Theil-Sen methods, the Prewhitening MK (Zhang 2000) method, and the Prewhitening MK (Yue et al. 2002) method were used for trend analysis. Where a trend was observed (upward or downward), its significance was evaluated. Trends with a significance greater than 95% are accepted as significant.

Goathorn Creek Peak Flow Historical Trend Analysis

Figure 5-10 represents yearly peak flows at the Goathorn WSC station from the extended timeseries, and its linear approximation equation obtained with the ordinary least squares method. Table 5-8 summarizes the results of the Goathorn peak flow trend statistical significance Mann-Kendall tests. No significant trend is observed for all three tests.

In all streams evaluated, no significant change in peak flow magnitude has been observed historically. This is not to say that a change in peak flows may not occur with projected climate change. Variations with respect to snowmelt timing and rainfall depth may result in higher peaks in the future, however the effects of a thinner snowpack should also be considered. Peak flow models for the purpose of engineering design should incorporate both snowmelt events and climate change depth-duration-frequency rainfall tables presented in Table 5-6.

6 Conclusions and Limitations

Regional analyses coupled with a compilation of Project-specific meteorological and hydrometric datasets were used to develop Project specific hydrometeorological baseline parameters, including long-term temperature and precipitation records. Climate change analysis was updated with CMIP6 data. Climate change effects on temperature, precipitation, evaporation and streamflow are presented as monthly and annual rates of change for three future periods. Results from this study may be used to further advance Project designs and update EA modeling, including the water and load balance model, groundwater model, and design of water management infrastructure.

Available Four Hydro data for 2020, 2021 and 2022 were analysed, along with data collected as part of baseline monitoring in 1997 and 1998. Due to the limited period of record, there is still significant uncertainty regarding Four Creek hydrology. Ongoing monitoring and validation of presented hydrologic indices is required.

The calibrated rainfall runoff model established to support the water and load balance model and runoff estimates for the hydrometric stations underestimates flows in Tenas Creek. This model should be revisited once more flow data is available at Tenas Hydro. However for the purpose of the EA, an underestimated runoff result is more conservative in terms of dilution capacity. Review of the Four-Hydro regressions with Goathorn Creek (08EE008) and calibration model should be performed after an additional year of monitoring data become available.

It is strongly suggested that this study be revisited and that the model be recalibrated when longer Project data records are available from the meteorological station as well as the hydrometric stations, and when all WSC flow data are published. The correlations between meteorological parameters measured at the Tenas Deposit Station and the regional stations should be improved by assessing a longer period of Project record from the Tenas Deposit Station. An initial analysis of the precipitation record showed that recent years were drier than average, which may create bias in the extended Project precipitation record. Complete water years (from October to September of the following year) are critical in any assessment of the hydrological regime and longer flow data series will improve streamflow regressions and provde a robust calibration dataset.

Attention: Mr. Allan Flemming

Dear Mr. Flemming:

RE: TELKWA COAL PROJECT 1999 BASELINE SURFACE FLOW AND WATER QUALITY FINAL DATA REPORT

AGRA Earth & Environmental Limited (AGRA) is pleased to submit two copies of the *Telkwa Coal Project 1999 Baseline Surface Flow and Water Quality Final Data Report*. The report presents the results of the 1999 field monitoring program conducted by AGRA for Luscar Ltd. on the proposed Telkwa Coal Project.

AGRA understands that the recent state of the coal industry has put the proposed Telkwa Coal Project on hold. AGRA looks forward to working with Luscar Ltd. on the proposed Telkwa Coal Project when the decision to proceed with the project is made. Should you have any questions or comments regarding this report, or require any support on this, or other projects, please do not hesitate to contact the undersigned at (250) 847-8783.

Respectfully submitted,

AGRA Earth & Environmental Limited

Dear Mr. Flemming:

RE: TELKWA COAL PROJECT 1999 BASELINE DATA REPORT

1.0 INTRODUCTION

AGRA Earth & Environmental Limited is pleased to present the 1999 Baseline Surface Water Flow and Water Quality Monitoring Report for the Telkwa Coal Project (TCP). The TCP is a proposed open pit coal mine located near Telkwa, B.C. and owned by Luscar Inc. (Luscar). The location of the mine is illustrated on Figure 1. This report contains the data collected during the 1999 baseline monitoring program and updates the rating curves for sites where discharge measurements were conducted.

2.0 SCHEDULE OF 1999 SITE VISITS

The schedule of site visits for the 1999 field monitoring program is contained in the March 3, 1999 AGRA proposal to conduct the TCP baseline monitoring. A copy of the AGRA proposal is contained in Appendix A for reference. The dates of actual site visits and a listing of the work conducted during the site visits is contained in Table 1.

TABLE 1: 1999 MONITORING SITE VISITS

Week of:	Feb 1	Aug 1	Sept 19	Nov 14
Telkwa River	WQ		WQ	
Upper Tenas Creek	No site access		SM, WQ, Q	S
Lower Tenas Creek	WQ, Q	S	SM, WQ, Q	S
Bulkley River	WQ		WQ	
Hubert Creek	WQ, S	S	WQ, S	S
Four Creek	WQ	S	WQ, Q	S
Upper Goathorn Creek	WQ, Q		SM, WQ, Q	S
Lower Goathorn Creek	WQ		WQ	

Q = Discharge and stage measurements conducted
S = Stage measurements conducted
WQ = Water quality sampling conducted
SM = Site Maintenance Visit

The purpose of the August field trips was to collect peak flow information from the crest gauges at each site.

3.0 SURFACE WATER MONITORING RESULTS

This section contains a summary of the five sites where surface water monitoring was conducted during the 1999 field season. Summary field data for the site visits is contained in Appendix B.

3.1 LOWER TENAS CREEK SITE

The Lower Tenas Creek site was visited four times as part of the 1999 monitoring program. The station was operated as a manual sampling with no installation of the automated equipment used in previous years.

The two low flow discharge measurements conducted during February and September yielded discharges of 0.041 m^3/s and 0.163 m^3/s respectively. These discharge measurements have been added to the rating curve and a revised rating curve for this site is shown in Figure 2.

An initial crest gauge installed in late 1998 at the site was replaced during the 1999 sampling season. Level surveys conducted at the site during the 1999 field season did not show significant shift of the benchmarks or the staff gauge. There was evidence of sand deposition noted near the gauge during the November 1999 field visit.

3.2 UPPER TENAS CREEK SITE

The upper Tenas Creek was visited twice during the 1999 monitoring program. There was no site access during the February 1999 field trip. As the crest gauge for this site was not checked and reset during February, this site was not visited during the August field trip.

The crest gauge was checked during September and the maximum stage was observed to be 0.70 m. This value would translate to a discharge of 8.43 m^3/s and is expected to be due to the spring freshet which consistently produces greater discharges than the fall peak flows. The low flow measurement from September 20th was 0.134 m^3/s. An updated rating curve for this site is shown in Figure 3.

The September field visit to this site showed that the braces for the staff gauge had snapped but that the staff gauge did not appear to have shifted (based on a review of previous site photographs). Braces at the site were replaced and a third benchmark was added on the right bank side of the stream. Levelling checks showed that there was no significant shift of the benchmarks or the staff gauge during 1999. The breakage of the braces resulted in slight downstream leaning of the staff gauge mounting but this was corrected during the site maintenance visit.

3.3 UPPER GOATHORN CREEK SITE

The Upper Goathorn Creek site was visited four times during the 1999 monitoring program. The station was monitored as a manual station with a staff gauge and crest gauge.

The two low flow discharge measurements conducted during February and September yielded discharges of 0.097 m^3/s and 0.337 m^3/s respectively. These discharge measurements have been added to the rating curve and a revised rating curve for this site is shown in Figure 4.

Maintenance of the gauge equipment was conducted during the September visit. The bracing for the staff gauge was reinforced and the staff gauge was lowered by a distance of 0.19 m. A second staff gauge was added to the top of the first staff gauge to allow for visual measurement of peak flow levels during the freshet period. The level check of benchmarks showed that there were no changes in the elevations of the benchmarks. The staff gauge did not show any significant shift during the 1999 season.

3.4 FOUR CREEK SITES

Two sampling locations were operated on Four Creek during the 1999 field season. The low flow discharge measurements were made at the lowest culvert crossing of Four Creek on the 120 Road. Other stage measurements and water quality sampling were conducted at the original stream flow sampling site located approximately 1,800 m upstream of the culvert crossing on Four Creek.

Discharges for the low flow periods were determined by calculation of the discharge through the culvert based on the known inlet water levels and the culvert characteristics. The February low flow measurement revealed that there was only a small quantity of baseflow (< 1L/min) during the sampling trip. The culvert was almost completely iced up. The September low flow discharge for the culvert was calculated to be 0.077 m^3/s.

3.5 HUBERT CREEK SITE

The Hubert Creek site was visited four times during the 1999 monitoring program. Readings for the staff gauge are available from two of the site visits. Visits conducted during September and November did not yield useful data on flow levels due to numerous partial blockages of the culvert inlet by debris.

The crest gauge at the site indicated that there was a recorded stage greater than 1.23 m during the spring 1999 freshet period. This high stage is believed to be partially due to beaver debris blockage of the inlet of the Hubert Creek culvert.

4.0 WATER QUALITY MONITORING RESULTS

In 1999, baseline water chemistry was sampled during the two low flow periods at ten sites in the proposed Telkwa Coal Project area. The data for the February 1999 water quality monitoring was forwarded directly to Luscar as previously arranged. The laboratory results for

the September water quality trip are included in Appendix C of this report. No analysis of the testing data, other than to identify specific stations where the BC Water Quality Criteria (Nagpal, 1995) were exceeded. A summary of metals and stations where exceedances occurred are summarized in Table 2. Due to operator error, no replicate sampling was conducted during the September water quality monitoring trip.

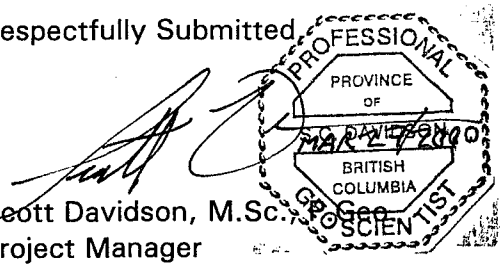

TABLE 2: B.C. WATER QUALITY CRITERIA EXCEEDANCE INFORMATION FOR THE SEPTEMBER 20, 1999 SAMPLING TRIP

METAL	B.C. WATER QUALITY CRITERIA	STATIONS WITH TOTAL METALS CONCENTRATIONS GREATER THAN THE B.C. CRITERIA	STATIONS WITH TOTAL METALS CONCENTRATIONS EQUAL TO THE B.C. CRITERIA
Cr	2.0 ug/L	Telkwa River (2.5)	Upper Goathorn Creek, Lower Goathorn Creek, Bulkley River, Hubert Creek, Lower Tenas, Four Creek
Cu	2.0 ug/L	Telkwa River (2.4)	
Fe	0.3 mg/L	Telkwa River (0.8), Hubert Creek (1.03), Bulkley River (0.33)	
Zn	3.0 ug/L	Telkwa River (3.5)	

5.0 CLOSURE

AGRA Earth Environmental Limited is pleased to present this 1999 data summary to Luscar Ltd. AGRA looks forward to continuing to work with Luscar on the Telkwa Coal project over the 2000 season. Should you have any questions concerning this project please do not hesitate to contact the undersigned at (250) 847-8783.

Dear Mr. Flemming:

RE: TELKWA COAL PROJECT 1999 BASELINE DATA REPORT

1.0 INTRODUCTION

AGRA Earth & Environmental Limited is pleased to present this proposal to conduct the 1999 Baseline Surface Water Flow and Water Quality Monitoring Report for the Telkwa Coal Project (TCP). The TCP is a proposed open pit coal mine located near Telkwa, B.C. and owned by Luscar Inc. (Luscar). This report contains the data collected during the 1999 baseline monitoring program and updates the rating curves for sites where discharge measurements were conducted.

2.0 SCHEDULE

SURFACE WATER MONITORING

AEE is pleased to present this revised budget for the 1999 baseline water flow and water quality program for the proposed Telkwa Coal Project. It is the understanding of AEE that during 1999 Luscar should be submitting the Final Project Report to the B.C. Environmental Assessment Office. Following certification of the project, it is the understanding of AEE that the entire surface water and water quality program may need to be revised to meet the construction plan for the mine.

2.0 WORK PROGRAM AND BUDGET

The work program proposed for 1999 is as follows:

Surface Water Flow

- Concentration of the base program on the winter and summer low flow periods.
- Monitoring of low flows on Four Creek, Hubert Creek, Tenas Creek, Upper Goathorn Creek and Lower Goathorn Creek. No monitoring will be conducted on Helps Creek, Telkwa River, and the Bulkley River. Low flow monitoring will result in two site visits. To reduce cost to Luscar, AEE has scheduled the summer low flow period measurement trip to

coincide with site visit #3 described below.

- Monitoring of peak flows at the streams using crest gauges already installed at all of the existing sites. To conduct this portion of the required work, AEE will conduct a total of four sites visits planned as follows:

1. Pre-freshet to set up crest and staff gauges and survey to local bench marks (April),
2. Post freshet to record peak flow during period and survey to local bench marks (June),
3. Pre fall high flow period to re-survey benchmarks and survey to local bench marks (late August to early September),
4. Post fall high flow to record peak flow and survey to local bench marks (November).

Water Quality

- Sampling of baseline parameters for the two low flow periods only.

Data Analysis

AEE proposes to conduct data analysis and reporting for the 1999 sampling program following each monitoring trip. A data analysis period has been allowed following each of the five surface flow site visits (one low flow and four peak flow visits) described above. The information reports from each trip will assist Luscar in public meetings by providing the most up to date information on the project.

Project Management

Project management involves dealing with items such as cost control, client liaison, and interfacing with other consultants working for Luscar on the proposed Telkwa Coal Mine. For the 1999 sampling program, AEE proposes to conduct project management on a cost plus basis. The totals for this item in the attached Table 1 represent estimates of the total budget required for project management. AEE will make every effort to ensure that it conducts stringent cost control on the project management for Luscar. Project management for the 1999 program will be conducted by Mr. Scott Davidson, M.Sc., P.Geo. of the Smithers office. Mr. Gary Beckstead, M.Sc., P.Eng. and Mr. Dennis Trotter will provide technical input and review to the project as required.

3.0 CLOSURE

We thank you for the opportunity to provide engineering and environmental services to this project and look forward to continuing to work with Luscar on the proposed Telkwa Coal Mine during 1999. If you have any questions or require further information concerning this project, please call Scott Davidson at (250) 847-8783 or Gary Beckstead at (403)235-8118.

Yours sincerely,

AGRA Earth & Environmental Limited

Dear Mr. Flemming:

RE: TELKWA COAL PROJECT 1999 BASELINE DATA REPORT

1.0 INTRODUCTION

AGRA Earth & Environmental Limited is pleased to present the 1999 Baseline Surface Water Flow and Water Quality Monitoring Report for the Telkwa Coal Project (TCP). The TCP is a proposed open pit coal mine located near Telkwa, B.C. and owned by Luscar Inc. (Luscar). The location of the mine is illustrated on Figure 1. This report contains the data collected during the 1999 baseline monitoring program and updates the rating curves for sites where discharge measurements were conducted.

2.0 SCHEDULE OF 1999 SITE VISITS

The schedule of site visits for the 1999 field monitoring program is contained in the March 3, 1999 AGRA proposal to conduct the TCP baseline monitoring. A copy of the AGRA proposal is contained in Appendix A for reference. The dates of actual site visits and a listing of the work conducted during the site visits is contained in Table 1. The discharge measurement focus was on the low flow periods.

TABLE 1
1999 Monitoring Site Visits

Week of:	Feb 1	Aug 1	Sept 19	Nov 14
Telkwa River	WQ		WQ	
Upper Tenas Creek	No site access		SM, WQ, Q	S
Lower Tenas Creek	WQ, Q	S	SM, WQ, Q	S
Bulkley River	WQ		WQ	
Hubert Creek	WQ, S	S	WQ, S	S
Four Creek	WQ	S	WQ, Q	S
Upper Goathorn Creek	WQ, Q		SM, WQ, Q	S
Lower Goathorn Creek	WQ		WQ	

Q = Discharge and stage measurements conducted
S = Stage measurements conducted
WQ = Water quality sampling conducted
SM = Site Maintenance Visit

The purpose of the August field trips was to collect peak flow information from the crest gauges at each site and to survey the equipment and benchmarks at each site for the low flow period.

3.0 SURFACE WATER MONITORING RESULTS

This section contains a summary of the five sites where surface water monitoring was conducted during the 1999 field season. Summary field data for the site visits is contained in Appendix B.

3.1 LOWER TENAS CREEK SITE

The lower Tenas Creek site was visited four times as part of the 1999 monitoring program. The station was operated as a manual sampling with no installation of the automated equipment used in previous years.

The two low flow discharge measurements conducted during February and September yielded discharges of 0.041 m^3/s and 0.163 m^3/s respectively. These discharge measurements have been added to the rating curve and a revised rating curve for this site is shown in Figure 2.

An initial crest gauge installed in late 1998 at the site was replaced during the 1999 sampling season. Level surveys conducted at the site during the 1999 field season did not show significant shift of the benchmarks or the staff gauge. There was evidence of sand deposition noted near the gauge during the November 1999 field visit.

3.2 UPPER TENAS CREEK SITE

The upper Tenas Creek was visited twice during the 1999 monitoring program. There was no site access during the February 1999 field trip. As the crest gauge for this site was not checked and reset during February, this site was not visited during the August field trip.

The crest gauge was checked during September and the maximum stage was observed to be 0.70 m. This value would translate to a discharge of 8.43 m^3/s and is expected to be due to the spring freshet which consistently produces greater discharges than the fall peak flows. The low flow measurement from September 20th was 0.134 m^3/s. An updated rating curve for this site is shown in Figure 3. The two 1999 data points plot above the current stage-discharge relation. AGRA proposes that one high flow measurement be conducted at this site during the 2000 field season to determine whether the rating curve should be shifted upwards.

The September field visit to this site showed that the braces for the staff gauge had snapped but that the staff gauge did not appear to have shifted (based on a review of previous site photographs). Braces at the site were replaced and a third benchmark was added on the right bank side of the stream. Levelling checks showed that there was no significant shift of the benchmarks or the staff gauge during 1999. The breakage of the braces resulted in slight downstream leaning of the staff gauge mounting but this was corrected during the site

maintenance visit.

3.3 UPPER GOATHORN CREEK SITE

The upper Goathorn Creek site was visited four times during the 1999 monitoring program. The station was monitored as a manual station with a staff gauge and crest gauge.

The two low flow discharge measurements conducted during February and September yielded discharges of 0.097 m^3/s and 0.337 m^3/s respectively. These discharge measurements have been added to the rating curve and a revised rating curve for this site is shown in Figure 4.

Maintenance of the gauge equipment was conducted during the September visit . The bracing for the staff gauge was reinforced and the staff gauge was lowered by a distance of 0.19 m. A second staff gauge was added to the top of the first staff gauge to allow for visual measurement of peak flow levels during the freshet period. The level check of benchmarks showed that there were no changes in the elevations of the benchmarks. The staff gauge did not show any significant shift during the 1999 season.

problem with chart

3.4 FOUR CREEK SITES

Two sampling locations were operated on Four Creek during the 1999 field season. The low flow discharge measurements were made at the lowest road culvert crossing of Four Creek. Other stage measurements and water quality sampling were conducted at the original stream flow sampling site located approximately 1,800 m upstream of the culvert crossing on Four Creek.

Discharges for the low flow periods were determined by calculation of the discharge through the culvert based on the known inlet water levels and the culvert characteristics. The February low flow measurement revealed that there was only a small quantity of baseflow (< 1L/min) during the sampling trip. The culvert was almost completely iced up. The September low flow discharge for the culvert was calculated to be 0.077 m^3/s.

3.5 HUBERT CREEK SITE

The Hubert Creek site was visited four times during the 1999 monitoring program. Readings for the staff gauge are available from two of the site visits. Visits conducted during September and November did not yield useful data on flow levels due to numerous partial blockages of the culvert inlet by debris.

The crest gauge at the site indicated that there was a recorded stage greater than 1.23 m during the spring 1999 freshet period. This high stage is believed to be partially due to beaver debris blockage of the inlet of the Hubert Creek culvert.

4.0 WATER QUALITY MONITORING RESULTS

In 1999, baseline water chemistry was sampled during the two low flow periods at ten sites in the proposed Telkwa Coal Project area. The data for the February 1999 water quality monitoring was forwarded directly to Luscar as previously arranged. The laboratory results for the September water quality trip are included in Appendix C of this report. No analysis of the testing data, other than to identify specific stations where the BC Water Quality Criteria (Nagpal, 1995) were exceeded. A summary of metals and stations where exceedances occurred are summarized in Table 2. Due to operator error during the September 1999 water quality field trip, triplicate sampling was not conducted. A blank sample obtained from Chemex did not have any exceedances.

77
↖ QA/QC not done properly

TABLE 2: B.C. WATER QUALITY CRITERIA EXCEEDANCE INFORMATION FOR THE SEPTEMBER 20, 1999 SAMPLING TRIP

METAL	B.C. WATER QUALITY CRITERIA	STATIONS WITH TOTAL METALS CONCENTRATIONS GREATER THAN THE B.C. CRITERIA	STATIONS WITH TOTAL METALS CONCENTRATIONS EQUAL TO THE B.C. CRITERIA
Cr	2.0 ug/L	Telkwa River (2.5)	Upper Goathorn Creek, Lower Goathorn Creek, Bulkley River, Hubert Creek, Lower Tenas, Four Creek
Cu	2.0 ug/L	Telkwa River (2.4)	
Fe	0.3 mg/L	Telkwa River (0.8), Hubert Creek (1.03), Bulkley River (0.33)	
Zn	3.0 ug/L	Telkwa River (3.5)	

5.0 CLOSURE

AGRA Earth Environmental Limited is pleased to present this 1999 data summary to Luscar Ltd. AGRA looks forward to continuing to work with Luscar on the Telkwa Coal project over the 2000 season. Should you have any questions concerning this project please do not hesitate to contact the undersigned at (250) 847-8783.

RE: 1999 DATA REPORT UPDATE

Dear Mr. Flemming,

AGRA Earth & Environmental Limited (AGRA) is pleased to present LuscarLtd. (Luscar) with this report containing data collected as part of the 1999 Telkwa Coal Surface Water and Water Quality Baseline Monitoring Program. The data presented in this report includes low flow data from February 1999 and the results of the site visits conducted during April and May to re-establish the crest gauges at selected sites.

LOW FLOW MONITORING TRIP

Low flow monitoring was conducted at sites on February 16th and 17th, 1999. During this trip water quality sampling was also completed; the data was directly forwarded from Chemex Labs to Luscar. The list of sites and the sampling completed is presented in Table 1.

Table 1. Low Flow Monitoring Trip Summary

SITE	FLOW CONDITIONS	WATER QUALITY SAMPLING
Telkwa River	Water level was 45 cm below the level of the main staff gauge located on the old bridge pilings.	Samples for total metals, dissolved metals and general nutrient analysis were collected.
Lower Goathorn Creek	There was some flow in the creek below approximately 30 cm of ice.	Samples for total metals, dissolved metals and general nutrient analysis were collected.
Four Creek	No evidence of flow at the lower culvert crossing.	No samples collected.
Upper Goathorn Creek	Water level was 0.1 m below the staff gauge. Discharge was measured to be 0.097 m^3/s.	Samples for total metals, dissolved metals and general nutrient analysis were collected.
Lower Tenas Creek	Staff gauge reading 0.337 m. Discharge was measured to be 0.041 m^3/s.	Samples for total metals, dissolved metals and general nutrient analysis were collected.
Hubert Creek	Staff gauge iced up; Unable to estimate water level. Discharge estimated from outlet velocity and depth to be 0.024 m^3/s.	Samples for total metals, dissolved metals and general nutrient analysis were collected.

RE-ESTABLISHMENT OF CREST GAUGES AND BENCHMARKS

The monitoring program was revised to meet Luscar's request to monitor peak flows at the study streams using only crest gauges. The crest gauges were visited at accessible sites to add cork and to check the relative elevations of staff gauges and crest gauges to site benchmarks. Table 2 contains a summary of the work completed in re-establishing the monitoring gauges.

As a result of weather conditions during April and May, the re-establishment of crest gauges required that multiple field trips be made. The two upper sites on Goathorn Creek and Tenas Creek were not accessable during May due to snow and road conditions. Therefore, AGRA did not re-establish these upper two sites, but chose instead to collect peak flow information from the lower sites on these streams. This was deemed to be the most effective use of available resources and budget given ground conditions. Peak flow levels will be determined during a field trip to be made to sites during July 1999. No crest stage readings for the Upper Goathorn and Upper Tenas sites until the july visit.

Table 2. Site Re-establishment for Peak Flow Determination

SITE	DATE VISITED	WORK COMPLETED
Telkwa River	April 14th, 1999	Water level was 45 cm below the level of the staff crest gauges at the site.
Hubert Creek	April 14th, 1999	Cork added to the crest gauge at the site. Staff gauges and benchmarks leveled for determining offsets.
Tailings Pond	April 16th, 1999	Cork added to the crest gauge at the site. Weir face, staff gauge and benchmarks leveled for determining offsets.
Four Creek	May 12th, 1999	Cork added to the crest gauge at the original site. Staff gauge and benchmarks leveled for determining offsets.
Lower Tenas Creek	May 12th, 1999	Cork added to the crest gauge at the site. Staff gauge and benchmarks leveled for determining offsets.
Lower Goathorn Creek	No work conducted at the site maintained by the WSC .	
Upper Tenas Creek	(May 12th, 1999)	No access to site because of snow and road conditions.
Upper Goathorn Creek	(May 12th, 1999)	No access to site because of snow and road conditions.

AGRA Earth & Environmental Limited is pleased to present this summary of data collection and work completed to date on the Telkwa Coal Project. Digital copies of the collected data will be forwarded to Luscar. Should you require any further information on this project please do not hesitate to contact the undersigned at (250) 847-8783.

Dear Mr. Flemming:

Re: Telkwa Coal Mine
Revised 1999 Budget

1.0 SURFACE WATER MONITORING

AEE is pleased to present this revised budget for the 1999 baseline water flow and water quality program for the proposed Telkwa Coal Project. It is the understanding of AEE that during 1999 Luscar should be submitting the Final Project Report to the B.C. Environmental Assessment Office. Following certification of the project, it is the understanding of AEE that the entire surface water and water quality program may need to be revised to meet the construction plan for the mine.

2.0 WORK PROGRAM AND BUDGET

The work program proposed for 1999 is as follows:

<u>Surface Water Flow</u>

- Concentration of the base program on the winter and summer low flow periods.
- Monitoring of low flows on Four Creek, Hubert Creek, Tenas Creek, Upper Goathorn Creek and Lower Goathorn Creek. No monitoring will be conducted on Helps Creek, Telkwa River, and the Bulkley River. Low flow monitoring will result in two site visits. To reduce cost to Luscar, AEE has scheduled the summer low flow period measurement trip to coincide with site visit #3 described below.
- Monitoring of peak flows at the streams using crest gauges already installed at all of the existing sites. To conduct this portion of the required work, AEE will conduct a total of four sites visits planned as follows:

1. Pre-freshet to set up crest and staff gauges and survey to local bench marks (April),
2. Post freshet to record peak flow during period and survey to local bench marks (June),
3. Pre fall high flow period to re-survey benchmarks and survey to local bench marks (late August to early September),

4. Post fall high flow to record peak flow and survey to local bench marks (November).

Water Quality

- Sampling of baseline parameters for the two low flow periods only.

Data Analysis

AEE proposes to conduct data analysis and reporting for the 1999 sampling program following each monitoring trip. A data analysis period has been allowed following each of the five surface flow site visits (one low flow and four peak flow visits) described above. The information reports from each trip will assist Luscar in public meetings by providing the most up to date information on the project.

Project Management

Project management involves dealing with items such as cost control, client liaison, and interfacing with other consultants working for Luscar on the proposed Telkwa Coal Mine. For the 1999 sampling program, AEE proposes to conduct project management on a cost plus basis. The totals for this item in the attached Table 1 represent estimates of the total budget required for project management. AEE will make every effort to ensure that it conducts stringent cost control on the project management for Luscar. Project management for the 1999 program will be conducted by Mr. Scott Davidson, M.Sc., P.Geo. of the Smithers office. Mr. Gary Beckstead, M.Sc., P.Eng. and Mr. Dennis Trotter will provide technical input and review to the project as required.

3.0 CLOSURE

We thank you for the opportunity to provide engineering and environmental services to this project and look forward to continuing to work with Luscar on the proposed Telkwa Coal Mine during 1999. If you have any questions or require further information concerning this project, please call Scott Davidson at (250) 847-8783 or Gary Beckstead at (403)235-8118.

Yours sincerely,

AGRA Earth & Environmental Limited

Dear Mr. Flemming:

Re: Telkwa Coal Mine
Revised 1999 Budget

1.0 SURFACE WATER MONITORING

As per the January 26th, 1999 discussion between Gary Beckstead of AGRA Earth & Environmental Limited (AEE) and Allan Flemming of Luscar Ltd. (Luscar), AEE is pleased to present this revised budget for the 1999 baseline water flow and water quality program for the proposed Telkwa Coal Project. It is the understanding of AEE that during 1999 Luscar should be submitting the Final Project Report to the B.C. Environmental Assessment Office. Following certification of the project, it is the understanding of AEE that the entire surface water and water quality program may need to be revised to meet the construction plan for the mine.

2.0 WORK PROGRAM AND BUDGET

The revised budget presented in Table 1 is based on the scope of services requested by Luscar at the January 26th, 1999 meeting. The work program proposed for 1999 is as follows:

Surface Water Flow

- Concentration of the base program on the winter and summer low flow periods.
- Monitoring of low flows on Four Creek, Hubert Creek, ~~Holpo Creek~~, Upper Goathorn Creek and Lower Goathorn Creek. No monitoring will be conducted on Tenas Creek, Telkwa River, and the Bulkley River.
- Monitoring of peak flows at the streams using crest gauges already installed at all of the existing sites. To conduct this portion of the required work, AEE must visit all sites during April to ensure that the sites are ready for the peak flow period (i.e. Checking of staff gauges and crest gauges). During November time has been allocated for conducting a final site visit to all sites to determine their condition prior to winter.
- A cost option has been prepared to operate the data loggers and pressure transducers at the continuous monitoring sites and to conduct a single high flow discharge measurement.

Water Quality

- Sampling of baseline parameters for the two low flow periods only.
- Sampling of metals for the two low flow periods.

Selenium sampling was requested to be deleted from the scope of work for 1999, however, the sampling for this was completed prior to receiving notification from Luscar. It is the expectation of AEE that the costs of this sampling will be paid by Luscar as the work was conducted at the request of Mr. Jerry Demchuck, the environmental coordinator for the Telkwa Coal Project. All future requests for increased sampling will not be initiated by AEE until a signed order to proceed with the work has been received from Luscar.

Not true.

Reporting

AEE proposes to conduct reporting for the 1999 sampling program following each monitoring trip. A data memo will be issued to Luscar presenting the results of the monitoring trip. This information will assist Luscar in public meetings by providing the most up to date information on the project. The costs of reporting for the optional water flow monitoring program are included in Table 1 as an additional cost of approximately $530.00 per monthly report.

Project Management

Project management involves dealing with items such as cost control, client liaison, responding to requests for extra work, and interfacing with other consultants working for Luscar on the proposed Telkwa Coal Mine. For the 1999 sampling program, AEE proposes to conduct each portion of the project as separate tasks. On receiving a request for extra work, AEE will issue to Luscar for approval, a change of work order along with an expected budget to complete the extra work. Project management for the 1999 program will be conducted by Mr. Scott Davidson, M.Sc., P.Geo. of the Smithers office. Mr. Gary Beckstead and Mr. Dennis Trotter will provide technical input and review to the project as required.

3.0 CLOSURE

We thank you for the opportunity to provide engineering and environmental services to this project and look forward to continuing to work with Luscar on the proposed Telkwa Coal Mine during 1999. If you have any questions or require further information concerning this project, please call Scott Davidson at (250) 847-8783 or Gary Beckstead at (403)235-8118.

Yours sincerely,

AGRA Earth & Environmental Limited

Disbursements		$ -	$ 100.00	$ 100.00	$ 100.00	$ -	$ -	$ -	$ 100.00	$ 100.00	$ -	$ 100.00	$ -	$ 600.00
Project Management	1,8													
Labour		$ 780.00	$ 405.00	$ 405.00	$ 405.00	$ 405.00	$ 405.00	$ 405.00	$ 405.00	$ 405.00	$ 405.00	$ 405.00	$ 405.00	$ 5,235.00
Disbursements		$ 100.00	$ 100.00	$ 100.00	$ 100.00	$ 100.00	$ 100.00	$ 100.00	$ 100.00	$ 100.00	$ 100.00	$ 100.00	$ 100.00	$ 1,200.00
Total (Required Work)		$2,305.20	$ 8,491.00	$ 1,902.00	$3,426.50	$ 505.00	$ 505.00	$ 505.00	$4,756.50	$ 5,262.50	$ 505.00	$2,002.80	$ 505.00	$ 30,671.50
Total (Optional Work)		$ -	$ -	$ -	$1,860.00	$ 4,223.00	$ 2,063.00	$ 2,063.00	$2,063.00	$ 2,063.00	$2,063.00	$1,625.00	$ -	$ 18,023.00

Assumptions:

1 The above budget are based on the Fw rate schedule
2 The summer low flow period extends over August and September
3 The winter low flow period extends over February and March
4 The Optional Water Flow Sampling would result in 1 monthly monitoring visit per month and 1 discharge measurement during May 1999
5 The January water quality sampling costs represent the Selenium sampling
6 Reporting costs are for the preparation of summary reports following completion of required project tasks
7 Reporting Costs from the Optional Water Flow program would be approximately $530.00 per monthly update report
8 Internal Disbursements are to be billed at Cost Plus 10% with information on these disbursements provided to Luscar Ltd..
9 Disbursements listed under Water Flow and Water Quality are estimates for sampling equipment and vehicle expenses and do not include 10% handling charge.
10 All Laboratory Analysis is to be directly billed to Luscar Ltd.

Attention: Mr. Allan Flemming, P.Eng. Fax: (403) 420-4089

Dear Mr. Flemming:

Re: Telkwa Coal Mine
1999 Budget

1.0 SURFACE WATER MONITORING

As per the January 19th, 1999 discussion between Gary Beckstead of AGRA Earth & Environmental Limited (AEE) and Allan Flemming of Luscar Ltd. (Luscar), AEE is pleased to present this "**draft**" budget for the 1999 baseline water flow and water quality program for the proposed Telkwa Coal Project. This draft will be discussed with you at your office on January 26th, 1999. It is the understanding of AEE that during 1999 Luscar should be submitting the Final Project Report to the B.C. Environmental Assessment Office. Following certification of the project, it is the understanding of AEE that the entire surface water and water quality program will need to be revised.

2.0 WORK PROGRAM AND BUDGET

AEE's proposed 1999 work program is intended to allow for revision of the program during the year. Table 1 presents the monthly budget breakdown for 1999.

The work program proposed for 1999 is as follows:

Surface Water Flow

- Three winter low flow discharge measurements on the Telkwa River;
- Five free flow period discharge measurements at all sites[1];
- An initial site visit during spring followed by an installation trip to sites; and
- Seven trips to perform routine maintenance and downloading of continuous sites.

---

[1] The Telkwa River will only be measured during three of the five free flow discharge measurement trips

Water Quality

- Four trips are scheduled for seasonal baseline water quality sampling;
- One sediment collection trip is included with the seasonal baseline trips; and
- High frequency revised metals sampling program started in 1998 is currently scheduled for continuation in 1999[2].

Reporting

AEE proposes to conduct reporting for the 1999 sampling program at approximately four month intervals. By separating the reporting into smaller pieces, AEE expects to be able to realize cost savings over the previous annual report preparation costs. The issuing of three data reports during 1999 will also allow for easier revision of the sampling program following submittal of the Final Project Report and project certification.

Project Management

Project management involves dealing with items such as cost control, client liaison, responding to requests for extra work, and interfacing with other consultants working for Luscar on the proposed Telkwa Coal Mine. AEE has found that the project management required for the proposed Telkwa Coal Mine exceeded the original budget estimate. Based on an analysis of previous work, AEE has revised its method of project management for the 1999 sampling program. AEE feels that the revisions made to project management will simplify tracking of costs for each phase of the project.

Previous requests for extra work conducted by AEE on the Telkwa Coal project were often accompanied by a directive to bill the work to the existing sampling program budget. For the 1999 sampling program, AEE proposes to conduct each portion of the project as separate tasks. On receiving a request for extra work, AEE will issue to Luscar for approval, a change of work order along with an expected budget to complete the extra work.

3.0 CLOSURE

We thank you for the opportunity to provide engineering and environmental services to this project and look forward to continuing to work with Luscar on the proposed Telkwa Coal Mine during 1999. It is the understanding that AEE and Luscar will discuss this draft budget during

---

[2] The revised sampling program is intended to determine the optimum sampling frequency for project. Following the winter and spring sampling trips, AEE should have sufficient data to determine the optimum sampling frequency allowing for modification of the water quality program.

a meeting scheduled for Tuesday, January 26th, 1999. Other items which I would like to discuss with you on Tuesday include:

- miscellaneous disbursement charge (% of fees); and
- possible shift of Project Manager to Scott Davidson in Smithers.

If you have any questions or require further information prior to this meeting, please call Gary Beckstead at (403)235-8118.

Attention: Mr. Allan Flemming, P.Eng.

Dear Mr. Flemming:

Re: Telkwa Coal Mine
1999 Budget

1.0 SURFACE WATER MONITORING

As per the January 19th, 1999 discussion between Gary Beckstead of AGRA Earth & Environmental Limited (AEE) and Allan Flemming of Luscar Ltd. (Luscar), AEE is pleased to present this "draft" budget for the 1999 baseline water flow and water quality program for the proposed Telkwa Coal Project. This draft will be discussed with you at your office on January 26th, 1999. It is the understanding of AEE that during 1999 Luscar should be submitting the Final Project Report to the B.C. Environmental Assessment Office. Following certification of the project, it is the understanding of AEE that the entire surface water and water quality program will need to be revised.

2.0 WORK PROGRAM AND BUDGET

AEE's proposed 1999 work program is intended to allow for revision of the program during the year. Table 1 presents the monthly budget breakdown for 1999.

The work program proposed for 1999 is as follows:

Surface Water Flow

- Three winter low flow discharge measurements on the Telkwa River;
- Five free flow period discharge measurements at all sites[1];
- An initial site visit during spring followed by an installation trip to sites; and
- Seven trips to perform routine maintenance and downloading of continuous sites.

---

[1] The Telkwa River will only be measured during three of the five free flow discharge measurement trips

Attention: **Mr. Allan Flemming, P.Eng.**
Manager, Special Projects

Dear Mr. Flemming:

Re: **Lakewood and Geneq Dataloggers in Relation to the Y2K Problem** (Telkwa)

We have recently been in contact with Lakewood Systems Ltd. and Geneq Inc. with regard to the problems which may occur as a result of the operation of their dataloggers into the year 2000. The status of each datalogger make is discussed below.

Lakewood has indicated that there will be no hardware modifications required. However, new software will be required to run the Lakewood dataloggers. The current LS-4 software will not allow the datalogger to be programmed correctly, nor will it allow the datalogger's time clock to be set correctly. All users must update their software to LS-4 Version 4.5 prior to the year 2000. This software will be posted on the Lakewood website (http://www.lakewood.com) in the near future and can be downloaded free of charge.

The Unidata Starloggers supplied by Geneq will not have a date problem with the year 2000 as the Starloggers calculate dates based on the number of scans from 1980. Therefore, the year will be calculated correctly. More specific information is available from the Unidata web site (http://www.unidata.com.au). Version 2 and 3 of the Starlog software are Y2K compliant. These programs are updated on a continual basis and are available on the website.

AEE will continue to monitor the progress made with the Y2K software at Lakewood. We will also ensure that the most current software is downloaded from each of these websites and used in future flow monitoring at Telkwa.

Should additional information be required with regard to this problem, you can contact Doug Calvert at Lakewood ((403)462-9110) or via e-mail at mail@lakewood.com or Steve Biduk at Geneq ((604)739-0889).

Sincerely,

AGRA Earth & Environmental Limited

Attention: Mr. Allan Flemming, P.Eng.

Dear Mr. Flemming:

Re: Telkwa Coal Mine
Hydrological Analyses

Further to our letter of October 6, 1998, and our discussions, some additional costs have appeared which were not included in that letter. These costs are as follows:

1. Chemex Labs water quality analyses ($4,788.30, as per the subsequent October 30, 1998 invoice).

2. Fees for Westmacott, McKay, Dick, Beckstead ($823.75) for completion of the 200 year flood assessment that Jerry Demchuk had commissioned. This report was finalized on September 28, 1998, immediately prior to the October 6 letter.

3. A significant portion of the 36 hours of Dennis Trotter's time in the October 30, 1998 invoice concerned ongoing discussions and data analysis in response to requests from Steve Day.

These subsequent costs of $9,212.05 plus GST had not been included in the forecast total. We should not require the entire amount to complete the outstanding deliverable, namely the 1998 monitoring report. For preliminary budgeting purposes, let us say that the total budget be increased to $210,000 from $203,853.64.

The 1998 monitoring report is nearing completion. It will be ready for internal technical review by January 20. It should be ready for final issue by January 29, 1999.

Scott Davidson and I are preparing an outline of tasks and associated costs for the 1999 program, as discussed with you earlier. We hope to have a draft ready by January 22, 1999. We can discuss the draft when we meet in your office on January 26, 1999.

We thank you for the opportunity to provide engineering and environmental services to this project. If you have any questions or require further information, please call the undersigned at 235-8118.

Yours sincerely,

AGRA Earth & Environmental Limited

Calgary, Alberta T2P 3V4

Attention: Mr. Al Fleming, P.Eng.

Dear Mr. Fleming:

Re: Response to BC Ministry of Environment Lands and Parks letter
July 23, 1998
Telkwa Coal Mine Surface Water Monitoring Program 1997

Further to our discussions with Jerry Demchuk, Environmental Advisor to Luscar/Manalta on November 5, 1998, AGRA Earth & Environmental Limited (AEE) is pleased to respond to the comments presented in the above-noted letter. We appreciate Mr. Obedkoff's comments and suggestions in the spirit of improving the quality of the surface water monitoring program where it is required. Many of his concerns relate to the volume of data available following the first year of the program. Where possible these comments will be considered in the analysis and assessment of the year 2 monitoring report, which will be prepared soon.

AEE has tried to purchase the Manual of Standard Operating Procedures for Hydrometric Surveys in British Columbia through our contacts in Prince George and Smiths over the past year; however the document has not been available until recently. We have now ordered copies and will use this publication for reference. Thanks to Mr. Obedkoff for the "heads up" that the publication is now available.

The responses to each of the individual comments for specific sections of the 1997 Surface Water Monitoring Report are presented below.

1.2 *Federal Water Survey of Canada (WSC) and Resources Inventory Branch (RIB) personnel should also be consulted for advice on hydrometric data collection procedures.*

AEE has established communications Ed Link of the WSC office in Terrace. We have discussed procedures with him and will continue to use him as a resource, when and if required.

It is our understanding that the RIB is located only in Victoria. Subject to your consent AEE will make contact with Mr. Obedkoff of the RIB.

2.1 *Include the WSC hydrometric station on Simpson Creek (08EE012). Is site C below the Tenas North Pit? If not, it should be below its outflow.*

DRAFT

AEE used data for Simpson Creek in the derivation of a regional flood frequency relationship. Otherwise, to date the data for this stream has not been used extensively as the Simpson Creek drainage basin lies outside the basin draining the Telkwa Project area. However, we will consider the use of the data further should the need arise.

Site C is located on Four Creek east of north tip of North Tenas pit. The location of the outflow point from the pit is unknown at this time. (get pit design from Al/Jerry and find out where outflow is.) Gaugung site locations will be reviewed critically to ensure location provides useful/reliable information once the project reaches the Certificate level.

3.1.3 *Stage-discharge curves must be based on measured points only.*

Only 7 months duration of data were available at the time the year one data report was prepared. IN the preparation of the 2nd year monitoring report, additional measurements from the 1998 field season will be available and used to confirm the results from the previous year. AS such it may prove necessary to evaluate and revise some of the data from the previous year based on the results from 1998. We appreciate the comment on this particular data plot, and will check the data again.

3.1.4 *The datalogger record is not coincident with staff gauge readings, except for three points; the calculated discharges are thus questionable. The datalogger must be calibrated at the site with hydrometric levelling of staff gauges and benchmarks. The datalogger and staff gauge level readings must be coincident, if not, an error must be applied to form corrected gauge heights before discharges are calculated.*

The data logger was tied in to local benchmarks. These surveys were conducted in 1997 and 1998. At this site there is a possibility that some stage readings may be relative to one staff gauge and some to another staff gauge. (Two staff gauges were established att he site to cover low and high stages. The data will be reviewed to ensure that the proper staff gauge was referenced and so that the transducer and staff gauge records correlate properly.

3.1.5 *Consult WSC or RIB personnel for a cost estimate of a cableway.*

WSC staff in Terrace have been consulted regarding the construction of a cableway across the Telkwa River. Cost estimates have been prepared, and were provided to MCL/LL on date. Long term site location needs to be determined relative to planned discharge (outfalll) points at which time a cableway will be considered. In the meantime the discharge data from the Telkwa River gauge can be added to the WSC Gaothorn Creek gauge data to give estimates of river discharges in the lower reach of the river.

3.3.4 *As per comments for 3.1.4*

DRAFT

AEE will take a second look at the data for Four Creek.

3.9.1 *What is the hydrologic purpose of an ephemeral stream hydrometric station for this project? If the gauge is for mines operations or water management, then it has a purpose.*

The Tailings Pond gauge was established on the ephemeral stream (called Tailings Pond Creek) below the proposed pond outlet and approximately 500 m downstream of present tailings disposal area. The intent of the data gathering for this station was to provide discharge data to facilitate the derivation of a water balance. for the proposed tailings pond. It should be noted that as the design of the facility has progressed, the size of the proposed tailings pond has shrunk from 100 ha to 30 ha

5.0 *Delete the last sentence of the third paragraph. The stage data collected may not lead to good quality discharge data.*

AEE will take under advisement the comments provided relative to sections 3.1.4 and 3.3.4. These items will be reviewed as discussed above. Also, as more discharge data is obtained, the rating curves will be improved. This will provide an opportunity to review previous estimates of discharge from the historical stream gauge height records.

We thank you for the opportunity to provide engineering and environmental services to this project. If you have any questions or require further information, please call the undersigned at 235-8118.

Yours sincerely,

Attention: Mr. Al Fleming, P.Eng. Fax: 269-8075

Dear Mr. Fleming:

Re: Budget Update
Telkwa Coal Mine
Hydrological Analyses

Further to our telephone conference call on October 2, 1998 with you and Jerry Demchuk, AGRA Earth & Environmental Limited (AEE) is pleased to provide you with a summary of the hydrological work you requested for the remainder of the calendar year. It is understood that Manalta Coal Ltd. (MCL, and/or its present owner, Luscar Ltd.) wish to have a single amendment to the existing contract for the remainder of this year's work related to the Telkwa Coal Mine Project.

A total of $25,182 is required to complete activities presently authorized by MCL for 1998. Table 1, attached, summarizes the individual tasks.

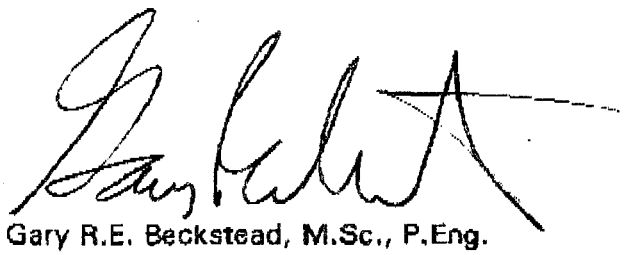
This estimate reflects the present monitoring program and does not include provision for changes to stations or station locations that may be required following granting of the Project Certificate.

The present contract value is $170,697.05, as amended by Change Order #5 (Oct. 2, 1997). Billings under this contract have totalled $178,671.64. As discussed October 2, 1998, the project is therefore over-billed $7,974.59. The outstanding work presented in Table 1 totals $25,182.00. The required adjustment to the contract is therefore $33,156.59. The resultant contract value following the revision is therefore $203,853.64.

If the program is continued to February 1999, the following additional components would be required: metals sampling ($8,720), regular monitoring and water quality sampling and analysis ($4,622 or less, depending on access and whether streams are flowing or frozen solid) , low-flow discharge measurements on the Telkwa River (potentially 2 measurements at $1,200 per

measurement) and additional data analysis and reporting ($4,000). The total for extending the program to February, 1999 is estimated at $19,742 (on top of the 1998 budget discussed above).

2.0 SCHEDULE



AEE will complete the work (i.e., reporting) by January 31, 1999. The actual field work will be completed by the end of November or the first week of December, 1998.

3.0 CLOSURE

We thank you for the opportunity to provide engineering and environmental services to this project. If you have any questions or require further information, please call the undersigned at 235-8118.

Yours sincerely,

AGRA Earth & Environmental Limited

TABLE 1
Remaining Tasks and Costs for 1998
Surface Water Monitoring Program

Task	Description	Cost
1	Metals Sampling. Additional metals sampling program, scheduled for late October and early November, 1998[1], as per the June 16, 1998 letter.	$8720
2	Regular flow Monitoring. Flow measurement, water quality sampling and analysis and data download from dataloggers[1] at the end of October as per October 24, 1997 fax to J. Demchuk.	$4622
3	Regular flow Monitoring. Flow measurement data download from dataloggers and removal of water level transducers and dataloggers for the winter season at the end of November or the first week of December as per October 24, 1997 fax to J. Demchuk.	$1190
4	Reporting. Preparation of annual data report to the end of December, 1998 and incorporate the 1997 and 1998 data into a single summary report, as directed.	$10,000
5	Project Management. QA/QC and financial management of the work, as per October 24, 1997 fax to J. Demchuk..	$2190
Total		**$25,182**

[1] The work for Tasks 1 and 2 will be scheduled at the same time to reduce travel and time expenditures. Special laboratory analyses of water quality samples are included in Tasks 1 and 2.

Dear Sir:

Re: ***Work Plan for Geotechnical and Hydrogeological Services 1997 Program, Tenas Creek Area, British Columbia***

1.0 INTRODUCTION

Piteau Engineering Ltd. (Piteau) is pleased to present our draft proposal and workplan for the above project. This proposal addresses the 1997 geotechnical, hydrogeologic and hydrologic workplans for the Tenas Pit and Pit 3 areas, and was developed in consultation with Manalta Coal Ltd. (Manalta) based on our meeting of June 13, 1997. These workplans fulfill the groundwater and water quality information requirements outlined on the draft project specifications for the Telkwa Coal project provided to us by Manalta.

The purpose of the 1997 geotechnical work program is to assess geotechnical conditions in the area of the Pit 3 waste dumps, the coal processing plant, and at the proposed location of the bridge crossing of the Telkwa River. The overall objective of the 1997 hydrogeological work program is to improve the level of understanding of baseline groundwater conditions in the areas of Tenas Pit and particularly Pit 3. The hydrological work will focus on development of a water balance for the post mining condition at Tenas Pit and Pit 3.

Information and data from previous investigations (Klohn Leonoff, 1985, Piteau 1994a and 1994b, Piteau 1995, Piteau 1996a and 1996b, and Piteau 1997a, 1997b, and 1997c) shall be referenced as much as possible to assist in attaining these objectives.

2.0 PROPOSED FIELD INVESTIGATIONS

The field investigations proposed within each facility area are briefly discussed below. As in previous geotechnical/hydrogeological investigations completed for the Telkwa coal project, the rotary drill to be used by Manalta for their coal exploration program will be adapted for the deep borehole drilling and proposed monitoring well installations. Moreover, piezometers will be installed within coal exploration boreholes. A backhoe will be utilized for the geotechnical investigations at the Pit 3 waste dumps, plant site and bridge crossing, coupled with interpretation of general overburden type and depth to bedrock from exploration holes.

Proposed hydrogeological borehole/monitoring well locations are shown in Figure 1.

2.1 PIT 3

2.1.1 GEOTECHNICAL INVESTIGATION OF WASTE DUMPS

The objective of the geotechnical investigation is to determine the lithology and basic soil parameters of the dump foundation. The investigation shall consist of the following:

- reconnaissance of the dump sites to verify terrain conditions, map surface water and springs, and to examine soil and rock exposures;
- excavation of approximately 5 test pits, up to 5 m deep, along the existing road in the central area of the dump to log soil units and collect soil samples; and,
- laboratory testing of soil samples, including moisture content, Atterberg limits, grain size and penetrometer strengths.

Depth to bedrock will be determined from exploration drill holes.

A brief report will be prepared documenting the investigations, geotechnical conditions, overall suitability of the site, and any limitations on dump development.

2.1.2 HYDROGEOLOGICAL INVESTIGATION

In view of the fairly complex hydrogeological setting at Pit 3, and in particular the potential importance of faults and fractures on groundwater flow, it is proposed that the groundwater monitoring network be expanded with the installation of six double piezometer nests (site # 3, 10, 15, 24, 28, and 52, see Figure 1). If possible, at one or two piezometer nest locations, efforts will be made to install a piezometer(s) directly within or adjacent to an identified fault zone.

The deeper piezometer will be completed in coal seam 2 while the shallow piezometer will be installed in coal seam 4. However at sites # 28 and #52, it is anticipated the deeper piezometer will be installed in seam 1. Following piezometer development, hydraulic conductivity testing will be performed. The piezometers will be sampled to determine groundwater quality, as well as to assess horizontal groundwater flow patterns, and vertical hydraulic gradients between the two coal seams.

Groundwater quality monitoring will be also be completed at the other existing piezometers (5 in total) completed within the Pit 3 area (i.e., T96R series piezometers). Groundwater samples will be analyzed for the same suite of chemical parameters previously analyzed for, and as specified by the B.C. Ministry of Environment.

Results from the 1997 hydrogeological program, together with hydrogeological information gathered from the aquifer test (discussed below) will be used to develop a better conceptual understanding of groundwater flow and groundwater quality within Pit 3.

2.1.3 AQUIFER TESTING PROGRAM

One of the key hydrogeological issues pertaining to the Telkwa Coal project is the potential influence of regional faults and fractures on groundwater flow. Moreover, related to this is the potential for impact of mining activities on local water wells. To address these issues, it is recommended that an aquifer test be conducted at a test well located within a suitable area of Pit 3 (location to be finalized).

Although the final design of the test well will be determined in the field, based on hydrogeological conditions, it is recommended that the pilot hole be drilled to a diameter of 200 mm (8"). This borehole diameter will permit installation of 150 mm (6") diameter water well casing and use of a submersible pump (5 or 7 hp) sufficient to adequately stress the aquifer. The decision as to whether to install well screen (compared with open hole) will be assessed during the borehole drilling. It is our understanding the test well will be drilled using a local water well contractor and that Manalta will be responsible for overseeing drilling activities. Consequently, we have not included costs for supervision of the drilling of the test hole.

It is recommended that the aquifer test consist of a 48 hour constant rate drawdown component followed by a 48 hour recovery component. In the event aquifer boundary conditions are identified, the drawdown component of the test would be extended to at least 72 hours. The constant rate test should be preceded by a 4 hour step drawdown test to evaluate well efficiency and to determine a suitable rate for the constant yield test. During the aquifer test, groundwater levels will be monitored in selected observation wells in Pit 3 and if possible, in domestic wells located within 2 km of the test well. Groundwater levels will be monitored manually using electric water level tapes as well as using pressure transducers and data loggers. A turbine and digital flow meter would be used to monitor groundwater pumping rates.

policy! require

Results from the aquifer test will permit determination of the hydraulic properties (i.e., transmissivity and storativity) of coal seam 2. This information will be used to refine estimates of the groundwater flow velocity in the coal seams and may provide insight into the role and importance of fractures and faults within the Pit 3 area. Potential effects of mining activities on nearby domestic wells will also be assessed.

2.1.4 GEOTECHNICAL LOGGING OF ROCK CORE

There is an opportunity for collection of geotechnical information of rock core during exploration drilling operations. It is thus proposed that a geotechnical engineer from Piteau (Vancouver)

spend one day on-site with Manalta geologists to provide training for the collection of geotechnical data (as required) during their drilling and logging operations.

Tamas ✓ missing?

2.1.5 HYDROLOGICAL ASSESSMENT

Sect 2.4

A preliminary water balance will be developed for Pit 3. The pit water balance methodology will be based on the procedures previously developed for Pits 7 and 8 (Piteau, 1994a). Estimates of groundwater inflows will be combined with estimates of surface water runoff to establish filling rates. As was the case for Pits 7 and 8, a sensitivity analysis will be conducted to establish the range of possible filling rates, taking into account uncertainties in groundwater inflow rates and wet/dry year scenarios.

2.2 COAL PROCESSING PLANT - GEOTECHNICAL INVESTIGATION

The objective of the geotechnical investigation is to provide data for confirming the feasibility of two potential sites and to develop preliminary designs. The investigation will consist of the following:

- excavation of approximately 6 test pits, 5 m deep, to be located along the perimeter of the 43 m x 16 m plant site configuration - log soil units and collect soil samples; and,
- laboratory testing of soil samples, comprising moisture content, Atterberg limits, grain size and penetrometer strengths, and if softer clay soils are found unconsolidated undrained triaxial and consolidation tests.

Depth to bedrock will be determined from exploration drill holes.

A brief report will be prepared documenting geotechnical conditions, and discussing options and providing relevant design parameters for the plant foundation.

2.3 BRIDGE ON TELKWA RIVER - GEOTECHNICAL INVESTIGATION

The objective of the geotechnical investigation is to confirm the geotechnical feasibility of crossing the river and to provide data for preliminary foundation design. The investigation will consist of the following:

- excavation of approximately 6 tests pits, 5 m deep, at 2 or 3 locations on each side of the river crossing to log soil units and collect soil samples;
- drilling 2 boreholes with the exploration rig: one on each bank (to bedrock or to 30 m deep in gravel, or 50 m deep in clay), logging of drill cuttings to determine soil type (gravels vs. sand vs. silt/clay); and,
- laboratory testing of soil samples, comprising moisture content, Atterberg limits, grain size and penetrometer strengths, and if softer clay soils are found, perform unconsolidated undrained triaxial and consolidation tests.

A brief report will be prepared on the investigation and geotechnical conditions encountered, and providing relevant foundation design parameters.

2.4 TENAS PIT

2.4.1 HYDROGEOLOGICAL INVESTIGATION

It is proposed that the groundwater monitoring network be expanded with the installation of two double piezometer nests near the north end of Tenas Pit (Figure 1). The deeper piezometer will be completed in coal seam 1 while the shallow piezometer will be installed in coal seam "c". Following piezometer development, hydraulic conductivity testing will be performed. The piezometers will be sampled to determine groundwater quality, and to estimate horizontal groundwater flow patterns, and vertical hydraulic gradients between the two coal seams.

Groundwater quality monitoring shall also be completed at all other existing piezometers (19 in total) completed within the Tenas Pit area (i.e., T95R, T96R, and TOB96 series piezometers).

Information garnered from the 1997 hydrogeological program will augment the existing hydrogeological database that exists for the Tenas Pit.

2.4.2 HYDROLOGICAL ASSESSMENT

A preliminary water balance will be developed for the Tenas Pit. The approach for the water balance will be the same as described for Pit 3 in Section 2.1.5.

3.0 COST ESTIMATE

The estimated cost of the investigation program is $118,405, exclusive of the GST. A detailed cost breakdown is provided on Table 1.

In developing these costs the following assumptions were made:

- all survey work (i.e., ground surface and top of piezometer casing elevation) will be arranged by Manalta;
- costs for borehole drilling, piezometer construction materials and excavation of test pits are not included;
- contractor costs for the drilling/installation of the test well and aquifer testing are not included; and,
- Piteau only charges for costs actually incurred. Any cost savings generated through more rapid program completion would be passed onto Manalta; conversely any additional costs due to unexpected or difficult subsurface conditions or down time from poor weather, would be charged at extra cost at the units rate listed in Table 1.

Additional assumptions in the cost estimate are presented in Table 1.

4.0 SCHEDULE AND REPORTING

The schedule of the work will coincide with Manalta's exploration program, which is presently understood to consist of a 3 week on/3 week off rotation, beginning July 15, 1997. Therefore, it

is anticipated scheduling for the geotechnical/hydrogeological field work and reporting will be as follows:

- July 21 to August 2, - Borehole drilling and piezometer installations (Pit 3 area); geotechnical investigations;
- Late-August to mid-September, - borehole drilling and piezometer installations (Tenas Pit area); aquifer testing program; groundwater sampling; and,
- October 30, - submission of draft reports summarizing results from the hydrogeological and geotechnical programs completed in 1997.

It is our understanding that results from the hydrogeological/hydrological investigations will form the basis for a stand alone report summarizing baseline hydrogeological conditions at the Tenas Pit and Pit 3. The reports will essentially augment the previous detailed baseline report prepared by Piteau (1997a). Information from the geotechnical investigations will be presented under separate cover.

5.0 CLOSURE

We trust this cost proposal is suitable for your present needs. If you have any questions, please do not hesitate to contact either of the undersigned or Dr. Tad Dabrowski.

Respectfully,

PITEAU ENGINEERING LTD.

Frederic B. Claridge, M.S., P.Eng.

Robert S. Clarkson, M.Sc., P.Geol.

Re: Telkwa Coal Project: Remaining Issues

This fax is to describe the scope of work developed in our January 8, 1999, meeting. The scope of work for the three issues we discussed is as follows:

Hydrology of Four Creek
There is concern over diversions on the ecosystem (most importantly fish) on Four Creek. The hydrology component will examine the pre- and post-development flows in the creek. Discussions with Dave Bustard will be required to determine the sensitivity of the aquatic community to these flow changes.

The hydrology for the Telkwa project collected to date has largely ignored the hydrology data collected on-site, since this data was previously too sporadic and of insufficient duration to answer questions concerning long-term hydrology (such as 1:200 year low flow events). However, given that a question specific to Four Creek has been posed, it will be necessary to integrate the regional flow information and the Four Creek monitoring data provided by Agra. Using this information, estimated monthly average and low flows (pre- and post-development) will be calculated. ← Luscar to do stats.

If the proposed diversions are likely to cause problems for the fishery, it may be necessary to examine alternate filling scenarios for the Tenas pits. For example, a structure could be constructed which would divert water to the pit only when a minimum flow level was achieved. This will require recalculation of the filling times for the Tenas pits.

Residual Moisture Content of Haul Road Surface No. Cirmac consulted
An estimate of the residual moisture content of the Haul road surface (soil surface) is required for the dust fall modelling. At present the model has been performed for a moisture content range of 4 to 11%, and the predicted dust fall has proven to be sensitive within that range. A literature review is required, along with some preliminary analysis specific to the weather conditions at the Telkwa area, to refine the data input.

Weathering Characteristics of Waste Rock
There is empirical evidence that the waste rock that will be generated at Telkwa is susceptible to breakdown due to weathering. It has therefore been suggested that the waste rock dumps will be self sealing as the waste rock weathers, resulting in surface water running off the dumps, rather than infiltrating them. A review of all current data available on the waste rock is required, with the purpose

of predicting the breakdown of the waste rock dump faces, the resulting permeability of the dump surface, and the resistance of the dump face to erosion.

Closure

Since these issues are all significantly different, we suggest that three separate letter reports would be suitable. We propose to issue a draft of the reports by February 5, 1999. Final copies to be issued 1 week after comments are received back from yourself. The cost estimate to perform this work is attached. Since this scope of work is a bit loose we emphasize that it is only an estimate, and believe that the cost will range between $5,000 and $10,000.

Attention: Allan Flemming, P.Eng.

Dear Mr. Flemming:

Re: Hydrology of Four Creek

INTRODUCTION

A previous report, *Water Management for the Telkwa Coal Project* (Piteau 1998, henceforward referred to as WMTCP), addressed the issue of hydrology in and around the proposed Telkwa Coal Project. In order to ensure the rapid filling of abandoned pits, the diversion of a number of creeks is anticipated. One of these, Four Creek, was identified by the British Columbia Ministry of Environment, Lands and Parks (MELP) as being of concern from a fisheries perspective. This letter addresses the issue of the hydrologic implications of the diversion of a portion of the upper drainage of Four Creek.

HYDROLOGY OF FOUR CREEK

Figure 1 shows the drainage sub-basins of Four Creek[1]. For analysis purposes, flows have been considered at the following locations:

---

[1] A discrepancy exists between the drainage area used in this report and that used in the WMTCP report. Previously, a drainage area of 13 km^2 was calculated using 1:50,000 topographical maps - 1:20,000 scale maps used in this report suggest a 10 km^2 drainage area.

1: the proposed diversion location into the Tenas Main Pit
2: two thirds of the drainage area
3: the mouth of Four Creek (confluence with Goathorn Creek)

Four Creek flow data was collected in 1997 (October-November) and 1998 (June-November). Of greatest hydrologic (and fisheries) concern are the relatively rare low flow events. The data record for Four Creek is not sufficiently long to permit the calculation of low-flow statistics, and thus the record must be supplemented by longer-term precipitation data and/or regional hydrologic data. These are discussed below.

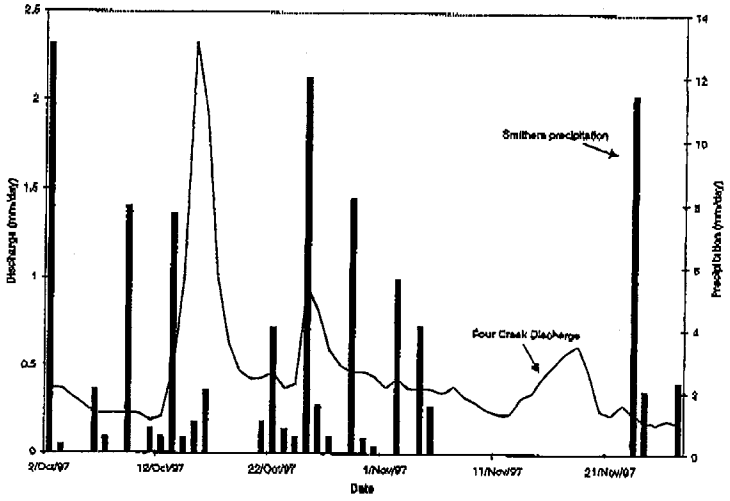

Figure 2: Four Creek discharge and Smithers Precipitation for 1997

CORRELATION OF TELKWA AREA RUNOFF AND SMITHERS PRECIPITATION

In general, the correlation between precipitation recorded at Smithers Airport and discharges in Simpson, Goathorn and Four Creeks is only fair. The discrepancy is more pronounced in the 1997 record than in 1998. Figure 2 and Figure 3 show the relationship between Four Creek discharges and Smithers precipitation for 1997 and 1998. Large precipitation events are not reflected in the discharge record, particularly after October 22. In addition, discharge in Four Creek increased in mid-November when no precipitation was recorded at Smithers.

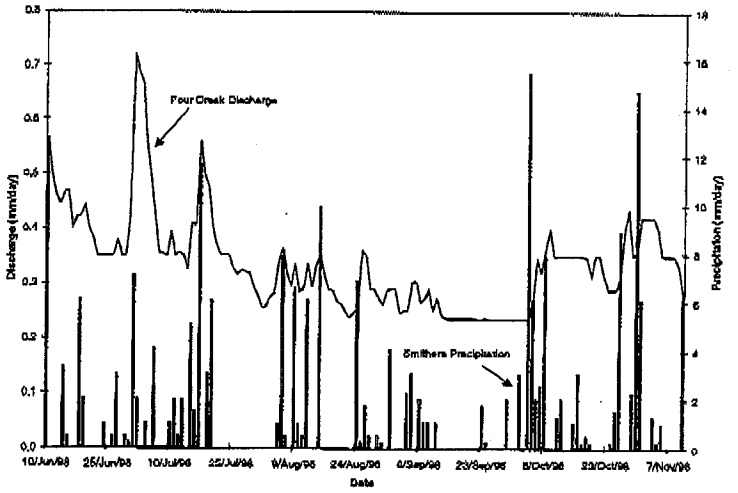

Figure 3: Four Creek Discharge and Smithers Precipitation for 1998

The timing of runoff and precipitation events for 1998 have a closer relationship than in 1997. Storm events in Smithers are generally reflected in the Four Creek discharge record. However, the magnitude of runoff response to precipitation is not well represented. Several large late-season precipitation events only result in minor increases in Four Creek discharge, as compared to early July where runoff is at its peak with only moderate precipitation recorded at Smithers. The record suggests that, at least on a daily time scale, precipitation recorded at Smithers is not representative of the precipitation received at Telkwa.

Over the longer-term (monthly or annually), however, the precipitation, however, the Smithers and Telkwa precipitation data appeared to correlate reasonably well. In the WMTCP report, precipitation recorded at Smithers (elevation 523 masl; 55 years of data) was compared to precipitation recorded at Telkwa (elevation 683 masl; 26 years of data) and Telkwa Coal Mine Road (elevation 670 masl; 3 years of data). Both Telkwa stations were discontinued over 10 years ago, however, the data suggests that the Telkwa area receives roughly 11% less precipitation than Smithers. Thus, the Smithers precipitation data was reduced by 11%, which was used to estimate precipitation, surface runoff and infiltration into the coal pits.

COMPARISON OF HYDROLOGY OF FOUR AND GOATHORN CREEKS

The WMTCP report identified four key gauged drainages in the Telkwa area:

- Canyon Creek Near Smithers (Environment Canada station #08EE014)
- Kathlyn Creek above Simpson Creek (08EE010)
- Simpson Creek at the Mouth (08EE012)
- Goathorn Creek near Telkwa (08EE008)

Two of Environment Canada's gauging stations, Canyon Creek and Kathlyn Creek, have been discontinued. Flow data for Goathorn, Simpson, and Four Creek are presented in Figure 4 and Figure 5. The data are presented as unit runoff (in mm). Thus, flows in the creeks have been corrected for drainage basin size.

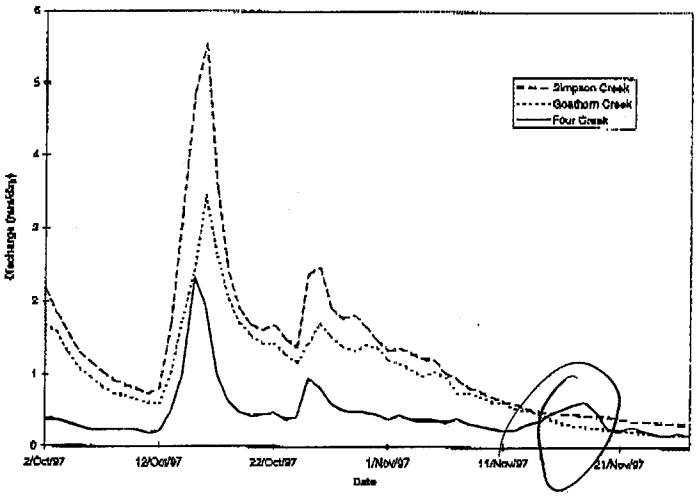

Figure 4: Comparison of Four, Simpson and Goathorn Creek average daily discharge for 1997

Data from Simpson Creek suggest that this basin is very "peaky" - a trait which was less marked in the Goathorn and Four Creek data. Thus, it appears that Goathorn Creek is a more appropriate comparison for Four Creek, and will be used in subsequent analyses.

Thus, to transform long-term Goathorn Creek data for use at the Four Creek site, a comparison of the 1997 data at the two sites was made[2]. The cumulative runoff at the Four Creek station was 23 mm, and at Goathorn Creek, 54 mm. This gives a ratio of 22.9/54.2 = 0.42. For 1998, the cumulative runoff for Four and Goathorn Creeks were 52 and 156 mm respectively, yielding a ratio of 0.33. The ratios for the 1997 and 1998 discharge records were averaged to produce a value of 0.38, which was applied to the Goathorn Creek data as a transformation.

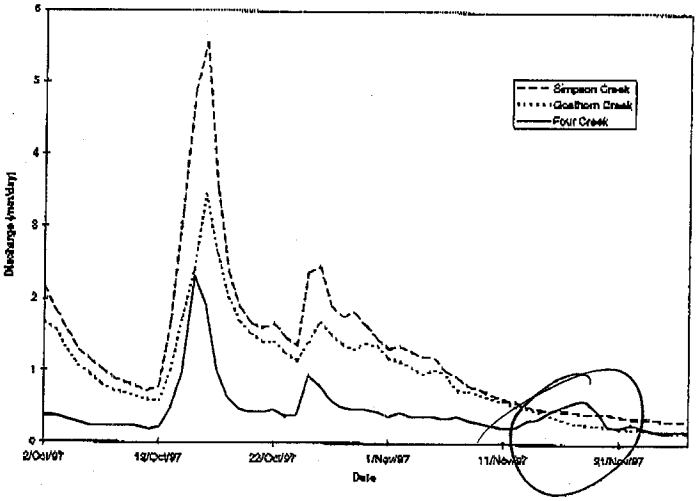

Figure 5: Comparison of Four, Simpson and Goathorn Creek average daily discharge for 1997

Table 1 shows the runoff coefficients for Goathorn and Four Creeks. These coefficients were calculated using Smithers precipitation data (decreased by 11% to account for differences between Smithers and Telkwa, as described previously). Runoff coefficients for Four Creek do not change from 1997 to 1998, remaining at 28%. In the WMTCP report, a runoff coefficient of 30% was adopted. This latter figure was challenged by the BC MELP, as 30% is a lower coefficient than has been determined in nearby gauged basins. However, the limited Four Creek flow data

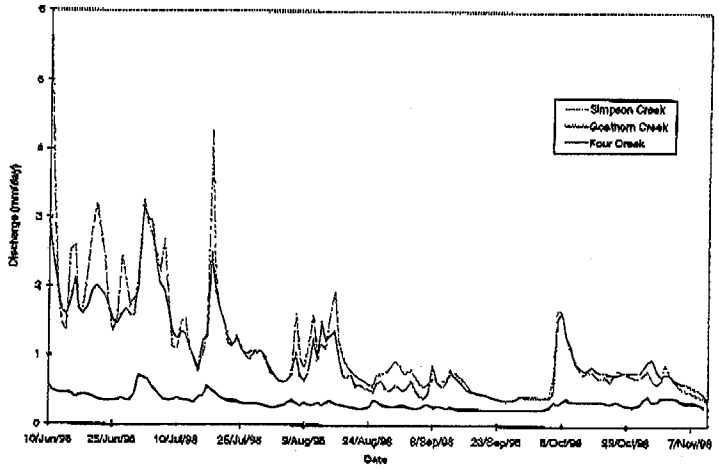

Figure 6: Comparison of Four, Goathorn and Simpson Creek Average Daily Discharge for 1998

Table 1 – Runoff coefficients for Four Creek and Goathorn Creek.

	1997			*1998*		
Basin	****Smithers Precipitation***	***Runoff***	***Runoff Coefficient***	****Smithers Precipitation***	***Runoff***	***Runoff Coefficient***
Four Creek	82 mm	23 mm	0.28	187 mm	52 mm	0.28
Goathorn Creek	82 mm	54 mm	0.65	187 mm	156 mm	0.83

Notes: Period of record for 1997 is October 2 to November 27.
Period of record for 1998 is June 10 to November 10.
* Decreased by 11% to transform to Telkwa area.

available suggest that a 30% runoff coefficient is indeed reasonable. The runoff coefficients for Goathorn Creek (relative to Smithers rainfall data) vary from 65% in 1997 to 83% in 1998. Our experience and knowledge of the area suggests that these figures are too high, since they imply that the Goathorn basin produces almost three times as much runoff (per square kilometre) as Four Creek. There are a number of potential sources for this discrepancy.

First, both basin aspect and elevation are expected to have a significant effect on discharge. The Goathorn Creek Basin has an altitude range of 1745 m (from 550 to 2295 masl) whereas the Four Creek basin has a range of only 670 m (from 700 to 1370 masl). If an orographic precipitation enhancement factor of roughly 40% per 1000 m is assumed (an average value for the Canadian Rocky Mountains, Quick and Pipes, 1996), then the Goathorn Creek watershed should receive significantly more precipitation. In addition, the Four Creek basin generally faces the northeast, where as the Goathorn Creek Basin faces both the northeast and the northwest. This variance in aspect will cause differences in snowpack accumulation and ablation.

Secondly, the influence of groundwater may be more pronounced in Goathorn Creek as it extends lower in the basin. Springs surfacing from fractures may augment flows in Goathorn Creek at elevations below the Goathorn/Four Creek confluence (700 masl).

Another factor is that Goathorn Creek is augmented by glacial runoff where as Four Creek is non-glaciated. Although the ice melt contribution during October and November is not expected to be great, there should be some water coming from glaciers due to pressure melting and perhaps internal storage.

TIMING OF RUNOFF

In general, the timing of the discharge record for Goathorn and Four Creeks compare favourably, as is illustrated in Figures 5 through 7. This suggests that the basins respond to meteorological events in a similar fashion, and thereby justifies the use of transformed Goathorn Creek discharge data as a surrogate for Four Creek data. Applying a time lag (at the daily scale) to the discharge does not improve this relationship.

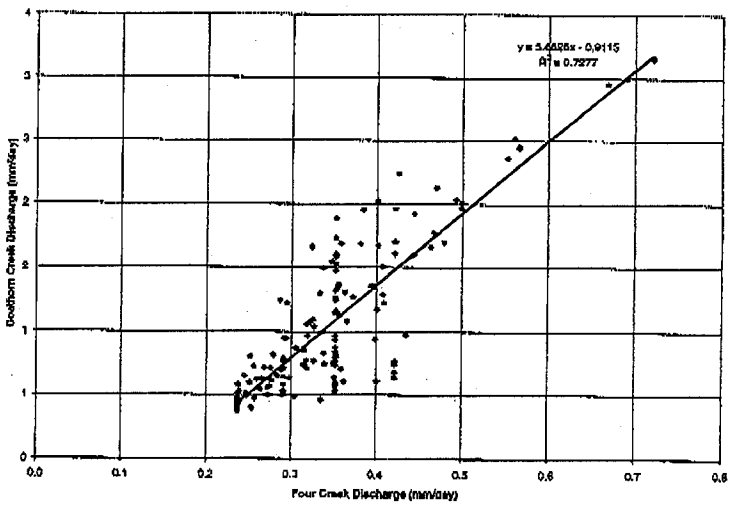

Figure 7: Relationship between Goathorn Creek and Four Creek average daily discharge

LOW FLOW ANALYSIS

Figure 8 shows the probabilities of mean annual low flows in Goathorn Creek. The data plotted are the lowest mean daily flows in Goathorn Creek (one mean daily flow for each year of record). For subsequent analysis purposes, the 1 in 10 year (10% probability) mean daily runoff of 0.045 mm/day was used as the reference. The runoff ratio of 0.38 was applied to estimate the 1 in 10 year low flow for Four Creek, giving a value of 0.017 mm/day. The average daily discharge for Goathorn Creek is 1.15 mm/day. Applying the ratio gives an estimated average daily runoff of 0.43 mm/day for Four Creek.

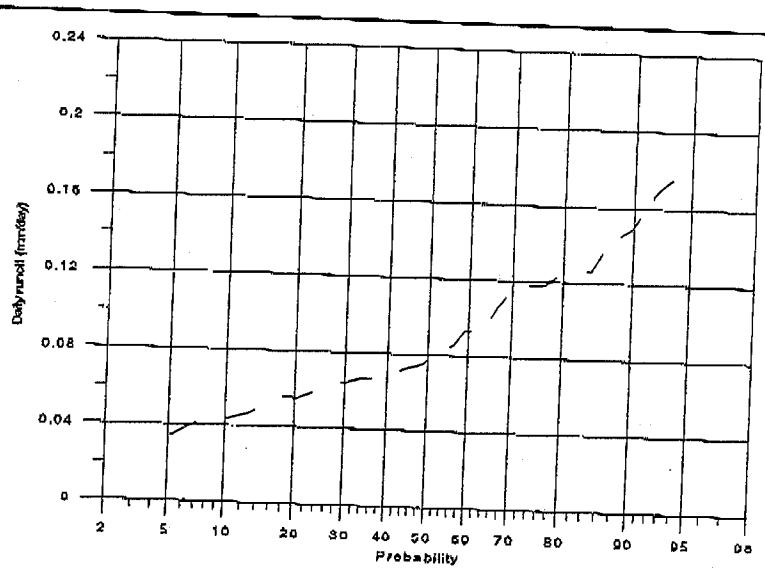

Figure 8: Mean daily low flow distribution in Goathorn Creek

The proposed diversion of the Four Creek tributary results in a reduction of roughly 18% of the total discharge area of Four Creek. Assuming that all areas of the basin behave in the same manner hydrologically, it can be assumed that the total discharge of Four Creek would also be reduced by 18%. Table 1 shows the estimated average daily and 1 in 10 year low flow for Four Creek at three stream locations assuming pre- and post-diversion scenarios. The influence of the proposed diversion on the flow of Four Creek is displayed graphically in the Appendix.

Table 2 - Estimated discharges for various locations along Four Creek.

Location	*% of original drainage area*	*Estimated Minimum 1 in 10 year Discharge (L/s)*		*Estimated Average Daily Discharge (L/s)*	
		with diversion	*without diversion*	*with diversion*	*without diversion*
At diversion	58	0.7	0.6	8.4	15
2/3 of basin length	74	0.9	1.3	22	30
At mouth	82	1.6	1.9	40	49

CONCLUSION

The use of Goathorn Creek data as a surrogate for Four Creek is reasonable provided that a transformation is applied (a value of 0.38 was used in this analysis). The two basins respond in a similar fashion in terms of timing, however, the Goathorn basin produces greater unit runoff. This may be a result of elevation, aspect, groundwater and/or icemelt.

The impact of the diversion on flows in Four Creek varies between the upper reaches and the mouth. At the mouth, only 18% of the original drainage is removed by diversion. At the point of diversion, however, 42% of the drainage (and hence flow) is removed. It is important to note that there is significant natural variability in the creek, ranging from a 1 in 10-year minimum of 1.9 L/s (assuming no diversion) to an average of 49 L/s.

It is possible to construct a diversion structure, which would guarantee a minimum flow in the creek. Only flows exceeding this minimum would be diverted into the pits. Withdrawals to the pits could therefore be restricted to higher flow periods, making the impact of the diversion relatively minor compared to natural creek variability.

Respectfully,

(INCLUDING COVER PAGE)

Allan,

Please find attached our first cut at a report on the effects of diversions of Four Creek. I recommend that the report be passed on to David Bustard for comments on potential fisheries impacts.

As I mentioned in our telephone conversation, there remains the issue of 1998 Four Creek monitoring data, which would give us a way to assess the relationship between low flows in Goathorn and Four Creeks. I believe that it is prudent that we wait for Agra to review this data prior to finalizing the report.

We have not included a map of the site, which is in production but was delayed due to problems in assessing drainage areas. Agra originally established the Four Creek gauge basin area using 1:50,000 topographic maps - the more recent maps provided by Manalta/Luscar have allowed us to more precisely define the drainage area. The upshot is some of the notes on the map are incorrect. I should also add that some of the numbers in the report will also change slightly, but I thought it more important to get you the report now despite the minor errors.

The major conclusion of the report should not change. In brief, the impact of the diversion will be relatively small in the lower watershed, and could be further minimized through the construction of a structure which would allow diversions only during higher flows. In the upper watershed, the effects of the diversion on flows are more substantial - it remains for the aquatics people to determine if these are changes would be significant for fish. Certainly, the natural variability of flows in the creek would appear to be a significant stressor for fish, particularly in the upper reaches.

If you have questions, please do not hesitate to call me or Alexi Zawadzki at (403)247-0200.

Attention: Allan Flemming, P.Eng.

Dear Mr. Flemming:

Re: ***Hydrology of Four Creek***

Introduction

We have reviewed the hydrology of Four Creek, and have reached the following preliminary findings. The following is intended for your review. We would be happy to incorporate the findings into a letter which would be suitable for dissemination to other parties such as BC MELP.

Figure 1 shows the drainage sub-basins of Four Creek. For analysis purposes, we have considered flows at the following locations:

1: the proposed diversion location into the Tenas Main Pit
2: two thirds of the drainage area
3: the mouth of Four Creek (confluence with Goathorn Creek)

Hydrology of Four Creek

The Telkwa Report (official name) presented a detailed analysis of the hydrology of the Telkwa region. Four key watercourses were identified in this work:

- Canyon Creek Near Smithers - 08EE014
- Kathlyn Creek above Simpson Creek - 08EE010

- Simpson Creek at the Mouth - 08EE012
- Goathorn Creek near Telkwa - 08EE008

Piteau has subsequently received flow measurement data from Agra for 1997 (Oct. 2-Nov. 27) and 1998 (Jun. 9-Oct. 19). Ideally this short-term data could be used in conjunction with regional flow data to accurately characterize the hydrology of Four Creek. However, our analysis of the Four Creek data shows that the 1997 data appears generally plausible, but the 1998 discharges are too low to be credible[1].

thurs/Fri of last week revised rating curve. re-issue 4-Creek

Comparison of hydrology of Four and Goathorn Creeks (1997)

Two of the Environment Canada gauging stations, Canyon Creek and Kathlyn Creek, have been discontinued. Flow data for Goathorn, Simpson, and Four Creek are presented in Figure 1. The data are presented as unit runoff (in mm). Thus, flows in the creeks have been corrected for drainage basin size. Basins with identical runoff coefficients (the percentage of precipitation which runs off into a creek) would plot as identical lines, regardless of basin size.

Data from Simpson Creek suggest that this basin is very "peaky" - a trait which was less marked in the Goathorn and Four Creek data. Thus, it appears that Goathorn Creek is a more appropriate comparison for Four Creek, and will be used in subsequent analyses.

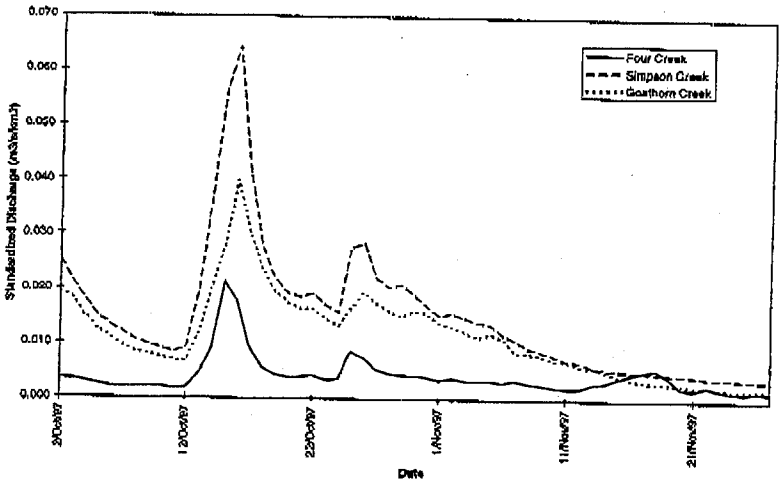

Figure 1: Comparison of Four Creek, Goathorn Creek and Simpson Creek Average Daily Discharge

Flow data for Goathorn Creek in 1997 was reported to be unreliable after November 15 due to ice conditions. Thus, to transform long-term Goathorn Creek data for use at the Four Creek site, a comparison of the 1997 data at the two sites was made. The cumulative runoff at the Four Creek station was 22.9 mm, and at Goathorn Creek, 54.2 mm. Thus, a ratio of 22.9/54.2 = 0.42 was applied to Goathorn data as a transformation. This implies that the Goathorn basin produces more than three times as much runoff (per square kilometre). There are a number of ~~potential sources of error~~ reasons for this discrepancy in this estimate.

First, Goathorn Creek is augmented by glacial runoff where as Four Creek is ice-free (termed *nival*). Although the ice melt contribution during October and November is not expected to be great, there will be some water coming from glaciers due to pressure melting and perhaps internal storage. A second source of error may be from the estimation of drainage area. Agra had

[1] Agra has indicated to us that the 1998 data had not been quality controlled (Kristi McKay, pers. comm.). This quality control is in process.

which is correct

estimated the drainage area of Four Creek as being 13 km^2 using 1:50,000 topographical maps. Komex had estimated the drainage area as being 10 km^2 using 1:20,000 maps provided by Manalta Coal Ltd/Luscar. The ramifications of an overestimation of drainage area are that discharge per unit area is underestimated. This may be the case as it is estimated that Four Creek produces three times less runoff than neighbouring Goat Creek. Goathorn.

Figure 2 shows the probabilities of mean annual low flows in Goathorn Creek. The data plotted are the lowest mean daily flows in Goathorn Creek (one mean daily flow for each year of record). For subsequent analysis purposes, the 1 in 10 year (10% probability) mean daily runoff of 0.045 mm/day was used as the reference. The runoff ratio of 0.32 was applied to estimate the 1 in 10 year low flow for Four Creek, giving a value of 0.012 mm/day. The average daily discharge for Goathorn Creek is 1.15 mm/day. Applying the ratio gives an estimated average daily discharge of 0.373 mm/day for Four Creek.

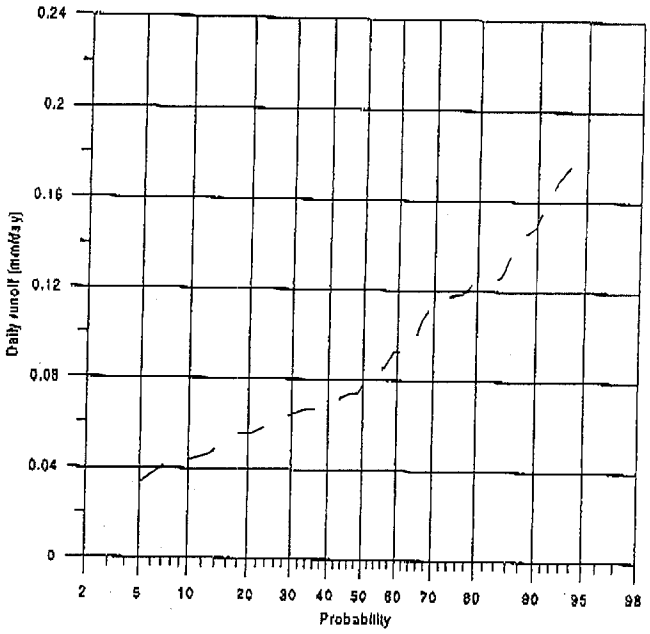

Figure 2: Mean Daily Low Flow Distribution in Goathorn Creek

The proposed diversion of the Four Creek tributary results in a reduction of roughly 18% of the total discharge area of Four Creek. Assuming that all areas of the basin behave in the same manner hydrologically, it can be assumed that the total discharge of Four Creek would also be reduced by 17%. Table 1 shows the estimated average daily and 1 in 10 year low flow for Four Creek at three stream locations assuming pre- and post-diversion scenarios.

or 18%

Table 1 - Estimated discharges for various locations along Four Creek.

Location	*% of original drainage area*	*Estimated Minimum 1 in 10 year Discharge (L/s)*		*Estimated Average Daily Discharge (L/s)*	
		with diversion	*without diversion*	*with diversion*	*without diversion*
At diversion	58	0.35	0.60	8.00	13.80
2/3 of basin length	74	0.89	1.20	21.20	28.65
At mouth	82	1.48	1.80	37.76	46.05

Conclusion

The impact of the diversion on flows in Four Creek varies between the upper reaches and the mouth. At the mouth, only 18% of the original drainage is removed by diversion. At the point of diversion, however, 42% of the drainage (and hence flow) is removed. It is important to note that there is significant natural variability in the creek, ranging from a 1 in 10 year minimum of 1.8 L/s (assuming no diversion) to an average of 46 L/s.

It is possible to construct a diversion structure which would guarantee a minimum flow in the creek. Only flows exceeding this minimum would be diverted into the pits. Withdrawals to the pits could therefore be restricted to higher flow periods, making the impact of the diversion relatively minor compared to natural creek variability.

Respectfully,
